- 12.55** A particular form of cinnabar (HgS) adopts the zinc blende structure, Figure 12.26. The length of the unit cell edge is 5.852 Å. (a) Calculate the density of HgS in this form. (b) The mineral tiemannite (HgSe) also forms a solid phase with the zinc blende structure. The length of the unit cell edge in this mineral is 6.085 Å. What accounts for the larger unit cell length in tiemannite? (c) Which of the two substances has the higher density? How do you account for the difference in densities?
- 12.56** At room temperature and pressure RbI crystallizes with the NaCl-type structure. (a) Use ionic radii to predict the length of the cubic unit cell edge. (b) Use this value to estimate the density. (c) At high pressure the structure transforms to one with a CsCl-type structure. (c) Use ionic radii to predict the length of the cubic unit cell edge for the high-pressure form of RbI. (d) Use this value to estimate the density. How does this density compare with the density you calculated in part (b)?
- 12.57** CuI, CsI, and NaI each adopt a different type of structure. The three different structures are those shown in Figure 12.26. (a) Use ionic radii, Cs⁺($r = 1.81 \text{ \AA}$), Na⁺($r = 1.16 \text{ \AA}$), Cu⁺($r = 0.74 \text{ \AA}$), and I⁻($r = 2.06 \text{ \AA}$), to predict which compound will crystallize with which structure. (b) What is the coordination number of iodide in each of these structures?

- 12.58** The rutile and fluorite structures, shown here (anions are colored green), are two of the most common structure types for ionic compounds where the cation to anion ratio is 1:2. (a) For CaF_2 and ZnF_2 use ionic radii, Ca^{2+} ($r = 1.14 \text{ \AA}$), Zn^{2+} ($r = 0.88 \text{ \AA}$), F^- ($r = 1.19 \text{ \AA}$), to predict which compound is more likely to crystallize with the fluorite structure and which with the rutile structure. (b) What are the coordination numbers of the cations and anions in each of these structures?

COVALENT-NETWORK SOLIDS (section 12.7)

- 12.63** Both covalent-network solids and ionic solids can have melting points well in excess of room temperature, and both can be poor conductors of electricity in their pure form. However, in other ways their properties are quite different.
- Which type of solid is more likely to dissolve in water?
 - Which type of solid can become an electrical conductor via chemical substitution?
- 12.64** Which of the following properties are typical characteristics of a covalent-network solid, a metallic solid, or both: (a) ductility, (b) hardness, (c) high melting point?
- 12.65** For each of the following pairs of semiconductors, which one will have the larger band gap: (a) CdS or CdTe , (b) GaN or InP , (c) GaAs or InAs ?
- 12.66** For each of the following pairs of semiconductors, which one will have the larger band gap: (a) InP or InAs , (b) Ge or AlP , (c) AgI or CdTe ?
- 12.67** If you want to dope GaAs to make an n-type semiconductor with an element to replace Ga, which element(s) would you pick?
- 12.68** If you want to dope GaAs to make a p-type semiconductor with an element to replace As, which element(s) would you pick?
- 12.69** Silicon has a band gap of 1.1 eV at room temperature.
- What wavelength of light would a photon of this energy correspond to?
 - Draw a vertical line at this wavelength in the figure shown, which shows the light output of the sun as a

- 12.59** The coordination number for Mg^{2+} ion is usually six. Assuming this assumption holds, determine the anion coordination number in the following compounds: (a) MgS , (b) MgF_2 , (c) MgO .

- 12.60** The coordination number for the Al^{3+} ion is typically between four and six. Use the anion coordination number to determine the Al^{3+} coordination number in the following compounds: (a) AlF_3 where the fluoride ions are two coordinate, (b) Al_2O_3 where the oxygen ions are six coordinate, (c) AlN where the nitride ions are four coordinate.

- 12.61** Classify each of the following statements as true or false:

- Although both molecular solids and covalent-network solids have covalent bonds, the melting points of molecular solids are much lower because their covalent bonds are much weaker.
- Other factors being equal, highly symmetric molecules tend to form solids with higher melting points than asymmetrically shaped molecules.

- 12.62** Classify each of the following statements as true or false:

- For molecular solids the melting point generally increases as the strengths of the covalent bonds increase.
- For molecular solids the melting point generally increases as the strengths of the intermolecular forces increase.

function of wavelength. Does silicon absorb all, none, or a portion of the visible light that comes from the sun?

- 12.70** Cadmium telluride is an important material for solar cells.
- What is the band gap of CdTe ?
 - What wavelength of light would a photon of this energy correspond to?
 - Draw a vertical line at this wavelength in the figure shown with Exercise 12.69, which shows the light output of the sun as a function of wavelength.
 - With respect to silicon, does CdTe absorb a larger or smaller portion of the solar spectrum?
- 12.71** The semiconductor GaP has a band gap of 2.2 eV. Green LEDs are made from pure GaP . What wavelength of light would be emitted from an LED made from GaP ?
- 12.72** The first LEDs were made from GaAs , which has a band gap of 1.43 eV. What wavelength of light would be emitted from an LED made from GaAs ? What region of the electromagnetic spectrum does this light correspond to: UV, visible, or IR?

12.73 GaAs and GaP ($E_g = 2.26$ eV) make solid solutions that have the same crystal structure as the parent materials, with As and P randomly distributed throughout the crystal. $\text{GaP}_x\text{As}_{1-x}$ exists for any value of x . If we assume that the band gap varies linearly with composition between $x = 0$ and $x = 1$, estimate the band gap for $\text{GaP}_{0.5}\text{As}_{0.5}$. What wavelength of light does this correspond to?

POLYMERIC SOLIDS (section 12.8)

12.75 What is a monomer? Give three examples of monomers taken from the examples given in this chapter.

12.76 The molecular formula of n -decane is $\text{CH}_3(\text{CH}_2)_8\text{CH}_3$. Decane is not considered a polymer, whereas polyethylene is. What is the distinction?

12.77 An ester is a compound formed by a condensation reaction between a carboxylic acid and an alcohol. Read the discussion of esters in Section 24.4 and then give an example of a reaction forming an ester. How might this kind of reaction be extended to form a polymer (a polyester)?

12.78 Write a chemical equation for formation of a polymer via a condensation reaction from the monomers succinic acid ($\text{HOOCCH}_2\text{CH}_2\text{COOH}$) and ethylenediamine ($\text{H}_2\text{NCH}_2\text{CH}_2\text{NH}_2$).

12.79 Draw the structure of the monomer(s) employed to form each of the following polymers shown in Table 12.5: (a) polyvinyl chloride, (b) nylon 6,6, (c) polyethylene terephthalate.

12.80 Write the chemical equation that represents the formation of (a) polychloroprene from chloroprene (polychloroprene is used in highway-pavement seals, expansion joints, conveyor belts, and wire and cable jackets);

Chloroprene

(b) polyacrylonitrile from acrylonitrile (polyacrylonitrile is used in home furnishings, craft yarns, clothing, and many other items).

Acrylonitrile

NANOMATERIALS (section 12.9)

12.87 Explain why “bands” may not be the most accurate description of bonding in a solid when the solid has nanoscale dimensions.

12.88 CdS has a band gap of 2.4 eV. If large crystals of CdS are illuminated with ultraviolet light, they emit light equal to the band gap energy. (a) What color is the emitted light? (b) Would appropriately sized CdS quantum dots be able to emit blue light? (c) What about red light?

12.89 True or false:

- (a) The band gap of a semiconductor decreases as the particle size decreases in the 1–10-nm range.
 (b) The light that is emitted from a semiconductor, upon external stimulation, becomes longer in wavelength as the particle size of the semiconductor decreases.

12.74 Red light-emitting diodes are made from GaAs and GaP solid solutions, $\text{GaP}_x\text{As}_{1-x}$ (see Exercise 12.73). The original red LEDs emitted light with a wavelength of 660 nm. If we assume that the band gap varies linearly with composition between $x = 0$ and $x = 1$, estimate the composition (the value of x) that is used in these LEDs.

12.81 The nylon Nomex®, a condensation polymer, has the following structure:

Draw the structures of the two monomers that yield Nomex®.

12.82 Proteins are polymers formed by condensation reactions of amino acids, which have the general structure

In this structure, R represents —H, —CH₃, or another group of atoms. Draw the general structure for a polyamino acid polymer formed by condensation polymerization of the molecule shown here.

12.83 What molecular features make a polymer flexible? Explain how cross-linking affects the chemical and physical properties of the polymer.

12.84 What molecular structural features cause high-density polyethylene to be denser than low-density polyethylene?

12.85 Are high molecular weights and a high degree of crystallinity always desirable properties of a polymer? Explain.

12.86 Briefly describe each of the following: (a) elastomer, (b) thermoplastic, (c) thermosetting plastic.

12.90 True or false:

If you want a semiconductor that emits blue light, you could either use a material that has a band gap corresponding to the energy of a blue photon or you could use a material that has a smaller band gap but make an appropriately sized nanoparticle of the same material.

12.91 Gold adopts a face-centered cubic structure with a unit cell edge of 4.08 Å (Figure 12.11). How many gold atoms are there in a sphere that is 20 nm in diameter? Recall that the volume of a sphere is $\frac{4}{3}\pi r^3$.

12.92 Cadmium telluride, CdTe, takes the zinc blende structure (Figure 12.26) with a unit cell edge length of 6.49 Å. There are four cadmium atoms and four tellurium atoms per unit cell. How many of each type of atom are there in a cubic crystal with an edge length of 5.00 nm?

ADDITIONAL EXERCISES

[12.93] A face-centered tetragonal lattice is not one of the 14 three-dimensional lattices. Show that a face-centered tetragonal unit cell can be redefined as a body-centered tetragonal lattice with a smaller unit cell.

12.94 Pure iron crystallizes with a body-centered cubic structure, but small amounts of impurities can stabilize a face-centered cubic structure. Which form of iron has a higher density?

[12.95] Introduction of carbon into a metallic lattice generally results in a harder, less ductile substance with lower electrical and thermal conductivities. Explain why this might be so.

12.96 As mentioned in Section 12.3, Ni_3Al is used in the turbines of aircraft engines because of its strength and low density. Nickel metal has a cubic close-packed structure with a face-centered cubic unit cell, while Ni_3Al has the ordered cubic structure shown in Figure 12.17. The length of the cubic unit cell edge is 3.53 \AA for nickel and 3.56 \AA for Ni_3Al . Use these data to calculate and compare the densities of these two materials.

12.97 For each of the intermetallic compounds shown in Figure 12.17 determine the number of each type of atom in the unit cell. Do your answers correspond to ratios expected from the empirical formulas: Ni_3Al , Nb_3Sn , and SmCo_5 ?

12.98 What type of lattice—primitive cubic, body-centered cubic, or face-centered cubic—does each of the following structure types possess: (a) CsCl , (b) Au , (c) NaCl , (d) Po , (e) ZnS ?

12.99 Tin exists in two allotropic forms: Gray tin has a diamond structure, and white tin has a close-packed structure. One of these allotropic forms is a semiconductor with a small band gap while the other is a metal. Which one is which? Which form would you expect to have the longer Sn—Sn bond distance?

[12.100] The electrical conductivity of titanium is approximately 2500 times greater than that of silicon. Titanium has a hexagonal close-packed structure, and silicon has the diamond structure. Explain how the structures relate to the relative electrical conductivities of the elements.

12.101 Silicon carbide, SiC , has the three-dimensional structure shown in the figure.

(a) Name another compound that has the same structure.

(b) Would you expect the bonding in SiC to be predominantly ionic, metallic, or covalent? (c) How do the bonding and structure of SiC lead to its high thermal stability (to $2700 \text{ }^\circ\text{C}$) and exceptional hardness?

[12.102] Unlike metals, semiconductors increase their conductivity as you heat them (up to a point). Suggest an explanation.

12.103 Teflon[®] is a polymer formed by the polymerization of $\text{F}_2\text{C}=\text{CF}_2$. Draw the structure of a section of this polymer. What type of polymerization reaction is required to form it?

12.104 Hydrogen bonding between polyamide chains plays an important role in determining the properties of a nylon such as nylon 6,6 (Table 12.5). Draw the structural formulas for two adjacent chains of nylon 6,6 and show where hydrogen-bonding interactions could occur between them.

12.105 Explain why X-rays can be used to measure atomic distances in crystals but visible light cannot be used for this purpose.

12.106 In their study of X-ray diffraction, William and Lawrence Bragg determined that the relationship among the wavelength of the radiation (λ), the angle at which the radiation is diffracted (θ), and the distance between planes of atoms in the crystal that cause the diffraction (d) is given by $n\lambda = 2d \sin \theta$. X-rays from a copper X-ray tube that have a wavelength of 1.54 \AA are diffracted at an angle of 14.22 degrees by crystalline silicon. Using the Bragg equation, calculate the distance between the planes of atoms responsible for diffraction in this crystal, assuming $n = 1$ (first-order diffraction).

12.107 Germanium has the same structure as silicon, but the unit cell size is different because Ge and Si atoms are not the same size. If you were to repeat the experiment described in the previous problem but replace the Si crystal with a Ge crystal, would you expect the X-rays to be diffracted at a larger or smaller angle, θ ?

[12.108] (a) The density of diamond [Figure 12.30(a)] is 3.5 g/cm^3 and that of graphite [Figure 12.30(b)] is 2.3 g/cm^3 . Based on the structure of buckminsterfullerene (Figure 12.47), what would you expect its density to be relative to these other forms of carbon? (b) X-ray diffraction studies of buckminsterfullerene show that it has a face-centered cubic lattice of C_{60} molecules. The length of an edge of the unit cell is 14.2 \AA . Calculate the density of buckminsterfullerene.

12.109 The valence band of a semiconductor is made up of bonding molecular orbitals and the conduction band of antibonding molecular orbitals. (a) Given this fact would you expect n-type doping to strengthen or weaken the bonds in a semiconductor? (b) Would you expect p-type doping to strengthen or weaken the bonds in a semiconductor?

INTEGRATIVE EXERCISES

- 12.110** The karat scale used to describe gold alloys is based on mass percentages. (a) If an alloy is formed that is 50 mol% silver and 50 mol% gold, what is the karat number of the alloy? Use Figure 12.18 to estimate the color of this alloy. (b) If an alloy is formed that is 50 mol% copper and 50 mol% gold, what is the karat number of the alloy? What is the color of this alloy?
- 12.111** Spinel is a mineral that contains 37.9% Al, 17.1% Mg, and 45.0% O, by mass, and has a density of 3.57 g/cm^3 . The unit cell is cubic with an edge length of 8.09 \AA . How many atoms of each type are in the unit cell?
- 12.112** (a) What are the C—C—C bond angles in diamond? (b) What are they in graphite?
- [12.113]** Employing the bond enthalpy values listed in Table 8.4, estimate the molar enthalpy change occurring upon (a) polymerization of ethylene, (b) formation of nylon 6,6, (c) formation of polyethylene terephthalate (PET).
- [12.114]** Although polyethylene can twist and turn in random ways, the most stable form is a linear one with the carbon backbone oriented as shown in the following figure:

The solid wedges in the figure indicate bonds from carbon that come out of the plane of the page; the dashed wedges indicate bonds that lie behind the plane of the page.

- (a) What is the hybridization of orbitals at each carbon atom? What angles do you expect between the bonds?
- (b) Now imagine that the polymer is polypropylene rather than polyethylene. Draw structures for polypropylene in which (i) the CH_3 groups all lie on the same side of the plane of the paper (this form is called isotactic polypropylene); (ii) the CH_3 groups lie on alternating sides of the plane (syndiotactic polypropylene); or (iii) the CH_3 groups are randomly distributed on either side (atactic polypropylene). Which of these forms would you expect to have the highest crystallinity and melting point, and which the lowest? Explain in terms of intermolecular interactions and molecular shapes.
- (c) Polypropylene fibers have been employed in athletic wear. The product is said to be superior to cotton or polyester clothing in wicking moisture away from the body through the fabric to the outside. Explain the difference between polypropylene and polyester or cotton (which has many —OH groups along the molecular chain) in terms of intermolecular interactions with water.
- 12.115** (a) In polyvinyl chloride shown in Table 12.5, which bonds have the lowest average bond enthalpy? (b) When subjected to high pressure and heated polyvinyl chloride converts to diamond. During this transformation which bonds are most likely to break first? (c) Employing the values of average bond enthalpy in Table 8.4, estimate the overall enthalpy change for converting PVC to diamond.
- [12.116]** Silicon has the diamond structure (Figure 12.30(a)) with unit cell edge length of 357 pm and eight atoms per unit cell. (a) How many silicon atoms are there in 1 cm^3 of material? (b) Suppose you dope that 1-cm^3 sample of silicon with 1 ppm of phosphorus that will increase the conductivity by a factor of a million. How many milligrams of phosphorus are required?
- 12.117** KCl has the same structure as NaCl. The length of the unit cell is 357 pm . The density of KCl is 1.984 g/cm^3 , and its formula mass is 74.55 amu . Using this information, calculate Avogadro's number.
- 12.118** Look up the diameter of a silicon atom, in \AA . The channel length in a Pentium 4 processor chip is 65 nm long. How many silicon atoms does this correspond to?

WHAT'S AHEAD

13.1 THE SOLUTION PROCESS

We begin by considering what happens at the molecular level when a substance dissolves, paying particular attention to the role of *intermolecular forces*. Two important aspects of the solution process are the natural tendency of particles to mix and changes in *energy*.

13.2 SATURATED SOLUTIONS AND SOLUBILITY

We learn that when a *saturated solution* is in contact with undissolved solute, the dissolved and undissolved solutes are in *equilibrium*. The amount of solute in a saturated solution defines

the *solubility* of the solute, the extent to which a particular solute dissolves in a particular solvent.

13.3 FACTORS AFFECTING SOLUBILITY

We next consider the major factors affecting solubility. The nature of the solute and solvent determines the kinds of intermolecular forces among solute and solvent particles and strongly influences solubility. Temperature also affects solubility: Most solids are more soluble in water at higher temperatures, whereas gases are less soluble in water at higher temperatures. The solubility of gases increases with increasing pressure.

A TROPICAL BEACH. Ocean water is a complex aqueous solution of many dissolved substances with sodium chloride having the highest concentration. *Dana Edmunds/PacificStock.com*

13.4 EXPRESSING SOLUTION CONCENTRATION

We examine several common ways of expressing concentration, including *mole fraction*, *molarity*, and *molality*.

13.5 COLLIGATIVE PROPERTIES

We observe that some physical properties of solutions depend only on concentration and not on the identity of the solute. These *colligative properties* include the extent to which the solute lowers the vapor pressure, increases the boiling point, and decreases the

freezing point of the solvent. The *osmotic pressure* of a solution is also a colligative property.

13.6 COLLOIDS

We close the chapter by investigating *colloids*, mixtures that are not true solutions but consist of a solute-like phase (the dispersed phase) and a solvent-like phase (the dispersion medium). The dispersed phase consists of particles larger than typical molecular sizes.

PROPERTIES OF SOLUTIONS

IN CHAPTERS 10, 11, AND 12, we explored the properties of gases, liquids, and solids. Most of the discussion focused on pure substances. However, the matter that we encounter in our daily lives, such as air, seawater, and sand, is usually composed of mixtures. In this chapter we examine homogeneous mixtures.

As we noted in earlier chapters, homogeneous mixtures are called *solutions*.

∞ (Sections 1.2 and 4.1)

When we think of solutions, we usually think of liquids, such as a solution of a salt in water, like the seawater shown in this chapter's opening photograph. Solutions, however, can also be solids or gases. For example, sterling silver is a homogeneous mixture of about 7% copper in silver and so is a solid solution. The air we breathe is a homogeneous mixture of several gases, making air a gaseous solution. Because liquid solutions are the most common, however, we focus our attention on them in this chapter.

Each substance in a solution is called a *component* of the solution. As we saw in Chapter 4, the *solvent* is normally the component present in the greatest amount, and all the other components are called *solutes*. In this chapter we compare the physical properties of solutions with the properties of the components in their pure form. We will be particularly concerned with *aqueous solutions*, which contain water as the solvent and either a gas, liquid, or solid as a solute.

13.1 THE SOLUTION PROCESS

A solution is formed when one substance disperses uniformly throughout another. The ability of substances to form solutions depends on two factors: (1) the natural tendency of substances to mix and spread into larger volumes when not restrained in some way and (2) the types of intermolecular interactions involved in the solution process.

The Natural Tendency toward Mixing

Suppose we have $O_2(g)$ and $Ar(g)$ separated by a barrier, as in ▼ FIGURE 13.1. If the barrier is removed, the gases mix to form a solution. The molecules experience very little in the way of intermolecular interactions and behave like ideal gas particles. As a result, their molecular motion causes them to spread through the larger volume, and a gaseous solution is formed.

The mixing of gases is a *spontaneous* process, meaning it occurs of its own accord without any input of energy from outside the system. The extent of spreading of the molecules and their associated kinetic energies is related to a thermodynamic quantity called *entropy*. We will examine spontaneous processes and entropy in Chapter 19. For our discussion of solutions, it is sufficient to merely recognize that the mixing that occurs when solutions form is associated with an entropy increase. Furthermore, it is the balance of the tendencies of systems to increase their entropy and decrease their energy (or enthalpy) that determines whether a process is spontaneous. Thus, the *formation of solutions is favored by the increase in entropy that accompanies mixing*.

When molecules of different types are brought together, mixing occurs spontaneously unless the molecules are restrained either by sufficiently strong intermolecular forces or by physical barriers. Thus, gases spontaneously mix unless restrained by their containers because with gases intermolecular forces are too weak to restrain the molecules. However, when the solvent or solute is a solid or liquid, intermolecular forces become important in determining whether or not a solution forms. For example, although ionic bonds hold sodium and chloride ions together in solid sodium chloride (Section 8.2), the solid dissolves in water because of the compensating strength of the attractive forces between the ions and water molecules. Sodium chloride does not dissolve in gasoline, however, because the intermolecular forces between the ions and the gasoline molecules are too weak.

▲ GIVE IT SOME THOUGHT

Which two thermodynamic quantities determine whether or not a process is spontaneous?

The Effect of Intermolecular Forces on Solution Formation

Any of the various intermolecular forces discussed in Chapter 11 can operate between solute and solvent particles in a solution. These forces are summarized in ► FIGURE 13.2. Dispersion forces, for example, dominate when one nonpolar substance, such as C_7H_{16} , dissolves in another, such as C_5H_{12} , and ion–dipole forces dominate in solutions of ionic substances in water.

► FIGURE 13.1 Spontaneous mixing of two gases to form a homogeneous mixture (solution).

GO FIGURE

Why does the oxygen atom in H_2O point toward Na^+ in the ion–dipole interaction?

▲ FIGURE 13.2 Intermolecular interactions involved in solutions.

Three kinds of intermolecular interactions are involved in solution formation:

1. *Solute–solute* interactions between solute particles must be overcome in order to disperse the solute particles through the solvent.
2. *Solvent–solvent* interactions between solvent particles must be overcome to make room for the solute particles in the solvent.
3. *Solvent–solute* interactions between solvent and solute particles occur as the particles mix.

The extent to which one substance is able to dissolve in another depends on the relative magnitudes of these three types of interactions. Solutions form when the magnitudes of the solvent–solute interactions are either comparable to or greater than the solute–solute and solvent–solvent interactions. For example, heptane (C_7H_{16}) and pentane (C_5H_{12}) dissolve in each other in all proportions. For this discussion, let's arbitrarily call heptane the solvent and pentane the solute. Both substances are nonpolar, and the magnitudes of the solvent–solute interactions (attractive dispersion forces) are comparable to the solute–solute and the solvent–solvent interactions. Thus, no forces impede mixing, and the tendency to mix (increase entropy) causes the solution to form spontaneously.

Solid NaCl dissolves readily in water because the attractive solvent–solute interactions between the polar H_2O molecules and the ions are strong enough to overcome the attractive solute–solute interactions between ions in the $\text{NaCl}(s)$ and the attractive solvent–solvent interactions between H_2O molecules. When NaCl is added to water (► FIGURE 13.3), the water molecules orient themselves on the surface of the NaCl crystals with the positive end of the water dipole oriented toward Cl^- ions and the negative end oriented toward Na^+ ions. These ion–dipole attractions are strong enough to pull the surface ions away from the solid, thus overcoming the solute–solute interactions. In order for the solid to dissolve, some solvent–solvent interactions must also be overcome to create room for the ions to “fit” among all the water molecules.

Once separated from the solid, the Na^+ and Cl^- ions are surrounded by water molecules. Interactions such as this between solute and solvent molecules are known as **solvation**. When the solvent is water, the interactions are referred to as **hydration**.

GIVE IT SOME THOUGHT

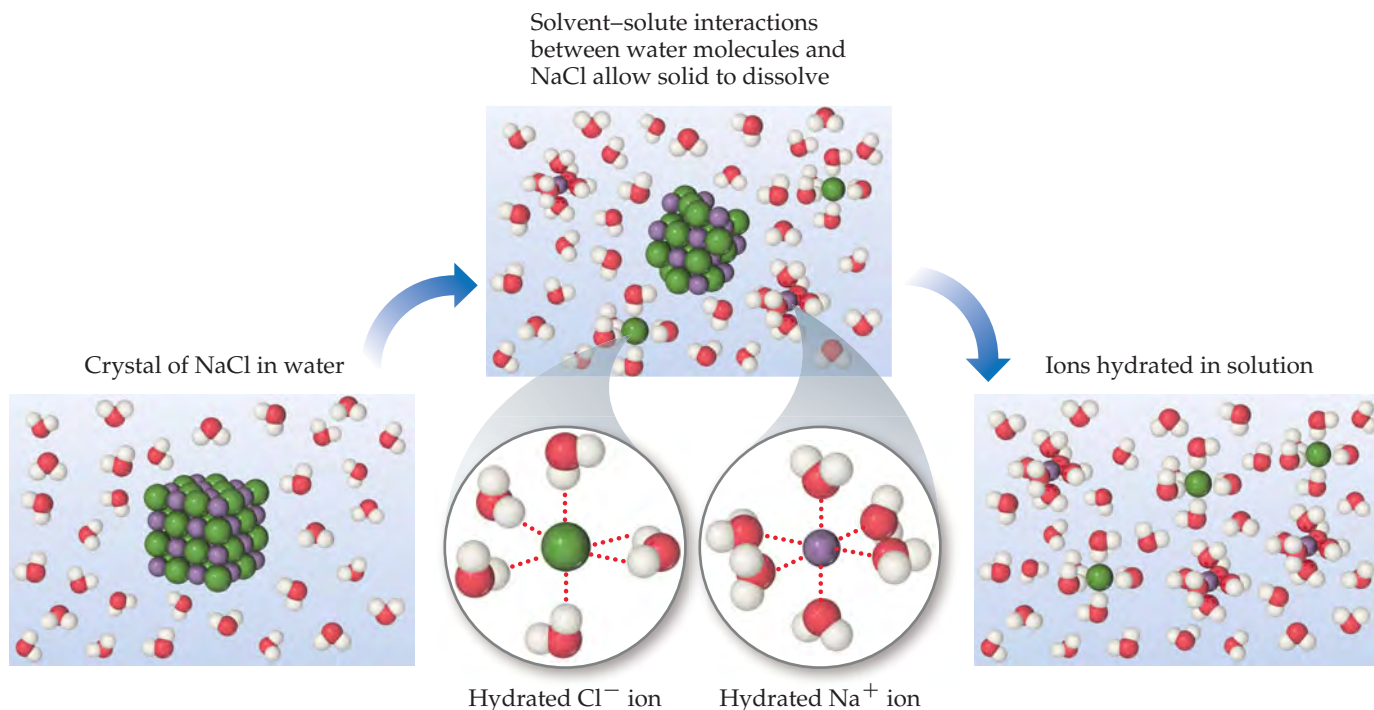

Why doesn't NaCl dissolve in nonpolar solvents such as hexane, C_6H_{14} ?

Energetics of Solution Formation

Solution processes are typically accompanied by changes in enthalpy. For example, when NaCl dissolves in water, the process is slightly endothermic, $\Delta H_{\text{soln}} = 3.9 \text{ kJ/mol}$. We can use Hess's law to analyze how the solute–solute, solvent–solvent, and solute–solvent interactions influence the enthalpy of solution. ∞ (Section 5.6)

GO FIGURE

How does the orientation of H_2O molecules around Na^+ differ from that around Cl^- ?

▲ FIGURE 13.3 Dissolution of an ionic solid in water.

We can consider the solution process as having three components, each with an associated enthalpy change: Solute particles separate from one another (ΔH_{solute}), solvent particles separate from one another ($\Delta H_{\text{solvent}}$), and solute and solvent particles mix (ΔH_{mix}). The overall enthalpy change, ΔH_{soln} , is

$$\Delta H_{\text{soln}} = \Delta H_{\text{solute}} + \Delta H_{\text{solvent}} + \Delta H_{\text{mix}} \quad [13.1]$$

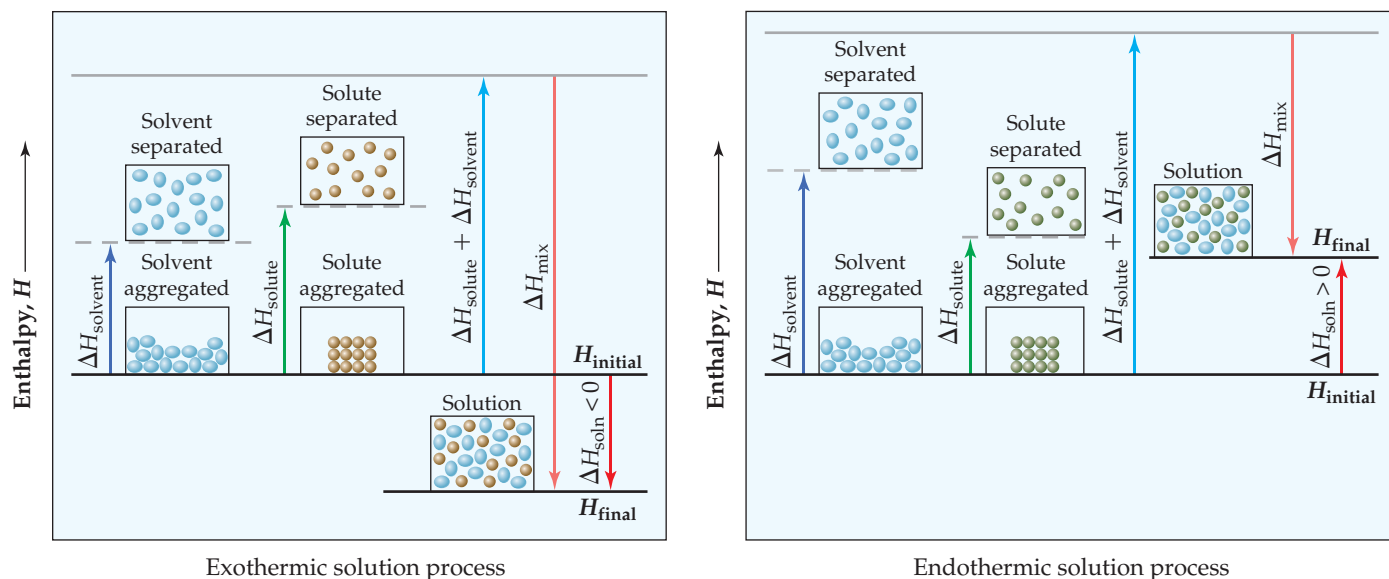

Separation of the solute particles from one another always requires an input of energy to overcome their attractive interactions. The process is therefore endothermic ($\Delta H_{\text{solute}} > 0$). Likewise, separation of solvent molecules to accommodate the solute also always requires energy ($\Delta H_{\text{solvent}} > 0$). The third component, which arises from the attractive interactions between solute particles and solvent particles, is always exothermic ($\Delta H_{\text{mix}} < 0$).

As shown in ► **FIGURE 13.4**, the three enthalpy terms in Equation 13.1 can be added together to give either a negative or a positive sum. Thus, the formation of a solution can be either exothermic or endothermic. For example, when magnesium sulfate (MgSO_4) is added to water, the solution process is exothermic: $\Delta H_{\text{soln}} = -91.2 \text{ kJ/mol}$. In contrast, the dissolution of ammonium nitrate (NH_4NO_3) is endothermic: $\Delta H_{\text{soln}} = 26.4 \text{ kJ/mol}$. These particular salts are the main components in the instant heat packs and ice packs used to treat athletic injuries (► **FIGURE 13.5**). The packs consist of a pouch of water and the solid salt sealed off from the water— $\text{MgSO}_4(s)$ for hot packs and $\text{NH}_4\text{NO}_3(s)$ for cold packs. When the pack is squeezed, the seal separating the solid from the water is broken and a solution forms, either increasing or decreasing the temperature.

The enthalpy change for a process can provide insight into the extent to which the process occurs. ∞ (Section 5.4) Exothermic processes tend to proceed spontaneously. On the other hand, if ΔH_{soln} is too endothermic, the solute might not dissolve to any

GO FIGURE

How does the magnitude of ΔH_{mix} compare with the magnitude of $\Delta H_{\text{solute}} + \Delta H_{\text{solvent}}$ for exothermic solution processes?

▲ FIGURE 13.4 Enthalpy changes accompanying the solution process.

significant extent in the chosen solvent. Thus, for solutions to form, the solvent–solute interaction must be strong enough to make ΔH_{mix} comparable in magnitude to $\Delta H_{\text{solute}} + \Delta H_{\text{solvent}}$. This fact further explains why ionic solutes do not dissolve in nonpolar solvents. The nonpolar solvent molecules experience only weak attractive interactions with the ions, and these interactions do not compensate for the energies required to separate the ions from one another.

By similar reasoning, a polar liquid solute, such as water, does not dissolve in a nonpolar liquid solvent, such as octane (C_8H_{18}). The water molecules experience strong hydrogen-bonding interactions with one another. ∞ (Section 11.2) These attractive forces must be overcome in order to disperse the water molecules throughout the octane solvent. The energy required to separate the H_2O molecules from one another is not recovered in the form of attractive interactions between the H_2O and C_8H_{18} molecules.

GIVE IT SOME THOUGHT

- Label the following processes as exothermic or endothermic:
- breaking solvent–solvent interactions to form separated particles;
 - forming solvent–solute interactions from separated particles.

Solution Formation and Chemical Reactions

In discussing solutions, we must be careful to distinguish the physical process of solution formation from chemical reactions that lead to a solution. For example, nickel metal dissolves on contact with hydrochloric acid solution because the following reaction occurs:

In this instance the resultant solution is not that of the Ni metal but rather its salt NiCl_2 . If the solution is evaporated to dryness, $\text{NiCl}_2 \cdot 6 \text{H}_2\text{O}(s)$ is recovered (► FIGURE 13.6). When $\text{NaCl}(s)$ is dissolved in water, on the other hand, no chemical reaction occurs. If the solution is evaporated to dryness, NaCl is recovered. Our focus throughout this chapter is on solutions from which the solute can be recovered unchanged from the solution.

▲ FIGURE 13.5 Ammonium nitrate instant ice pack.

Nickel metal and hydrochloric acid

Nickel reacts with hydrochloric acid, forming $\text{NiCl}_2(\text{aq})$ and $\text{H}_2(\text{g})$. The solution is of NiCl_2 , not Ni metal $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}(\text{s})$ remains when solvent evaporated

▲ **FIGURE 13.6** The reaction between nickel metal and hydrochloric acid is *not* a simple dissolution.

A CLOSER LOOK

HYDRATES

Frequently, hydrated ions remain in crystalline salts that are obtained by evaporation of water from aqueous solutions. Common examples include $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ [iron(III) chloride hexahydrate] and $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ [copper(II) sulfate pentahydrate]. The $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ consists of $\text{Fe}(\text{H}_2\text{O})_6^{3+}$ and Cl^- ions; the $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ consists of $\text{Cu}(\text{H}_2\text{O})_4^{2+}$ and $\text{SO}_4(\text{H}_2\text{O})_2^{2-}$ ions. Water molecules can also occur in positions in the crystal lattice that are not specifically associated with either a cation or an anion. $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$ (barium chloride dihydrate) is an example. Compounds such as $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$, $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$, and $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$, which contain a salt and water combined in definite proportions, are known as *hydrates*. The water associated with them is called *water of hydration*. ► **FIGURE 13.7** shows a hydrate and the corresponding anhydrous (water-free) substance.

▲ **FIGURE 13.7** A hydrate and its anhydrous salt. The anhydrous salt is the white substance, which turns blue upon addition of water.

13.2 SATURATED SOLUTIONS AND SOLUBILITY

As a solid solute begins to dissolve in a solvent, the concentration of solute particles in solution increases, increasing the chances that some solute particles will collide with the surface of the solid and reattach. This process, which is the opposite of the solution process, is called **crystallization**. Thus, two opposing processes occur in a solution in contact with undissolved solute. This situation is represented in a chemical equation by two half arrows:

GO FIGURE

What two processes are represented in this figure, and what are their relative rates at equilibrium?

▲ FIGURE 13.8 Dynamic equilibrium in a saturated solution with excess ionic solute.

When the rates of these opposing processes become equal, a *dynamic equilibrium* is established and there is no further increase in the amount of solute in solution. (▲ FIGURE 13.8)

A solution that is in equilibrium with undissolved solute is **saturated**. Additional solute will not dissolve if added to a saturated solution. The amount of solute needed to form a saturated solution in a given quantity of solvent is known as the **solubility** of that solute. That is, *the solubility of a given solute in a given solvent is the maximum amount of the solute that can dissolve in a given amount of the solvent at a specified temperature, given that excess solute is present*. For example, the solubility of NaCl in water at 0 °C is 35.7 g per 100 mL of water. This is the maximum amount of NaCl that can be dissolved in water to give a stable equilibrium solution at that temperature.

If we dissolve less solute than the amount needed to form a saturated solution, the solution is **unsaturated**. Thus, a solution containing 10.0 g of NaCl per 100 mL of water at 0 °C is unsaturated because it has the capacity to dissolve more solute.

Under suitable conditions it is possible to form solutions that contain a greater amount of solute than needed to form a saturated solution. Such solutions are **supersaturated**. For example, when a saturated solution of sodium acetate is made at a high temperature and then slowly cooled, all of the solute may remain dissolved even though its solubility decreases as the temperature decreases. Because the solute in a supersaturated solution is present in a concentration higher than the equilibrium concentration, supersaturated solutions are unstable. For crystallization to occur, however, the solute particles must arrange themselves properly to form crystals. The addition of a small crystal of the solute (a seed crystal) provides a template for crystallization of the excess solute, leading to a saturated solution in contact with excess solid (► FIGURE 13.9).

▲ GIVE IT SOME THOUGHT

What happens if solute is added to a saturated solution?

GO FIGURE

What is the evidence that the solution in the left photograph is supersaturated?

▲ FIGURE 13.9 Precipitation from a supersaturated sodium acetate solution. The solution on the left was formed by dissolving about 170 g of the salt in 100 mL of water at 100 °C and then slowly cooling it to 20 °C. Because the solubility of sodium acetate in water at 20 °C is 46 g per 100 mL of water, the solution is supersaturated. Addition of a sodium acetate crystal causes the excess solute to crystallize from solution.

13.3 FACTORS AFFECTING SOLUBILITY

The extent to which one substance dissolves in another depends on the nature of both substances. ∞ (Section 13.1) It also depends on temperature and, at least for gases, on pressure.

Solute–Solvent Interactions

The natural tendency of substances to mix and the various interactions among solute and solvent particles are all involved in determining solubilities. Nevertheless, insight into variations in solubility can often be gained by simply focusing on the interaction between the solute and solvent. The data in ◀ TABLE 13.1 show, for example, that the solubilities of various simple gases in water increase with increasing molecular mass or increasing polarity. The attractive forces between the gas molecules and solvent molecules are mainly dispersion forces, which increase with increasing size and molecular mass. ∞ (Section 11.2) Thus, the data indicate that the solubilities of gases in water increase as the attraction between solute (gas) and solvent (water) increases. In general, when other factors are comparable, *the stronger the attractions between solute and solvent molecules, the greater the solubility of the solute in that solvent.*

Because of favorable dipole–dipole attractions between solvent molecules and solute molecules, *polar liquids tend to dissolve in polar solvents.* Water is both polar and able to form hydrogen bonds. ∞ (Section 11.2) Thus, polar molecules, especially those that can form hydrogen bonds with water molecules, tend to be soluble in water. For example, acetone, a polar molecule with the structural formula shown in the margin, mixes in all proportions with water. Acetone has a strongly polar C=O bond and pairs of nonbonding electrons on the O atom that can form hydrogen bonds with water.

TABLE 13.1 • Solubilities of Gases in Water at 20 °C, with 1 atm Gas Pressure

Gas	Solubility (<i>M</i>)
N ₂	0.69×10^{-3}
CO	1.04×10^{-3}
O ₂	1.38×10^{-3}
Ar	1.50×10^{-3}
Kr	2.79×10^{-3}

Acetone

Pairs of liquids that mix in all proportions, such as acetone and water, are **miscible**, whereas those that do not dissolve in one another are **immiscible**. Gasoline, which is a mixture of hydrocarbons, is immiscible with water. Hydrocarbons are nonpolar substances because of several factors: The C—C bonds are nonpolar, the C—H bonds are nearly nonpolar, and the molecules are symmetrical enough to cancel much of the weak C—H bond dipoles. The attraction between the polar water molecules and the nonpolar hydrocarbon molecules is not sufficiently strong to allow the formation of a solution. *Nonpolar liquids tend to be insoluble in polar liquids*, as ► **FIGURE 13.10** shows for hexane (C₆H₁₄) and water.

Many organic compounds have polar groups attached to a nonpolar framework of carbon and hydrogen atoms. For example, the series of organic compounds in ▼ **TABLE 13.2** all contain the polar OH group. Organic compounds with this molecular feature are called *alcohols*. The O—H bond is able to form hydrogen bonds. For example, ethanol (CH₃CH₂OH) molecules can form hydrogen bonds with water molecules as well as with each other (▼ **FIGURE 13.11**). As a result, the solute–solute, solvent–solvent, and solute–solvent forces are not greatly different in a mixture of CH₃CH₂OH and H₂O. No major change occurs in the environments of the molecules as they are mixed. Therefore, the increased entropy when the components mix plays a significant role in solution formation, and ethanol is completely miscible with water.

▲ **FIGURE 13.11** Hydrogen bonding involving OH groups.

Notice in Table 13.2 that the number of carbon atoms in an alcohol affects its solubility in water. As this number increases, the polar OH group becomes an ever smaller part of the molecule, and the molecule behaves more like a hydrocarbon. The solubility of the alcohol in water decreases correspondingly. On the other hand, the solubility of alcohols in a nonpolar solvent like hexane (C₆H₁₄) increases as the nonpolar hydrocarbon chain lengthens.

One way to enhance the solubility of a substance in water is to increase the number of polar groups the substance contains. For example, increasing the number of OH groups in a solute increases the extent of hydrogen bonding between that solute and water, thereby increasing solubility. Glucose (C₆H₁₂O₆, ► **FIGURE 13.12**) has five OH groups on a six-carbon framework, which makes the molecule very soluble in water (83 g dissolves in 100 mL of water at 17.5 °C).

TABLE 13.2 • Solubilities of Some Alcohols in Water and in Hexane*

Alcohol	Solubility in H ₂ O	Solubility in C ₆ H ₁₄
CH ₃ OH (methanol)	∞	0.12
CH ₃ CH ₂ OH (ethanol)	∞	∞
CH ₃ CH ₂ CH ₂ OH (propanol)	∞	∞
CH ₃ CH ₂ CH ₂ CH ₂ OH (butanol)	0.11	∞
CH ₃ CH ₂ CH ₂ CH ₂ CH ₂ OH (pentanol)	0.030	∞
CH ₃ CH ₂ CH ₂ CH ₂ CH ₂ CH ₂ OH (hexanol)	0.0058	∞

*Expressed in mol alcohol/100 g solvent at 20 °C. The infinity symbol (∞) indicates that the alcohol is completely miscible with the solvent.

▲ **FIGURE 13.10** Hexane is immiscible with water. Hexane is the top layer because it is less dense than water.

Cyclohexane, C₆H₁₂, which has no polar OH groups, is essentially insoluble in water

OH groups enhance the aqueous solubility because of their ability to hydrogen bond with H₂O.

Glucose, C₆H₁₂O₆, has five OH groups and is highly soluble in water

CHEMISTRY AND LIFE

FAT-SOLUBLE AND WATER-SOLUBLE VITAMINS

Vitamins have unique chemical structures that affect their solubilities in different parts of the human body. Vitamin C and the B vitamins are soluble in water, for example, whereas vitamins A, D, E, and K are soluble in nonpolar solvents and in fatty tissue (which is nonpolar). Because of their water solubility, vitamins B and C are not stored to any appreciable extent in the body, and so foods containing these vitamins should be included in the daily diet. In contrast, the fat-soluble vitamins are stored in sufficient quantities to keep vitamin-

deficiency diseases from appearing even after a person has subsisted for a long period on a vitamin-deficient diet.

That some vitamins are soluble in water and others are not can be explained in terms of their structures. Notice in **FIGURE 13.13** that vitamin A (retinol) is an alcohol with a very long carbon chain. Because the OH group is such a small part of the molecule, the molecule resembles the long-chain alcohols listed in Table 13.2. This vitamin is nearly nonpolar. In contrast, the vitamin C molecule is smaller and has several OH groups that can form hydrogen bonds with water. In this regard, it is somewhat like glucose.

RELATED EXERCISES: 13.7, 13.48

◀ **FIGURE 13.13** Vitamins A and C.

Over the years, examination of different solvent–solute combinations has led to an important generalization: *Substances with similar intermolecular attractive forces tend to be soluble in one another.* This generalization is often simply stated as “like dissolves like.” Nonpolar substances are more likely to be soluble in nonpolar solvents; ionic and polar solutes are more likely to be soluble in polar solvents. Network solids such as diamond and quartz are not soluble in either polar or nonpolar solvents because of the strong bonding forces within the solid.

▲ **GIVE IT SOME THOUGHT**

Suppose the hydrogens on the OH groups in glucose (Figure 13.12) were replaced with methyl groups, CH₃. Would you expect the water solubility of the resulting molecule to be higher than, lower than, or about the same as the solubility of glucose?

SAMPLE EXERCISE 13.1 Predicting Solubility Patterns

Predict whether each of the following substances is more likely to dissolve in the nonpolar solvent carbon tetrachloride (CCl₄) or in water: C₇H₁₆, Na₂SO₄, HCl, and I₂.

SOLUTION

Analyze We are given two solvents, one that is nonpolar (CCl_4) and the other that is polar (H_2O), and asked to determine which will be the better solvent for each solute listed.

Plan By examining the formulas of the solutes, we can predict whether they are ionic or molecular. For those that are molecular, we can predict whether they are polar or nonpolar. We can then apply the idea that the nonpolar solvent will be better for the nonpolar solutes, whereas the polar solvent will be better for the ionic and polar solutes.

Solve C_7H_{16} is a hydrocarbon, so it is molecular and nonpolar. Na_2SO_4 , a compound containing a metal and nonmetals, is ionic. HCl , a diatomic molecule containing two nonmetals that differ in electronegativity, is polar. I_2 , a diatomic molecule with atoms of equal electronegativity, is nonpolar. We would therefore predict that C_7H_{16} and I_2 (the nonpolar solutes) would be more soluble in the nonpolar CCl_4 than in polar H_2O , whereas water would be the better solvent for Na_2SO_4 and HCl (the ionic and polar covalent solutes).

PRACTICE EXERCISE

Arrange the following substances in order of increasing solubility in water:

Answer: $\text{C}_5\text{H}_{12} < \text{C}_5\text{H}_{11}\text{Cl} < \text{C}_5\text{H}_{11}\text{OH} < \text{C}_5\text{H}_{10}(\text{OH})_2$ (in order of increasing polarity and hydrogen-bonding ability)

Pressure Effects

The solubilities of solids and liquids are not appreciably affected by pressure, whereas *the solubility of a gas in any solvent is increased as the partial pressure of the gas above the solvent increases*. We can understand the effect of pressure on gas solubility by considering ▼ **FIGURE 13.14**, which shows carbon dioxide gas distributed between the gas and

GO FIGURE

If the partial pressure of a gas over a solution is doubled, how has the concentration of gas in the solution changed after equilibrium is restored?

▲ **FIGURE 13.14** Effect of pressure on gas solubility.

GO FIGURE

How do the slopes of the lines vary with the molecular weight of the gas? Explain the trend.

▲ FIGURE 13.15 The solubility of a gas in water is directly proportional to the partial pressure of the gas. The solubilities are in millimoles per liter of solution.

▲ FIGURE 13.16 Gas solubility decreases as pressure decreases. CO₂ bubbles out of solution when a carbonated beverage is opened because the CO₂ partial pressure above the solution is reduced.

solution phases. When equilibrium is established, the rate at which gas molecules enter the solution equals the rate at which solute molecules escape from the solution to enter the gas phase. The equal number of up and down arrows in the left container in Figure 13.14 represent these opposing processes.

Now suppose we exert greater pressure on the piston and compress the gas above the solution, as shown in the middle container in Figure 13.14. If we reduce the gas volume to half its original value, the pressure of the gas increases to about twice its original value. As a result of this pressure increase, the rate at which gas molecules strike the liquid surface and enter the solution phase increases. Thus, the solubility of the gas in the solution increases until equilibrium is again established; that is, solubility increases until the rate at which gas molecules enter the solution equals the rate at which they escape from the solution. Thus, *the solubility of a gas in a liquid solvent increases in direct proportion to the partial pressure of the gas above the solution* (◀ FIGURE 13.15).

The relationship between pressure and gas solubility is expressed by **Henry's law**:

$$S_g = kP_g \quad [13.4]$$

Here, S_g is the solubility of the gas in the solvent (usually expressed as molarity), P_g is the partial pressure of the gas over the solution, and k is a proportionality constant known as the *Henry's law constant*. The value of this constant depends on the solute, solvent, and temperature. As an example, the solubility of N₂ gas in water at 25 °C and 0.78 atm pressure is $4.75 \times 10^{-4} M$. The Henry's law constant for N₂ in 25 °C water is thus $(4.75 \times 10^{-4} \text{ mol/L})/0.78 \text{ atm} = 6.1 \times 10^{-4} \text{ mol/L}\cdot\text{atm}$. If the partial pressure of N₂ is doubled, Henry's law predicts that the solubility in water at 25 °C also doubles to $9.50 \times 10^{-4} M$.

Bottlers use the effect of pressure on solubility in producing carbonated beverages, which are bottled under a carbon dioxide pressure greater than 1 atm. When the bottles are opened to the air, the partial pressure of CO₂ above the solution decreases. Hence, the solubility of CO₂ decreases, and CO₂(g) escapes from the solution as bubbles (◀ FIGURE 13.16).

SAMPLE EXERCISE 13.2 A Henry's Law Calculation

Calculate the concentration of CO₂ in a soft drink that is bottled with a partial pressure of CO₂ of 4.0 atm over the liquid at 25 °C. The Henry's law constant for CO₂ in water at this temperature is $3.4 \times 10^{-2} \text{ mol/L}\cdot\text{atm}$.

SOLUTION

Analyze We are given the partial pressure of CO₂, P_{CO_2} , and the Henry's law constant, k , and asked to calculate the concentration of CO₂ in the solution.

Plan With the information given, we can use Henry's law, Equation 13.4, to calculate the solubility, S_{CO_2} .

Solve $S_{\text{CO}_2} = kP_{\text{CO}_2} = (3.4 \times 10^{-2} \text{ mol/L}\cdot\text{atm})(4.0 \text{ atm}) = 0.14 \text{ mol/L} = 0.14 M$

Check The units are correct for solubility, and the answer has two significant figures consistent with both the partial pressure of CO₂ and the value of Henry's constant.

PRACTICE EXERCISE

Calculate the concentration of CO₂ in a soft drink after the bottle is opened and equilibrates at 25 °C under a CO₂ partial pressure of $3.0 \times 10^{-4} \text{ atm}$.

Answer: $1.0 \times 10^{-5} M$

CHEMISTRY AND LIFE

BLOOD GASES AND DEEP-SEA DIVING

Because gas solubility increases with increasing pressure, divers who breathe compressed air (► FIGURE 13.17) must be concerned about the solubility of gases in their blood. Although the gases are not very soluble at sea level, their solubilities can be appreciable at deep levels where their partial pressures are greater. Thus, divers must ascend slowly to prevent dissolved gases from being released rapidly from solution and forming bubbles in the blood and other fluids in the body. These bubbles affect nerve impulses and cause decompression sickness, or “the bends,” which is a painful and potentially fatal condition. Nitrogen is the main problem because it has the highest partial pressure in air and because it can be removed from the body only through the respiratory system. Oxygen, in contrast, is consumed in metabolism.

Deep-sea divers sometimes substitute helium for nitrogen in the air they breathe because helium has a much lower solubility in biological fluids than N_2 . For example, divers working at a depth of 100 ft experience a pressure of about 4 atm. At this pressure a mixture of 95% helium and 5% oxygen gives an oxygen partial pressure of about 0.2

▲ FIGURE 13.17 Gas solubility increases as pressure increases. Divers who use compressed gases must be concerned about the solubility of the gases in their blood.

atm, which is the partial pressure of oxygen in normal air at 1 atm. If the oxygen partial pressure becomes too great, the urge to breathe is reduced, CO_2 is not removed from the body, and CO_2 poisoning occurs. At excessive concentrations in the body, carbon dioxide acts as a neurotoxin, interfering with nerve conduction and transmission.

RELATED EXERCISES: 13.59, 13.60, 13.107

Temperature Effects

The solubility of most solid solutes in water increases as the solution temperature increases, as ▼ FIGURE 13.18 shows. There are exceptions to this rule, however, as seen for $Ce_2(SO_4)_3$, whose solubility curve slopes downward with increasing temperature.

In contrast to solid solutes, the solubility of gases in water decreases with increasing temperature (▼ FIGURE 13.19). If a glass of cold tap water is warmed, you can see bubbles on the inside of the glass because some of the dissolved air comes out of solution.

GO FIGURE

How does the solubility of KCl at 80 °C compare with that of NaCl at the same temperature?

▲ FIGURE 13.18 Solubilities of some ionic compounds in water as a function of temperature.

GO FIGURE

Where would you expect N_2 to fit on this graph?

▲ FIGURE 13.19 Solubilities of four gases in water as a function of temperature. The solubilities are in millimoles per liter of solution, for a constant total pressure of 1 atm in the gas phase.

Similarly, as carbonated beverages are allowed to warm, the solubility of CO_2 decreases, and $\text{CO}_2(\text{g})$ escapes from the solution.

The decreased solubility of O_2 in water as temperature increases is one of the effects of *thermal pollution* of lakes and streams. The effect is particularly serious in deep lakes because warm water is less dense than cold water. Warm water therefore tends to remain on top of cold water, at the surface. This situation impedes the dissolving of oxygen in the deeper layers, thus stifling the respiration of all aquatic life needing oxygen. Fish may suffocate and die under these conditions.

GIVE IT SOME THOUGHT

Why do bubbles form on the inside wall of a cooking pot when water is heated on the stove, even though the water temperature is well below the boiling point of water?

13.4 EXPRESSING SOLUTION CONCENTRATION

The concentration of a solution can be expressed either qualitatively or quantitatively. The terms *dilute* and *concentrated* are used to describe a solution qualitatively. A solution with a relatively small concentration of solute is said to be dilute; one with a large concentration is said to be concentrated. Chemists use various ways to express concentration quantitatively, and we examine several of these next.

Mass Percentage, ppm, and ppb

One of the simplest quantitative expressions of concentration is the **mass percentage** of a component in a solution, given by

$$\text{Mass \% of component} = \frac{\text{mass of component in soln}}{\text{total mass of soln}} \times 100 \quad [13.5]$$

Because *percent* means “per hundred,” a solution of hydrochloric acid that is 36% HCl by mass contains 36 g of HCl for each 100 g of solution.

We often express the concentration of very dilute solutions in **parts per million (ppm)** or **parts per billion (ppb)**. These quantities are similar to mass percentage but use 10^6 (a million) or 10^9 (a billion), respectively, in place of 100 as a multiplier for the ratio of the mass of solute to the mass of solution. Thus, parts per million is defined as

$$\text{ppm of component} = \frac{\text{mass of component in soln}}{\text{total mass of soln}} \times 10^6 \quad [13.6]$$

A solution whose solute concentration is 1 ppm contains 1 g of solute for each million (10^6) grams of solution or, equivalently, 1 mg of solute per kilogram of solution. Because the density of water is 1 g/mL, 1 kg of a dilute aqueous solution has a volume very close to 1 L. Thus, 1 ppm also corresponds to 1 mg of solute per liter of aqueous solution.

The acceptable maximum concentrations of toxic or carcinogenic substances in the environment are often expressed in ppm or ppb. For example, the maximum allowable concentration of arsenic in drinking water in the United States is 0.010 ppm; that is, 0.010 mg of arsenic per liter of water. This concentration corresponds to 10 ppb.

GIVE IT SOME THOUGHT

A solution of SO_2 in water contains 0.00023 g of SO_2 per liter of solution. What is the concentration of SO_2 in ppm? In ppb?

SAMPLE EXERCISE 13.3 Calculation of Mass-Related Concentrations

(a) A solution is made by dissolving 13.5 g of glucose ($\text{C}_6\text{H}_{12}\text{O}_6$) in 0.100 kg of water. What is the mass percentage of solute in this solution? (b) A 2.5-g sample of groundwater was found to contain 5.4 μg of Zn^{2+} . What is the concentration of Zn^{2+} in parts per million?

SOLUTION

(a) Analyze We are given the number of grams of solute (13.5 g) and the number of grams of solvent (0.100 kg = 100 g). From this we must calculate the mass percentage of solute.

Plan We can calculate the mass percentage by using Equation 13.5. The mass of the solution is the sum of the mass of solute (glucose) and the mass of solvent (water).

$$\text{Solve} \quad \text{Mass \% of glucose} = \frac{\text{mass glucose}}{\text{mass soln}} \times 100 = \frac{13.5 \text{ g}}{13.5 \text{ g} + 100 \text{ g}} \times 100 = 11.9\%$$

Comment The mass percentage of water in this solution is $(100 - 11.9)\% = 88.1\%$.

(b) Analyze In this case we are given the number of micrograms of solute. Because $1 \mu\text{g}$ is $1 \times 10^{-6} \text{ g}$, $5.4 \mu\text{g} = 5.4 \times 10^{-6} \text{ g}$.

Plan We calculate the parts per million using Equation 13.6.

$$\text{Solve} \quad \text{ppm} = \frac{\text{mass of solute}}{\text{mass of soln}} \times 10^6 = \frac{5.4 \times 10^{-6} \text{ g}}{2.5 \text{ g}} \times 10^6 = 2.2 \text{ ppm}$$

PRACTICE EXERCISE

(a) Calculate the mass percentage of NaCl in a solution containing 1.50 g of NaCl in 50.0 g of water. (b) A commercial bleaching solution contains 3.62 mass % sodium hypochlorite, NaOCl. What is the mass of NaOCl in a bottle containing 2.50 kg of bleaching solution?

Answers: (a) 2.91%, (b) 90.5 g of NaOCl

Mole Fraction, Molarity, and Molality

Concentration expressions are often based on the number of moles of one or more components of the solution. Recall from Section 10.6 that the *mole fraction* of a component of a solution is given by

$$\text{Mole fraction of component} = \frac{\text{moles of component}}{\text{total moles of all components}} \quad [13.7]$$

The symbol X is commonly used for mole fraction, with a subscript to indicate the component of interest. For example, the mole fraction of HCl in a hydrochloric acid solution is represented as X_{HCl} . Thus, if a solution contains 1.00 mol of HCl (36.5 g) and 8.00 mol of water (144 g), the mole fraction of HCl is $X_{\text{HCl}} = (1.00 \text{ mol}) / (1.00 \text{ mol} + 8.00 \text{ mol}) = 0.111$. Mole fractions have no units because the units in the numerator and the denominator cancel. The sum of the mole fractions of all components of a solution must equal 1. Thus, in the aqueous HCl solution, $X_{\text{H}_2\text{O}} = 1.000 - 0.111 = 0.889$. Mole fractions are very useful when dealing with gases, as we saw in Section 10.6, but have limited use when dealing with liquid solutions.

Recall from Section 4.5 that the *molarity* (M) of a solute in a solution is defined as

$$\text{Molarity} = \frac{\text{moles of solute}}{\text{liters of soln}} \quad [13.8]$$

For example, if you dissolve 0.500 mol of Na_2CO_3 in enough water to form 0.250 L of solution, the molarity of Na_2CO_3 in the solution is $(0.500 \text{ mol}) / (0.250 \text{ L}) = 2.00 \text{ M}$. Molarity is especially useful for relating the volume of a solution to the quantity of solute contained in that volume, as we saw in our discussions of titrations. [∞ \(Section 4.6\)](#)

The **molality** of a solution, denoted m , is a concentration unit that is also based on moles of solute. Molality equals the number of moles of solute per kilogram of solvent:

$$\text{Molality} = \frac{\text{moles of solute}}{\text{kilograms of solvent}} \quad [13.9]$$

Thus, if you form a solution by mixing 0.200 mol of NaOH (8.00 g) and 0.500 kg of water (500 g), the concentration of the solution is $(0.200 \text{ mol}) / (0.500 \text{ kg}) = 0.400 \text{ m}$ (that is, 0.400 molal) in NaOH.

The definitions of molarity and molality are similar enough that they can be easily confused. Molarity depends on the *volume of solution*, whereas molality depends on the *mass of solvent*. When water is the solvent, the molality and molarity of dilute solutions are numerically about the same because 1 kg of solvent is nearly the same as 1 kg of solution, and 1 kg of the solution has a volume of about 1 L.

The molality of a given solution does not vary with temperature because masses do not vary with temperature. The molarity of the solution does change with temperature, however, because the volume of the solution expands or contracts with temperature. Thus, molality is often the concentration unit of choice when a solution is to be used over a range of temperatures.

GIVE IT SOME THOUGHT

If an aqueous solution is very dilute, will its molality be greater than its molarity, nearly the same as its molarity, or smaller than its molarity?

SAMPLE EXERCISE 13.4 Calculation of Molality

A solution is made by dissolving 4.35 g glucose ($C_6H_{12}O_6$) in 25.0 mL of water at 25 °C. Calculate the molality of glucose in the solution. Water has a density of 1.00 g/mL.

SOLUTION

Analyze We are asked to calculate a molality. To do this, we must determine the number of moles of solute (glucose) and the number of kilograms of solvent (water).

Plan We use the molar mass of $C_6H_{12}O_6$ to convert grams to moles. We use the density of water to convert milliliters to kilograms. The molality equals the number of moles of solute divided by the number of kilograms of solvent (Equation 13.9).

Solve Use the molar mass of glucose, 180.2 g/mol, to convert grams to moles:

$$\text{Mol } C_6H_{12}O_6 = (4.35 \text{ g } C_6H_{12}O_6) \left(\frac{1 \text{ mol } C_6H_{12}O_6}{180.2 \text{ g } C_6H_{12}O_6} \right) = 0.0241 \text{ mol } C_6H_{12}O_6$$

Because water has a density of 1.00 g/mL, the mass of the solvent is

$$(25.0 \text{ mL})(1.00 \text{ g/mL}) = 25.0 \text{ g} = 0.0250 \text{ kg}$$

Finally, use Equation 13.9 to obtain the molality:

$$\text{Molality of } C_6H_{12}O_6 = \frac{0.0241 \text{ mol } C_6H_{12}O_6}{0.0250 \text{ kg } H_2O} = 0.964 \text{ } m$$

PRACTICE EXERCISE

What is the molality of a solution made by dissolving 36.5 g of naphthalene ($C_{10}H_8$) in 425 g of toluene (C_7H_8)?

Answer: 0.670 *m*

Converting Concentration Units

Sometimes the concentration of a given solution needs to be known in several concentration units. It is possible to interconvert concentration units as shown in Sample Exercise 13.5.

SAMPLE EXERCISE 13.5 Calculation of Mole Fraction and Molality

An aqueous solution of hydrochloric acid contains 36% HCl by mass. (a) Calculate the mole fraction of HCl in the solution. (b) Calculate the molality of HCl in the solution.

SOLUTION

Analyze We are asked to calculate the concentration of the solute, HCl, in two related concentration units, given only the percentage by mass of the solute in the solution.

Plan In converting concentration units based on the mass or moles of solute and solvent (mass percentage, mole fraction, and molality), it is useful to assume a certain total mass of solution. Let's assume that there is exactly 100 g of solution. Because the solution is 36% HCl, it contains 36 g of HCl and $(100 - 36) \text{ g} = 64 \text{ g}$ of H_2O . We must convert grams of solute (HCl) to moles to calculate either mole fraction or molality. We must convert grams of solvent (H_2O) to moles to calculate mole fractions and to kilograms to calculate molality.

Solve (a) To calculate the mole fraction of HCl, we convert the masses of HCl and H₂O to moles and then use Equation 13.7:

$$\text{Moles HCl} = (36 \text{ g HCl}) \left(\frac{1 \text{ mol HCl}}{36.5 \text{ g HCl}} \right) = 0.99 \text{ mol HCl}$$

$$\text{Moles H}_2\text{O} = (64 \text{ g H}_2\text{O}) \left(\frac{1 \text{ mol H}_2\text{O}}{18 \text{ g H}_2\text{O}} \right) = 3.6 \text{ mol H}_2\text{O}$$

$$X_{\text{HCl}} = \frac{\text{moles HCl}}{\text{moles H}_2\text{O} + \text{moles HCl}} = \frac{0.99}{3.6 + 0.99} = \frac{0.99}{4.6} = 0.22$$

(b) To calculate the molality of HCl in the solution, we use Equation 13.9. We calculated the number of moles of HCl in part (a), and the mass of solvent is 64 g = 0.064 kg:

$$\text{Molality of HCl} = \frac{0.99 \text{ mol HCl}}{0.064 \text{ kg H}_2\text{O}} = 15 \text{ m}$$

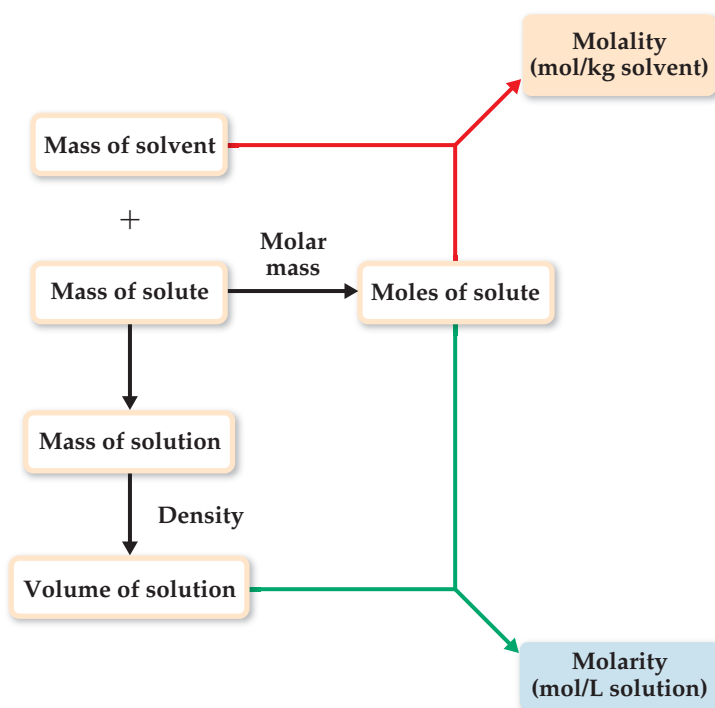

PRACTICE EXERCISE

A commercial bleach solution contains 3.62 mass % NaOCl in water. Calculate (a) the mole fraction and (b) the molality of NaOCl in the solution.

Answers: (a) 9.00×10^{-3} , (b) 0.505 m

To interconvert molality and molarity, we need to know the density of the solution.

▼ **FIGURE 13.20** outlines the calculation of the molarity and molality of a solution from the mass of solute and the mass of solvent. The mass of the solution is the sum of masses of the solvent and solute. The volume of the solution can be calculated from its mass and density.

◀ **FIGURE 13.20** Calculating molality and molarity from solute mass, solvent mass, and solution density.

SAMPLE EXERCISE 13.6 Calculation of Molarity Using the Density of the Solution

A solution with a density of 0.876 g/mL contains 5.0 g of toluene (C₇H₈) and 225 g of benzene. Calculate the molarity of the solution.

SOLUTION

Analyze Our goal is to calculate the molarity of a solution, given the masses of solute (5.0 g) and solvent (225 g) and the density of the solution (0.876 g/mL).

Plan The molarity of a solution is the number of moles of solute divided by the number of liters of solution (Equation 13.8). The number of moles of solute (C₇H₈) is calculated from the number of grams of solute and its molar mass. The volume of the solution is obtained from the mass of the solution (mass of solute + mass of solvent = 5.0 g + 225 g = 230 g) and its density.

Solve The number of moles of solute is

$$\text{Moles } \text{C}_7\text{H}_8 = (5.0 \text{ g } \text{C}_7\text{H}_8) \left(\frac{1 \text{ mol } \text{C}_7\text{H}_8}{92 \text{ g } \text{C}_7\text{H}_8} \right) = 0.054 \text{ mol}$$

The density of the solution is used to convert the mass of the solution to its volume:

$$\text{Milliliters soln} = (230 \text{ g}) \left(\frac{1 \text{ mL}}{0.876 \text{ g}} \right) = 263 \text{ mL}$$

Molarity is moles of solute per liter of solution:

$$\text{Molarity} = \left(\frac{\text{moles } \text{C}_7\text{H}_8}{\text{liter soln}} \right) = \left(\frac{0.054 \text{ mol } \text{C}_7\text{H}_8}{263 \text{ mL soln}} \right) \left(\frac{1000 \text{ mL soln}}{1 \text{ L soln}} \right) = 0.21 \text{ M}$$

Check The magnitude of our answer is reasonable. Rounding moles to 0.05 and liters to 0.25 gives a molarity of

$$(0.05 \text{ mol}) / (0.25 \text{ L}) = 0.2 \text{ M}$$

The units for our answer (mol/L) are correct, and the answer, 0.21, has two significant figures, corresponding to the number of significant figures in the mass of solute (2).

Comment Because the mass of the solvent (0.225 kg) and the volume of the solution (0.263) are similar in magnitude, the molarity and molality are also similar in magnitude:

$$(0.054 \text{ mol } \text{C}_7\text{H}_8) / (0.225 \text{ kg solvent}) = 0.24 \text{ m}$$

PRACTICE EXERCISE

A solution containing equal masses of glycerol ($\text{C}_3\text{H}_8\text{O}_3$) and water has a density of 1.10 g/mL. Calculate (a) the molality of glycerol, (b) the mole fraction of glycerol, (c) the molarity of glycerol in the solution.

Answers: (a) 10.9 m, (b) $X_{\text{C}_3\text{H}_8\text{O}_3} = 0.163$, (c) 5.97 M

13.5 COLLIGATIVE PROPERTIES

Some physical properties of solutions differ in important ways from those of the pure solvent. For example, pure water freezes at 0 °C, but aqueous solutions freeze at lower temperatures. We utilize this behavior when we add ethylene glycol antifreeze to a car's radiator to lower the freezing point of the solution. The added solute also raises the boiling point of the solution above that of pure water, making it possible to operate the engine at a higher temperature.

Lowering of the freezing point and raising of the boiling point are physical properties of solutions that depend on the *quantity* (concentration) but not the *kind* or *identity* of the solute particles. Such properties are called **colligative properties**. (*Colligative* means “depending on the collection”; colligative properties depend on the collective effect of the number of solute particles.)

In addition to freezing-point lowering and boiling-point raising, vapor-pressure lowering and osmotic pressure are also colligative properties. As we examine each one, notice how solute concentration quantitatively affects the property.

Vapor-Pressure Lowering

A liquid in a closed container establishes equilibrium with its vapor. ∞ (Section 11.5) The *vapor pressure* is the pressure exerted by the vapor when it is at equilibrium with the liquid (that is, when the rate of vaporization equals the rate of condensation). A substance that has no measurable vapor pressure is *nonvolatile*, whereas one that exhibits a vapor pressure is *volatile*.

A solution consisting of a volatile liquid solvent and a nonvolatile solute forms spontaneously because of the increase in entropy that accompanies their mixing. In effect, the solvent molecules are stabilized in their liquid state by this process and thus have a lower tendency to escape into the vapor state. Therefore, when a nonvolatile solute is present, the vapor pressure of the solvent is lower than the vapor pressure of the pure solvent, as illustrated in ► FIGURE 13.21.

The vapor pressure of a volatile solvent above a solution containing a nonvolatile solute is proportional to the solvent's concentration in the solution. This relationship is expressed quantitatively by **Raoult's law**, which states that the partial pressure exerted

◀ **FIGURE 13.21 Vapor-pressure lowering.** The presence of nonvolatile solute particles in a liquid solvent results in a reduction of the vapor pressure above the liquid.

by solvent vapor above the solution, P_{solution} , equals the product of the mole fraction of the solvent, X_{solvent} , times the vapor pressure of the pure solvent, $P_{\text{solvent}}^{\circ}$:

$$P_{\text{solution}} = X_{\text{solvent}} P_{\text{solvent}}^{\circ} \quad [13.10]$$

For example, the vapor pressure of pure water at 20 °C is $P_{\text{H}_2\text{O}}^{\circ} = 17.5$ torr. Imagine holding the temperature constant while adding glucose ($\text{C}_6\text{H}_{12}\text{O}_6$) to the water so that the mole fractions in the resulting solution are $X_{\text{H}_2\text{O}} = 0.800$ and $X_{\text{C}_6\text{H}_{12}\text{O}_6} = 0.200$. According to Equation 13.10, the vapor pressure of the water above this solution is 80.0% of that of pure water:

$$P_{\text{solution}} = (0.800)(17.5 \text{ torr}) = 14.0 \text{ torr}$$

The presence of the nonvolatile solute lowers the vapor pressure of the volatile solvent by $17.5 \text{ torr} - 14.0 \text{ torr} = 3.5 \text{ torr}$.

The vapor-pressure lowering, ΔP , is directly proportional to the mole fraction of the solute, X_{solute} :

$$\Delta P = X_{\text{solute}} P_{\text{solvent}}^{\circ} \quad [13.11]$$

Thus, for the example of the solution of glucose in water, we have

$$\Delta P = X_{\text{C}_6\text{H}_{12}\text{O}_6} P_{\text{H}_2\text{O}}^{\circ} = (0.200)(17.5 \text{ torr}) = 3.50 \text{ torr}$$

The vapor-pressure lowering caused by adding a nonvolatile solute depends on the total concentration of solute particles, regardless of whether they are molecules or ions. Remember that vapor-pressure lowering is a colligative property, so its value for any solution depends on the concentration of solute particles and not on their kind or on their identity.

▲ GIVE IT SOME THOUGHT

Adding 1 mol of NaCl to 1 kg of water lowers the vapor pressure of water more than adding 1 mol of $\text{C}_6\text{H}_{12}\text{O}_6$. Explain.

SAMPLE EXERCISE 13.7 Calculation of Vapor Pressure of a Solution

Glycerin ($\text{C}_3\text{H}_8\text{O}_3$) is a nonvolatile nonelectrolyte with a density of 1.26 g/mL at 25 °C. Calculate the vapor pressure at 25 °C of a solution made by adding 50.0 mL of glycerin to 500.0 mL of water. The vapor pressure of pure water at 25 °C is 23.8 torr (Appendix B), and its density is 1.00 g/mL.

SOLUTION

Analyze Our goal is to calculate the vapor pressure of a solution, given the volumes of solute and solvent and the density of the solute.

Plan We can use Raoult's law (Equation 13.10) to calculate the vapor pressure of a solution. The mole fraction of the solvent in the solution, X_{solvent} , is the ratio of the number of moles of solvent (H_2O) to total moles of solution (moles $\text{C}_3\text{H}_8\text{O}_3$ + moles H_2O).

Solve To calculate the mole fraction of water in the solution, we must determine the number of moles of $\text{C}_3\text{H}_8\text{O}_3$ and H_2O :

$$\text{Moles } \text{C}_3\text{H}_8\text{O}_3 = (50.0 \text{ mL } \text{C}_3\text{H}_8\text{O}_3) \left(\frac{1.26 \text{ g } \text{C}_3\text{H}_8\text{O}_3}{1 \text{ mL } \text{C}_3\text{H}_8\text{O}_3} \right) \left(\frac{1 \text{ mol } \text{C}_3\text{H}_8\text{O}_3}{92.1 \text{ g } \text{C}_3\text{H}_8\text{O}_3} \right) = 0.684 \text{ mol}$$

$$\text{Moles } \text{H}_2\text{O} = (500.0 \text{ mL } \text{H}_2\text{O}) \left(\frac{1.00 \text{ g } \text{H}_2\text{O}}{1 \text{ mL } \text{H}_2\text{O}} \right) \left(\frac{1 \text{ mol } \text{H}_2\text{O}}{18.0 \text{ g } \text{H}_2\text{O}} \right) = 27.8 \text{ mol}$$

$$X_{\text{H}_2\text{O}} = \frac{\text{mol } \text{H}_2\text{O}}{\text{mol } \text{H}_2\text{O} + \text{mol } \text{C}_3\text{H}_8\text{O}_3} = \frac{27.8}{27.8 + 0.684} = 0.976$$

We now use Raoult's law to calculate the vapor pressure of water for the solution:

$$P_{\text{H}_2\text{O}} = X_{\text{H}_2\text{O}} P_{\text{H}_2\text{O}}^{\circ} = (0.976)(23.8 \text{ torr}) = 23.2 \text{ torr}$$

Comment The vapor pressure of the solution has been lowered by $23.8 \text{ torr} - 23.2 \text{ torr} = 0.6 \text{ torr}$ relative to that of pure water. The vapor-pressure lowering can be calculated directly using Equation 13.11 together with the mole fraction of the solute, $\text{C}_3\text{H}_8\text{O}_3$:

$\Delta P = X_{\text{C}_3\text{H}_8\text{O}_3} P_{\text{H}_2\text{O}}^{\circ} = (0.024)(23.8 \text{ torr}) = 0.57 \text{ torr}$. Notice that the use of Equation 13.11 gives one more significant figure than the number obtained by subtracting the vapor pressure of the solution from that of the pure solvent.

PRACTICE EXERCISE

The vapor pressure of pure water at 110°C is 1070 torr. A solution of ethylene glycol and water has a vapor pressure of 1.00 atm at 110°C . Assuming that Raoult's law is obeyed, what is the mole fraction of ethylene glycol in the solution?

Answer: 0.290

A CLOSER LOOK

IDEAL SOLUTIONS WITH TWO OR MORE VOLATILE COMPONENTS

Solutions sometimes have two or more volatile components. Gasoline, for example, is a solution of several volatile liquids. To gain some understanding of such mixtures, consider an ideal solution of two volatile liquids, A and B. (For our purposes here, it does not matter which we call the solute and which the solvent.) The partial pressures above the solution are given by Raoult's law:

$$P_A = X_A P_A^{\circ} \text{ and } P_B = X_B P_B^{\circ}$$

and the total vapor pressure above the solution is

$$P_{\text{total}} = P_A + P_B = X_A P_A^{\circ} + X_B P_B^{\circ}$$

Consider a mixture of 1.0 mol of benzene (C_6H_6) and 2.0 mol of toluene (C_7H_8) ($X_{\text{ben}} = 0.33$, $X_{\text{tol}} = 0.67$). At 20°C the vapor pressures of the pure substances are $P_{\text{ben}}^{\circ} = 75 \text{ torr}$ and $P_{\text{tol}}^{\circ} = 22 \text{ torr}$. Thus, the partial pressures above the solution are

$$P_{\text{ben}} = (0.33)(75 \text{ torr}) = 25 \text{ torr}$$

$$P_{\text{tol}} = (0.67)(22 \text{ torr}) = 15 \text{ torr}$$

and the total vapor pressure above the liquid is

$$P_{\text{total}} = P_{\text{ben}} + P_{\text{tol}} = 25 \text{ torr} + 15 \text{ torr} = 40 \text{ torr}$$

Note that the vapor is richer in benzene, the more volatile component.

The mole fraction of benzene in the vapor is given by the ratio of its vapor pressure to the total pressure (Equations 10.14 and 10.15):

$$X_{\text{ben}} \text{ in vapor} = \frac{P_{\text{ben}}}{P_{\text{total}}} = \frac{25 \text{ torr}}{40 \text{ torr}} = 0.63$$

Although benzene constitutes only 33% of the molecules in the solution, it makes up 63% of the molecules in the vapor.

When an ideal liquid solution containing two volatile components is in equilibrium with its vapor, the more volatile component will be relatively richer in the vapor. This fact forms the basis of *distillation*, a technique used to separate (or partially separate) mixtures containing volatile components. Distillation is the procedure by which a moonshiner obtains whiskey using a still and by which petrochemical plants achieve the separation of crude petroleum into gasoline, diesel fuel, lubricating oil, and so forth (◀ **FIGURE 13.22**). Distillation is also used routinely on a small scale in the laboratory.

RELATED EXERCISES: 13.67, 13.68

◀ **FIGURE 13.22** The volatile components of organic mixtures can be separated on an industrial scale.

An ideal gas is defined as one that obeys the ideal-gas equation ∞ (Section 10.4), and an **ideal solution** is defined as one that obeys Raoult's law. Whereas ideality for a gas arises from a complete lack of intermolecular interaction, ideality for a solution implies total uniformity of interaction. The molecules in an ideal solution all influence one another in the same way—in other words, solute–solute, solvent–solvent, and solute–solvent interactions are indistinguishable from one another. Real solutions best approximate ideal behavior when the solute concentration is low and solute and solvent have similar molecular sizes and take part in similar types of intermolecular attractions.

Many solutions do not obey Raoult's law exactly and so are not ideal. If, for instance, the solvent–solute interactions in a solution are weaker than either the solvent–solvent or solute–solute interactions, the vapor pressure tends to be greater than predicted by Raoult's law (that is, the vapor-pressure lowering is less than what Raoult's law predicts). When the solute–solvent interactions in a solution are exceptionally strong, as might be the case when hydrogen bonding exists, the vapor pressure is lower than Raoult's law predicts (the vapor-pressure lowering is *greater* than what the law predicts). Although you should be aware that these departures from ideality occur, we will ignore them for the remainder of this chapter.

Boiling-Point Elevation

In Sections 11.5 and 11.6 we examined the vapor pressures of pure substances and how to use them to construct phase diagrams. How does the phase diagram of a solution and, hence, its boiling and freezing points differ from that of the pure solvent? The addition of a nonvolatile solute lowers the vapor pressure of the solution. Thus, in **FIGURE 13.23** the vapor-pressure curve of the solution is shifted downward relative to the vapor-pressure curve of the pure solvent.

Recall from Section 11.5 that the normal boiling point of a liquid is the temperature at which its vapor pressure equals 1 atm. Because the solution has a lower vapor pressure than the pure solvent, a higher temperature is required for the solution to achieve a vapor pressure of 1 atm. As a result, *the boiling point of the solution is higher than that of the pure solvent*. This effect is seen in Figure 13.23. We find the normal boiling points of the pure solvent from the graph by locating the point where the horizontal line at 1 atm intersects the black vapor-pressure curve and then tracing this point down to the temperature axis. For the solution, the horizontal line at 1 atm intersects the blue vapor-pressure curve at a higher temperature, indicating that the solution has a higher boiling point than the pure solvent.

The increase in boiling point relative to that of the pure solvent, ΔT_b , is a positive quantity obtained by subtracting the boiling point of the pure solvent from the boiling point of the solution. The value of ΔT_b is directly proportional to the solution molality:

$$\Delta T_b = K_b m \quad [13.12]$$

The magnitude of K_b , which is called the **molal boiling-point-elevation constant**, depends only on the solvent. Some typical values for several common solvents are given in

FIGURE 13.23 Phase diagram illustrating boiling-point elevation.

TABLE 13.3 • Molal Boiling-Point-Elevation and Freezing-Point-Depression Constants

Solvent	Normal Boiling Point (°C)	K_b (°C/ m)	Normal Freezing Point (°C)	K_f (°C/ m)
Water, H ₂ O	100.0	0.51	0.0	1.86
Benzene, C ₆ H ₆	80.1	2.53	5.5	5.12
Ethanol, C ₂ H ₅ OH	78.4	1.22	-114.6	1.99
Carbon tetrachloride, CCl ₄	76.8	5.02	-22.3	29.8
Chloroform, CHCl ₃	61.2	3.63	-63.5	4.68

▲ **TABLE 13.3.** For water, the table shows $K_b = 0.51$ °C/ m , which means that the boiling point of any aqueous solution that is 1 m in nonvolatile solute particles is 0.51 °C higher than the boiling point of pure water. Because solutions generally do not behave ideally, the constants listed in Table 13.3 serve well only for solutions that are not too concentrated.

It is important to remember that boiling-point elevation is proportional to the *total* concentration of solute particles, regardless of whether the particles are molecules or ions. When NaCl dissolves in water, 2 mol of solute particles (1 mol of Na⁺ and 1 mol of Cl⁻) are formed for each mole of NaCl that dissolves. Therefore, a 1 m aqueous solution of NaCl is 1 m in Na⁺ and 1 m in Cl⁻, making it 2 m in total solute particles. As a result, the boiling-point elevation of a 1 m aqueous solution of NaCl is approximately $(2\ m)(0.51\ \text{°C}/m) = 1\ \text{°C}$, twice as large as the boiling-point elevation of a 1 m solution of a nonelectrolyte such as sucrose. Thus, to properly predict the effect of a particular solute on boiling-point elevation (or any other colligative property), it is important to know whether the solute is an electrolyte or a nonelectrolyte. ∞ (Sections 4.1 and 4.3)

▲ GIVE IT SOME THOUGHT

A solute dissolved in water causes the boiling point to increase by 0.51 °C. Does this necessarily mean that the concentration of the solute is 1.0 m ?

Freezing-Point Depression

The vapor-pressure curves for the liquid and solid phases meet at the triple point. ∞ (Section 11.6) In ▼ **FIGURE 13.24** we see that the triple-point temperature of the solution is lower than the triple-point temperature of pure liquid because the solution has a lower vapor pressure than the pure liquid.

▲ **FIGURE 13.24** Phase diagram illustrating freezing-point depression.

The freezing point of a solution is the temperature at which the first crystals of pure solvent form in equilibrium with the solution. Recall from Section 11.6 that the line representing the solid–liquid equilibrium rises nearly vertically from the triple point. Because the triple-point temperature of the solution is lower than that of the pure liquid, *the freezing point of the solution is lower than that of the pure liquid*. The decrease in freezing point, ΔT_f , is a positive quantity obtained by subtracting the freezing point of the solution from the freezing point of the pure solvent.

Like the boiling-point elevation, ΔT_f is directly proportional to solute molality:

$$\Delta T_f = K_f m \quad [13.13]$$

The values of K_f , the **molal freezing-point-depression constant**, for several common solvents are given in Table 13.3. For water, K_f is $1.86\text{ }^\circ\text{C}/m$. Therefore, any aqueous solution that is $1\text{ }m$ in nonvolatile solute particles (such as $1\text{ }m\text{ C}_6\text{H}_{12}\text{O}_6$ or $0.5\text{ }m\text{ NaCl}$) freezes at the temperature that is $1.86\text{ }^\circ\text{C}$ lower than the freezing point of pure water.

The freezing-point depression caused by solutes explains the use of antifreeze in cars and the use of calcium chloride (CaCl_2) to melt ice on roads during winter.

SAMPLE EXERCISE 13.8 Calculation of Boiling-Point Elevation and Freezing-Point Depression

Automotive antifreeze consists of ethylene glycol, $\text{CH}_2(\text{OH})\text{CH}_2(\text{OH})$, a nonvolatile nonelectrolyte. Calculate the boiling point and freezing point of a 25.0 mass % solution of ethylene glycol in water.

SOLUTION

Analyze We are given that a solution contains 25.0 mass % of a nonvolatile, nonelectrolyte solute and asked to calculate the boiling and freezing points of the solution. To do this, we need to calculate the boiling-point elevation and freezing-point depression.

Plan To calculate the boiling-point elevation and the freezing-point depression using Equations 13.12 and 13.13, we must express the concentration of the solution as molality. Let's assume for convenience that we have 1000 g of solution. Because the solution is 25.0 mass % ethylene glycol, the masses of ethylene glycol and water in the solution are 250 and 750 g, respectively. Using these quantities, we can calculate the molality of the solution, which we use with the molal boiling-point-elevation and freezing-point-depression constants (Table 13.3) to calculate ΔT_b and ΔT_f . We add ΔT_b to the boiling point and subtract ΔT_f from the freezing point of the solvent to obtain the boiling point and freezing point of the solution.

Solve The molality of the solution is calculated as follows:

$$\begin{aligned} \text{Molality} &= \frac{\text{moles C}_2\text{H}_6\text{O}_2}{\text{kilograms H}_2\text{O}} = \left(\frac{250\text{ g C}_2\text{H}_6\text{O}_2}{750\text{ g H}_2\text{O}} \right) \left(\frac{1\text{ mol C}_2\text{H}_6\text{O}_2}{62.1\text{ g C}_2\text{H}_6\text{O}_2} \right) \left(\frac{1000\text{ g H}_2\text{O}}{1\text{ kg H}_2\text{O}} \right) \\ &= 5.37\text{ }m \end{aligned}$$

We can now use Equations 13.12 and 13.13 to calculate the changes in the boiling and freezing points:

$$\begin{aligned} \Delta T_b &= K_b m = (0.51\text{ }^\circ\text{C}/m)(5.37\text{ }m) = 2.7\text{ }^\circ\text{C} \\ \Delta T_f &= K_f m = (1.86\text{ }^\circ\text{C}/m)(5.37\text{ }m) = 10.0\text{ }^\circ\text{C} \end{aligned}$$

Hence, the boiling and freezing points of the solution are

$$\begin{aligned} \text{Boiling point} &= (\text{normal bp of solvent}) + \Delta T_b \\ &= 100.0\text{ }^\circ\text{C} + 2.7\text{ }^\circ\text{C} = 102.7\text{ }^\circ\text{C} \\ \text{Freezing point} &= (\text{normal fp of solvent}) - \Delta T_f \\ &= 0.0\text{ }^\circ\text{C} - 10.0\text{ }^\circ\text{C} = -10.0\text{ }^\circ\text{C} \end{aligned}$$

Comment Notice that the solution is a liquid over a larger temperature range than the pure solvent.

PRACTICE EXERCISE

Calculate the freezing point of a solution containing 0.600 kg of CHCl_3 and 42.0 g of eucalyptol ($\text{C}_{10}\text{H}_{18}\text{O}$), a fragrant substance found in the leaves of eucalyptus trees. (See Table 13.3.)

Answer: $-65.6\text{ }^\circ\text{C}$

SAMPLE EXERCISE 13.9 Freezing-Point Depression in Aqueous Solutions

List the following aqueous solutions in order of their expected freezing point: 0.050 *m* CaCl₂, 0.15 *m* NaCl, 0.10 *m* HCl, 0.050 *m* CH₃COOH, 0.10 *m* C₁₂H₂₂O₁₁.

SOLUTION

Analyze We must order five aqueous solutions according to expected freezing points, based on molalities and the solute formulas.

Plan The lowest freezing point will correspond to the solution with the greatest concentration of solute particles. To determine the total concentration of solute particles in each case, we must determine whether the substance is a nonelectrolyte or an electrolyte and consider the number of ions formed when an electrolyte ionizes.

Solve CaCl₂, NaCl, and HCl are strong electrolytes, CH₃COOH (acetic acid) is a weak electrolyte, and C₁₂H₂₂O₁₁ is a nonelectrolyte. The molality of each solution in total particles is as follows:

Because the freezing points depend on the total molality of particles in solution, the expected ordering is 0.15 *m* NaCl (lowest freezing point), 0.10 *m* HCl, 0.050 *m* CaCl₂, 0.10 *m* C₁₂H₂₂O₁₁, and 0.050 *m* CH₃COOH (highest freezing point).

PRACTICE EXERCISE

Which of the following solutes will produce the largest increase in boiling point upon addition to 1 kg of water: 1 mol of Co(NO₃)₂, 2 mol of KCl, 3 mol of ethylene glycol (C₂H₆O₂)?

Answer: 2 mol of KCl because it contains the highest concentration of particles, 2 *m* K⁺ and 2 *m* Cl⁻, giving 4 *m* in all

Osmosis

Certain materials, including many membranes in biological systems and synthetic substances such as cellophane, are *semipermeable*. When in contact with a solution, these materials allow only small molecules—water molecules, for instance—to pass through their network of tiny pores.

Consider a situation in which only solvent molecules are able to pass through a semipermeable membrane placed between two solutions of different concentrations. The rate at which the solvent passes from the less concentrated solution (lower solute concentration but higher solvent concentration) to the more concentrated solution (higher solute concentration but lower solvent concentration) is greater than the rate in the opposite direction. Thus, there is a net movement of solvent molecules from the solution with a lower solute concentration into the one with a higher solute concentration. In this process, called **osmosis**, *the net movement of solvent is always toward the solution with the higher solute concentration*, as if the solutions were driven to attain equal concentrations.

► **FIGURE 13.25** shows the osmosis that occurs between an aqueous solution and pure water. The U-tube contains water on the left and an aqueous solution on the right. There is a net movement of water through the membrane from left to right. As a result, the liquid levels in the two arms become unequal. Eventually, the pressure difference resulting from the unequal liquid heights becomes so large that the net flow of water ceases. The pressure required to stop osmosis from a pure solvent to a solution is the **osmotic pressure** of the solution. If an external pressure equal to the osmotic pressure is applied to the solution, the liquid levels in the two arms can be equalized, as shown in the right panel of Figure 13.25.

GO FIGURE

If the pure water in the left arm of the U-tube is replaced by a solution more concentrated than the one in the right arm, what will happen?

▲ FIGURE 13.25 Osmosis.

The osmotic pressure obeys a law similar in form to the ideal-gas law, $\Pi V = nRT$, where Π is the osmotic pressure, V is the volume of the solution, n is the number of moles of solute, R is the ideal-gas constant, and T is the Kelvin temperature. From this equation, we can write

$$\Pi = \left(\frac{n}{V}\right)RT = MRT \quad [13.14]$$

where M is the molarity of the solution. Because the osmotic pressure for any solution depends on the solution concentration, osmotic pressure is a colligative property.

If two solutions of identical osmotic pressure are separated by a semipermeable membrane, no osmosis will occur. The two solutions are *isotonic* with respect to each other. If one solution is of lower osmotic pressure, it is *hypotonic* with respect to the more concentrated solution. The more concentrated solution is *hypertonic* with respect to the dilute solution.

GIVE IT SOME THOUGHT

Of two KBr solutions, one 0.50 *m* and the other 0.20 *m*, which is hypotonic with respect to the other?

Osmosis plays an important role in living systems. The membranes of red blood cells, for example, are semipermeable. Placing a red blood cell in a solution that is *hypertonic* relative to the intracellular solution (the solution inside the cells) causes water to move out of the cell (► FIGURE 13.26). This causes the cell to shrivel, a process called *crenation*. Placing the cell in a solution that is *hypotonic* relative to the intracellular fluid causes water to move into the cell. This may cause the cell to rupture, a process called *hemolysis*. People who need body fluids or nutrients replaced but cannot be fed orally are given solutions by intravenous (IV) infusion, which feeds nutrients directly into the veins. To prevent crenation or hemolysis of red blood cells, the IV solutions must be isotonic with the intracellular fluids of the blood cells.

GO FIGURE

If the fluid surrounding a patient's red blood cells is depleted in electrolytes, is crenation or hemolysis more likely to occur?

► **FIGURE 13.26** Osmosis through red blood cell wall.

SAMPLE EXERCISE 13.10 Calculation Involving Osmotic Pressure

The average osmotic pressure of blood is 7.7 atm at 25 °C. What molarity of glucose ($C_6H_{12}O_6$) will be isotonic with blood?

SOLUTION

Analyze We are asked to calculate the concentration of glucose in water that would be isotonic with blood, given that the osmotic pressure of blood at 25 °C is 7.7 atm.

Plan Because we are given the osmotic pressure and temperature, we can solve for the concentration, using Equation 13.14.

Solve

$$\Pi = MRT$$

$$M = \frac{\Pi}{RT} = \frac{7.7 \text{ atm}}{\left(0.0821 \frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)(298 \text{ K})} = 0.31 \text{ M}$$

Comment In clinical situations the concentrations of solutions are generally expressed as mass percentages. The mass percentage of a 0.31 M solution of glucose is 5.3%. The concentration of NaCl that is isotonic with blood is 0.16 M, because NaCl ionizes to form two particles, Na^+ and Cl^- (a 0.155 M solution of NaCl is 0.310 M in particles). A 0.16 M solution of NaCl is 0.9 mass % in NaCl. This kind of solution is known as a physiological saline solution.

PRACTICE EXERCISE

What is the osmotic pressure at 20 °C of a 0.0020 M sucrose ($C_{12}H_{22}O_{11}$) solution?

Answer: 0.048 atm, or 37 torr

There are many interesting biological examples of osmosis. A cucumber placed in concentrated brine loses water via osmosis and shrivels into a pickle. People who eat a lot of salty food retain water in tissue cells and intercellular space because of osmosis. The resultant swelling or puffiness is called *edema*. Water moves from soil into plant roots partly because of osmosis. Bacteria on salted meat or candied fruit lose water through osmosis, shrivel, and die—thus preserving the food.

Movement of a substance from an area where its concentration is high to an area where it is low is spontaneous. Biological cells transport water and other select materials through their membranes, permitting nutrients to enter and waste materials to exit. In some cases substances must be moved across the cell membrane from an area of low concentration to one of high concentration. This movement—called *active transport*—is not spontaneous, so cells must expend energy to do it.

GIVE IT SOME THOUGHT

Is the osmotic pressure of a 0.10 M solution of NaCl greater than, less than, or equal to that of a 0.10 M solution of KBr?

Determination of Molar Mass

The colligative properties of solutions provide a useful means of determining molar mass. Any of the four colligative properties can be used, as shown in Sample Exercises 13.11 and 13.12.

SAMPLE EXERCISE 13.11 Molar Mass from Freezing-Point Depression

A solution of an unknown nonvolatile nonelectrolyte was prepared by dissolving 0.250 g of the substance in 40.0 g of CCl_4 . The boiling point of the resultant solution was 0.357°C higher than that of the pure solvent. Calculate the molar mass of the solute.

SOLUTION

Analyze Our goal is to calculate the molar mass of a solute based on knowledge of the boiling-point elevation of its solution in CCl_4 , $\Delta T_b = 0.357^\circ\text{C}$, and the masses of solute and solvent. Table 13.3 gives K_b for the solvent (CCl_4), $K_b = 5.02^\circ\text{C}/m$.

Plan We can use Equation 13.12, $\Delta T_b = K_b m$, to calculate the molality of the solution. Then we can use molality and the quantity of solvent (40.0 g CCl_4) to calculate the number of moles of solute. Finally, the molar mass of the solute equals the number of grams per mole, so we divide the number of grams of solute (0.250 g) by the number of moles we have just calculated.

Solve From Equation 13.12 we have

$$\text{Molality} = \frac{\Delta T_b}{K_b} = \frac{0.357^\circ\text{C}}{5.02^\circ\text{C}/m} = 0.0711 m$$

Thus, the solution contains 0.0711 mol of solute per kilogram of solvent. The solution was prepared using 40.0 g = 0.0400 kg of solvent (CCl_4). The number of moles of solute in the solution is therefore

$$(0.0400 \text{ kg } \text{CCl}_4) \left(0.0711 \frac{\text{mol solute}}{\text{kg } \text{CCl}_4} \right) = 2.84 \times 10^{-3} \text{ mol solute}$$

The molar mass of the solute is the number of grams per mole of the substance:

$$\text{Molar mass} = \frac{0.250 \text{ g}}{2.84 \times 10^{-3} \text{ mol}} = 88.0 \text{ g/mol}$$

PRACTICE EXERCISE

Camphor ($\text{C}_{10}\text{H}_{16}\text{O}$) melts at 179.8°C , and it has a particularly large freezing-point-depression constant, $K_f = 40.0^\circ\text{C}/m$. When 0.186 g of an organic substance of unknown molar mass is dissolved in 22.01 g of liquid camphor, the freezing point of the mixture is found to be 176.7°C . What is the molar mass of the solute?

Answer: 110 g/mol

SAMPLE EXERCISE 13.12 Molar Mass from Osmotic Pressure

The osmotic pressure of an aqueous solution of a certain protein was measured to determine the protein's molar mass. The solution contained 3.50 mg of protein dissolved in sufficient water to form 5.00 mL of solution. The osmotic pressure of the solution at 25°C was found to be 1.54 torr. Treating the protein as a nonelectrolyte, calculate its molar mass.

SOLUTION

Analyze Our goal is to calculate the molar mass of a high-molecular-mass protein, based on its osmotic pressure and a knowledge of the mass of protein and solution volume.

Plan The temperature ($T = 25^\circ\text{C}$) and osmotic pressure ($\Pi = 1.54 \text{ torr}$) are given, and we know the value of R so we can use Equation 13.14 to calculate the molarity of the solution, M . In doing so, we must convert temperature from $^\circ\text{C}$ to K and the osmotic pressure from torr to atm. We then use the molarity and the volume of the solution (5.00 mL) to determine the number of moles of solute. Finally, we obtain the molar mass by dividing the mass of the solute (3.50 mg) by the number of moles of solute.

Solve Solving Equation 13.14 for molarity gives

$$\text{Molarity} = \frac{\Pi}{RT} = \frac{(1.54 \text{ torr})\left(\frac{1 \text{ atm}}{760 \text{ torr}}\right)}{\left(0.0821 \frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)(298 \text{ K})} = 8.28 \times 10^{-5} \frac{\text{mol}}{\text{L}}$$

Because the volume of the solution is 5.00 mL = 5.00×10^{-3} L, the number of moles of protein must be

$$\text{Moles} = (8.28 \times 10^{-5} \text{ mol/L})(5.00 \times 10^{-3} \text{ L}) = 4.14 \times 10^{-7} \text{ mol}$$

The molar mass is the number of grams per mole of the substance. The sample has a mass of 3.50 mg = 3.50×10^{-3} g. The molar mass is the number of grams divided by the number of moles:

$$\text{Molar mass} = \frac{\text{grams}}{\text{moles}} = \frac{3.50 \times 10^{-3} \text{ g}}{4.14 \times 10^{-7} \text{ mol}} = 8.45 \times 10^3 \text{ g/mol}$$

Comment Because small pressures can be measured easily and accurately, osmotic pressure measurements provide a useful way to determine the molar masses of large molecules.

PRACTICE EXERCISE

A sample of 2.05 g of polystyrene of uniform polymer chain length was dissolved in enough toluene to form 0.100 L of solution. The osmotic pressure of this solution was found to be 1.21 kPa at 25 °C. Calculate the molar mass of the polystyrene.

Answer: 4.20×10^4 g/mol

A CLOSER LOOK

COLLIGATIVE PROPERTIES OF ELECTROLYTE SOLUTIONS

The colligative properties of solutions depend on the *total* concentration of solute particles, regardless of whether the particles are ions or molecules. Thus, we expect a 0.100 *m* solution of NaCl to have a freezing-point depression of $(0.200 \text{ } m)(1.86 \text{ } ^\circ\text{C}/m) = 0.372 \text{ } ^\circ\text{C}$ because it is 0.100 *m* in $\text{Na}^+(aq)$ and 0.100 *m* in $\text{Cl}^-(aq)$. The measured freezing-point depression is only 0.348 °C, however, and the situation is similar for other strong electrolytes. A 0.100 *m* solution of KCl, for example, freezes at $-0.344 \text{ } ^\circ\text{C}$.

The difference between expected and observed colligative properties for strong electrolytes is due to electrostatic attractions between ions. As the ions move about in solution, ions of opposite charge collide and “stick together” for brief moments. While they are together, they behave as a single particle called an *ion pair* (► FIGURE 13.27). The number of independent particles is thereby reduced, causing a reduction in the freezing-point depression (as well as in boiling-point elevation, vapor-pressure reduction, and osmotic pressure).

One measure of the extent to which electrolytes dissociate is the *van't Hoff factor*, *i*. This factor is the ratio of the actual value of a colligative property to the value calculated when the substance is assumed to be a nonelectrolyte. Using the freezing-point depression, for example, we have

$$i = \frac{\Delta T_f(\text{measured})}{\Delta T_f(\text{calculated for nonelectrolyte})} \quad [13.15]$$

The limiting value of *i* can be determined for a salt from the number of ions per formula unit. For NaCl, for example, the limiting van't Hoff

factor is 2 because NaCl consists of one Na^+ and one Cl^- per formula unit; for K_2SO_4 it is 3 because K_2SO_4 consists of two K^+ and one SO_4^{2-} per formula unit. In the absence of any information about the actual value of *i* for a solution, we will use the limiting value in calculations.

▲ FIGURE 13.27 Ion pairing and colligative properties. A solution of NaCl contains not only separated $\text{Na}^+(aq)$ and $\text{Cl}^-(aq)$ ions but ion pairs as well.

Two trends are evident in ► **TABLE 13.4**, which gives measured van't Hoff factors for several substances at different dilutions. First, dilution affects the value of i for electrolytes; the more dilute the solution, the more closely i approaches the limiting value. Thus, we conclude that the extent of ion pairing in electrolyte solutions decreases upon dilution. Second, the lower the charges on the ions, the less i departs from the limiting value because the extent of ion pairing decreases as the ionic charges decrease. Both trends are consistent with simple electrostatics: The force of interaction between charged particles decreases as their separation increases and as their charges decrease.

TABLE 13.4 • van't Hoff Factors for Several Substances at 25 °C

Compound	Concentration			Limiting Value
	0.100 <i>m</i>	0.0100 <i>m</i>	0.00100 <i>m</i>	
Sucrose	1.00	1.00	1.00	1.00
NaCl	1.87	1.94	1.97	2.00
K ₂ SO ₄	2.32	2.70	2.84	3.00
MgSO ₄	1.21	1.53	1.82	2.00

13.6 COLLOIDS

Finely divided clay particles dispersed in water eventually settle out because of gravity. This happens because clay molecules, which consist of thousands or even millions of atoms, are much larger than most molecules. In contrast, the dispersed particles in a solution (ions in a salt solution, say, or glucose molecules in a sugar solution) are smaller. Between these extremes lie dispersed particles that are larger than typical molecules but not so large that the components of the mixture separate under the influence of gravity. These intermediate types of dispersions are called either **colloidal dispersions** or simply **colloids**. Colloids form the dividing line between solutions and heterogeneous mixtures. Like solutions, colloids can be gases, liquids, or solids. Examples of each are listed in ▼ **TABLE 13.5**.

Particle size can be used to classify a mixture as colloid or solution. Colloid particles range in diameter from 5 to 1000 nm; solute particles are smaller than 5 nm in diameter. A colloid particle may even consist of a single giant molecule. The hemoglobin molecule, for example, which carries oxygen in your blood, has molecular dimensions of $6.5 \times 5.5 \times 5.0$ nm and a molar mass of 64,500 g/mol.

Although colloid particles may be so small that the dispersion appears uniform even under a microscope, they are large enough to scatter light. Consequently, most colloids appear cloudy or opaque unless they are very dilute. (Homogenized milk is a colloid.) Furthermore, because they scatter light, a light beam can be seen as it passes through a colloidal dispersion (► **FIGURE 13.28**). This scattering of light by colloidal particles, known as the **Tyndall effect**, makes it possible to see the light beam of an automobile on a dusty dirt road or the sunlight coming through a forest canopy

TABLE 13.5 • Types of Colloids

Phase of Colloid	Dispersing (solvent-like) Substance	Dispersed (solute-like) Substance	Colloid Type	Example
Gas	Gas	Gas	—	None (all are solutions)
Gas	Gas	Liquid	Aerosol	Fog
Gas	Gas	Solid	Aerosol	Smoke
Liquid	Liquid	Gas	Foam	Whipped cream
Liquid	Liquid	Liquid	Emulsion	Milk
Liquid	Liquid	Solid	Sol	Paint
Solid	Solid	Gas	Solid foam	Marshmallow
Solid	Solid	Liquid	Solid emulsion	Butter
Solid	Solid	Solid	Solid sol	Ruby glass

► **FIGURE 13.28** Tyndall effect in the laboratory. The glass on the right contains a colloidal dispersion; that on the left contains a solution.

(▼ **FIGURE 13.29**). Not all wavelengths are scattered to the same extent. Colors at the violet end of the visible spectrum are scattered more than those at the red end. As a result, brilliant red sunsets are seen when the sun is near the horizon and the air contains dust, smoke, or other particles of colloidal size.

Hydrophilic and Hydrophobic Colloids

The most important colloids are those in which the dispersing medium is water. These colloids may be **hydrophilic** (water loving) or **hydrophobic** (water fearing). Hydrophilic colloids are most like the solutions that we have previously examined. In the human body the extremely large molecules that make up such important substances as enzymes and antibodies are kept in suspension by interaction with surrounding water molecules. A hydrophilic molecule folds in such a way that its hydrophobic groups are away from the water molecules, on the “inside” of the folded molecule, while its hydrophilic, polar groups are on the surface, interacting with the water molecules. The hydrophilic groups generally contain oxygen or nitrogen and often carry a charge (► **FIGURE 13.30**).

Hydrophobic colloids can be dispersed in water only if they are stabilized in some way. Otherwise, their natural lack of affinity for water causes them to separate from the water. One method of stabilization involves adsorbing ions on the surface of the hydrophobic particles (► **FIGURE 13.31**). (*Adsorption* means to adhere to a surface. It differs from *absorption*, which means to pass into the interior, as when a sponge absorbs water.) The adsorbed ions can interact with water, thereby stabilizing the colloid. At the same time, the repulsion between adsorbed ions on neighboring colloid particles keeps the particles from sticking together rather than dispersing in the water.

► **FIGURE 13.29** Tyndall effect in nature.

GO FIGURE

What is the chemical composition of the groups that carry a negative charge?

▲ **FIGURE 13.30** Hydrophilic colloidal particle. Examples of the hydrophilic groups that help to keep a giant molecule (macromolecule) suspended in water.

▲ **FIGURE 13.31** Hydrophobic colloids stabilized by adsorbed anions.

Hydrophobic colloids can also be stabilized by hydrophilic groups on their surfaces. Oil drops are hydrophobic, for example, so they do not remain suspended in water. Instead, they aggregate, forming an oil slick on the water surface. Sodium stearate (► **FIGURE 13.32**), or any similar substance having one end that is hydrophilic (either polar or charged) and one end that is hydrophobic (nonpolar), will stabilize a suspension of oil in water. Stabilization results from the interaction of the hydrophobic ends of the stearate ions with the oil drops and the hydrophilic ends with the water.

GIVE IT SOME THOUGHT

Why don't oil drops stabilized by sodium stearate coagulate to form larger oil drops?

GO FIGURE

Which kind of intermolecular force attracts the stearate ion to the oil drop?

▲ FIGURE 13.32 Stabilization of an emulsion of oil in water by stearate ions.

Colloid stabilization has an interesting application in the human digestive system. When fats in our diet reach the small intestine, a hormone causes the gallbladder to excrete a fluid called bile. Among the components of bile are compounds that have chemical structures similar to sodium stearate; that is, they have a hydrophilic (polar) end and a hydrophobic (nonpolar) end. These compounds emulsify the fats in the intestine and thus permit digestion and absorption of fat-soluble vitamins through the intestinal wall. The term *emulsify* means “to form an emulsion,” a suspension of one liquid in another, with milk being one example (Table 13.5). A substance that aids in the formation of an emulsion is called an emulsifying agent. If you read the labels on foods and other materials, you will find that a variety of chemicals are used as emulsifying agents. These chemicals typically have a hydrophilic end and a hydrophobic end.

Removal of Colloidal Particles

Colloidal particles frequently must be removed from a dispersing medium, as in the removal of smoke from smokestacks or butterfat from milk. Because colloidal particles are too small to be separated by simple filtration, they must be enlarged in a process called *coagulation*. The coagulated particles can then be separated by filtration or merely allowed to settle out of the dispersing medium.

Heating a colloidal dispersion or adding an electrolyte may bring about coagulation. Heating increases the particle motion and so the number of collisions. The particles get larger as they stick together after colliding. Addition of an electrolyte neutralizes the surface charges of the particles, thereby removing the electrostatic repulsions that prevent them from coming together. Wherever a river empties into the ocean, for example, the clay suspended in the river is deposited as a delta as it mixes with the electrolytes in the salt water.

A semipermeable membrane can be used to separate ions from colloidal particles because the ions can pass through the membrane but the colloidal particles cannot. This type of separation is known as *dialysis* and is used to purify blood in artificial kidney machines. Our kidneys normally remove waste products from blood. In a kidney machine, blood is circulated through a dialyzing tube immersed in a washing solution. The solution contains the same concentrations and kinds of ions as blood but no waste products. Dissolved wastes therefore dialyze out of the blood, but the large colloidal particles such as proteins do not.

CHEMISTRY AND LIFE

SICKLE-CELL ANEMIA

Our blood contains the complex protein *hemoglobin*, which carries oxygen from the lungs to other parts of the body. In the genetic disease known as *sickle-cell anemia*, hemoglobin molecules are abnormal and have a lower solubility, especially in their unoxylated form. Consequently, as much as 85% of the hemoglobin in red blood cells crystallizes out of solution.

The cause of the insolubility is a structural change in one part of an amino acid. Normal hemoglobin molecules contain an amino acid that has a $-\text{CH}_2\text{CH}_2\text{COOH}$ chain:

The polarity of the $-\text{COOH}$ group contributes to the solubility of the hemoglobin molecule in water. In the hemoglobin molecules of sickle-cell anemia patients, the $-\text{CH}_2\text{CH}_2\text{COOH}$ chain is absent and in its place we find only the nonpolar (hydrophobic) $-\text{CH}(\text{CH}_3)_2$ group:

This change leads to the aggregation of the defective form of hemoglobin into particles too large to remain suspended in biological fluids. It also causes the cells to distort into the sickle shape shown in **▼ FIGURE 13.33**. The sickled cells tend to clog capillaries, causing severe pain, weakness, and the gradual deterioration of vital organs. The disease is hereditary, and if both parents carry the defective genes, it is likely that their children will possess only abnormal hemoglobin.

▲ FIGURE 13.33 Normal and sickled red blood cells. Normal red blood cells are about 1×10^{-3} mm in diameter.

SAMPLE INTEGRATIVE EXERCISE Putting Concepts Together

A 0.100-L solution is made by dissolving 0.441 g of $\text{CaCl}_2(\text{s})$ in water. (a) Calculate the osmotic pressure of this solution at 27°C , assuming that it is completely dissociated into its component ions. (b) The measured osmotic pressure of this solution is 2.56 atm at 27°C . Explain why it is less than the value calculated in (a), and calculate the van't Hoff factor, i , for the solute in this solution. (See the "A Closer Look" box on Colligative Properties of Electrolyte Solutions in Section 13.5.) (c) The enthalpy of solution for CaCl_2 is $\Delta H = -81.3$ kJ/mol. If the final temperature of the solution is 27°C , what was its initial temperature? (Assume that the density of the solution is 1.00 g/mL, that its specific heat is 4.18 J/g-K, and that the solution loses no heat to its surroundings.)

SOLUTION

(a) The osmotic pressure is given by Equation 13.14, $\Pi = MRT$. We know the temperature, $T = 27^\circ\text{C} = 300$ K, and the gas constant, $R = 0.0821$ L-atm/mol-K. We can calculate the molarity of the solution from the mass of CaCl_2 and the volume of the solution:

$$\text{Molarity} = \left(\frac{0.441 \text{ g CaCl}_2}{0.100 \text{ L}} \right) \left(\frac{1 \text{ mol CaCl}_2}{110 \text{ g CaCl}_2} \right) = 0.0397 \text{ mol CaCl}_2/\text{L}$$

Soluble ionic compounds are strong electrolytes. ∞ (Sections 4.1 and 4.3) Thus, CaCl_2 consists of metal cations (Ca^{2+}) and nonmetal anions (Cl^-). When completely dissociated, each CaCl_2 unit forms three ions (one Ca^{2+} and two Cl^-). Hence, the total concentration of ions in the solution is $(3)(0.0397 \text{ M}) = 0.119 \text{ M}$, and the calculated osmotic pressure is

$$\Pi = MRT = (0.119 \text{ mol/L})(0.0821 \text{ L-atm/mol-K})(300 \text{ K}) = 2.93 \text{ atm}$$

(b) The actual values of colligative properties of electrolytes are less than those calculated because the electrostatic interactions between ions limit their independent movements. In this case the van't Hoff factor, which measures the extent to which electrolytes actually dissociate into ions, is given by

$$i = \frac{\Pi(\text{measured})}{\Pi(\text{calculated for nonelectrolyte})} = \frac{2.56 \text{ atm}}{(0.0397 \text{ mol/L})(0.0821 \text{ L}\cdot\text{atm/mol}\cdot\text{K})(300 \text{ K})} = 2.62$$

Thus, the solution behaves as if the CaCl_2 has dissociated into 2.62 particles instead of the ideal 3.

(c) If the solution is 0.0397 M in CaCl_2 and has a total volume of 0.100 L, the number of moles of solute is $(0.100 \text{ L})(0.0397 \text{ mol/L}) = 0.00397 \text{ mol}$. Hence, the quantity of heat generated in forming the solution is $(0.00397 \text{ mol})(-81.3 \text{ kJ/mol}) = -0.323 \text{ kJ}$. The solution absorbs this heat, causing its temperature to increase. The relationship between temperature change and heat is given by Equation 5.22:

$$q = (\text{specific heat})(\text{grams})(\Delta T)$$

The heat absorbed by the solution is $q = +0.323 \text{ kJ} = 323 \text{ J}$. The mass of the 0.100 L of solution is $(100 \text{ mL})(1.00 \text{ g/mL}) = 100 \text{ g}$ (to three significant figures). Thus, the temperature change is

$$\Delta T = \frac{q}{(\text{specific heat of solution})(\text{grams of solution})} = \frac{323 \text{ J}}{(4.18 \text{ J/g}\cdot\text{K})(100 \text{ g})} = 0.773 \text{ K}$$

A kelvin has the same size as a degree Celsius. ∞ (Section 1.4) Because the solution temperature increases by 0.773 °C, the initial temperature was $27.0 \text{ °C} - 0.773 \text{ °C} = 26.2 \text{ °C}$.

CHAPTER SUMMARY AND KEY TERMS

SECTION 13.1 Solutions form when one substance disperses uniformly throughout another. The attractive interaction of solvent molecules with solute is called **solvation**. When the solvent is water, the interaction is called **hydration**. The dissolution of ionic substances in water is promoted by hydration of the separated ions by the polar water molecules. The overall enthalpy change upon solution formation may be either positive or negative. Solution formation is favored both by a positive entropy change, corresponding to an increased dispersal of the components of the solution, and by a negative enthalpy change, indicating an exothermic process.

SECTION 13.2 The equilibrium between a saturated solution and undissolved solute is dynamic; the process of solution and the reverse process, **crystallization**, occur simultaneously. In a solution in equilibrium with undissolved solute, the two processes occur at equal rates, giving a **saturated** solution. If there is less solute present than is needed to saturate the solution, the solution is **unsaturated**. When solute concentration is greater than the equilibrium concentration value, the solution is **supersaturated**. This is an unstable condition, and separation of some solute from the solution will occur if the process is initiated with a solute seed crystal. The amount of solute needed to form a saturated solution at any particular temperature is the **solubility** of that solute at that temperature.

SECTION 13.3 The solubility of one substance in another depends on the tendency of systems to become more random, by becoming more dispersed in space, and on the relative intermolecular solute–solute and solvent–solvent energies compared with solute–solvent interactions. Polar and ionic solutes tend to dissolve in polar solvents, and nonpolar solutes tend to dissolve in nonpolar solvents (“like dissolves like”). Liquids that mix in all proportions are **miscible**; those

that do not dissolve significantly in one another are **immiscible**. Hydrogen-bonding interactions between solute and solvent often play an important role in determining solubility; for example, ethanol and water, whose molecules form hydrogen bonds with each other, are miscible. The solubilities of gases in a liquid are generally proportional to the pressure of the gas over the solution, as expressed by **Henry's law**: $S_g = kP_g$. The solubilities of most solid solutes in water increase as the temperature of the solution increases. In contrast, the solubilities of gases in water generally decrease with increasing temperature.

SECTION 13.4 Concentrations of solutions can be expressed quantitatively by several different measures, including **mass percentage** [(mass solute/mass solution) $\times 10^2$], **parts per million (ppm)**, **parts per billion (ppb)**, and mole fraction. Molarity, M , is defined as moles of solute per liter of solution; **molality**, m , is defined as moles of solute per kg of solvent. Molarity can be converted to these other concentration units if the density of the solution is known.

SECTION 13.5 A physical property of a solution that depends on the concentration of solute particles present, regardless of the nature of the solute, is a **colligative property**. Colligative properties include vapor-pressure lowering, freezing-point lowering, boiling-point elevation, and osmotic pressure. **Raoult's law** expresses the lowering of vapor pressure. An **ideal solution** obeys Raoult's law. Differences in solvent–solute as compared with solvent–solvent and solute–solute intermolecular forces cause many solutions to depart from ideal behavior.

A solution containing a nonvolatile solute possesses a higher boiling point than the pure solvent. The **molal boiling-point-elevation constant**, K_b , represents the increase in boiling point for a 1 m solution of solute particles as compared with the pure solvent. Similarly, the

molal freezing-point-depression constant, K_f , measures the lowering of the freezing point of a solution for a 1 *m* solution of solute particles. The temperature changes are given by the equations $\Delta T_b = K_b m$ and $\Delta T_f = K_f m$. When NaCl dissolves in water, two moles of solute particles are formed for each mole of dissolved salt. The boiling point or freezing point is thus elevated or depressed, respectively, approximately twice as much as that of a nonelectrolyte solution of the same concentration. Similar considerations apply to other strong electrolytes.

Osmosis is the movement of solvent molecules through a semipermeable membrane from a less concentrated to a more concentrated solution. This net movement of solvent generates an **osmotic pressure**, Π , which can be measured in units of gas pressure, such as atm. The osmotic pressure of a solution is proportional to the solution molarity: $\Pi = MRT$. Osmosis is a very important process in living systems, in which cell walls act as semipermeable membranes, permitting the passage of water but restricting the passage of ionic and macromolecular components.

SECTION 13.6 Particles that are large on the molecular scale but still small enough to remain suspended indefinitely in a solvent system form **colloids**, or **colloidal dispersions**. Colloids, which are intermediate between solutions and heterogeneous mixtures, have many practical applications. One useful physical property of colloids, the scattering of visible light, is referred to as the **Tyndall effect**. Aqueous colloids are classified as **hydrophilic** or **hydrophobic**. Hydrophilic colloids are common in living organisms, in which large molecular aggregates (enzymes, antibodies) remain suspended because they have many polar, or charged, atomic groups on their surfaces that interact with water. Hydrophobic colloids, such as small droplets of oil, may remain in suspension through adsorption of charged particles on their surfaces.

KEY SKILLS

- Describe how enthalpy and entropy changes affect solution formation. (Section 13.1)
- Describe the relationship between intermolecular forces and solubility, including use of the “like dissolves like” rule. (Sections 13.1 and 13.3)
- Describe the role of equilibrium in the solution process and its relationship to the solubility of a solute. (Section 13.2)
- Describe the effect of temperature on the solubility of solids and gases. (Section 13.3)
- Describe the relationship between the partial pressure of a gas and its solubility. (Section 13.3)
- Calculate the concentration of a solution in terms of molarity, molality, mole fraction, percent composition, and parts per million and be able to interconvert between them. (Section 13.4)
- Describe what a colligative property is and explain the difference between the effects of nonelectrolytes and electrolytes on colligative properties. (Section 13.5)
- Calculate the vapor pressure of a solvent over a solution. (Section 13.5)
- Calculate the boiling-point elevation and freezing-point depression of a solution. (Section 13.5)
- Calculate the osmotic pressure of a solution. (Section 13.5)
- Explain the difference between a solution and a colloid. (Section 13.6)

KEY EQUATIONS

- $S_g = kP_g$ [13.4] Henry’s law, relating gas solubility to partial pressure
- Mass % of component = $\frac{\text{mass of component in soln}}{\text{total mass of soln}} \times 100$ [13.5] Defining concentration in terms of mass percent
- ppm of component = $\frac{\text{mass of component in soln}}{\text{total mass of soln}} \times 10^6$ [13.6] Defining concentration in terms of parts per million (ppm)
- Mole fraction of component = $\frac{\text{moles of component}}{\text{total moles of all components}}$ [13.7] Defining concentration in terms of mole fraction
- Molarity = $\frac{\text{moles of solute}}{\text{liters of soln}}$ [13.8] Defining concentration in terms of molarity
- Molality = $\frac{\text{moles of solute}}{\text{kilograms of solvent}}$ [13.9] Defining concentration in terms of molality
- $P_{\text{solution}} = X_{\text{solvent}} P_{\text{solvent}}^\circ$ [13.10] Raoult’s law, calculating vapor pressure of solvent above a solution
- $\Delta T_b = K_b m$ [13.12] Calculating the boiling-point elevation of a solution
- $\Delta T_f = K_f m$ [13.13] Calculating the freezing-point depression of a solution
- $\Pi = \left(\frac{n}{V}\right)RT = MRT$ [13.14] Calculating the osmotic pressure of a solution

EXERCISES

VISUALIZING CONCEPTS

13.1 Rank the contents of the following containers in order of increasing entropy: [Section 13.1]

13.2 This figure shows the interaction of a cation with surrounding water molecules.

Would you expect the energy of ion–solvent interaction to be greater for Na^+ or Li^+ ? Explain. [Section 13.1]

- 13.3 How does the lattice energy of an ionic solid affect its solubility in water? [Section 13.1]
- 13.4 A quantity of the blue solid on the left in Figure 13.7 is placed in an oven and heated for a time. It slowly turns from blue to the white of the solid on the right. What has occurred? [Section 13.1]
- 13.5 Which of the following is the best representation of a saturated solution? Explain your reasoning. [Section 13.2]

13.6 The solubility of Xe in water at 1 atm pressure and 20 °C is approximately $5 \times 10^{-3} M$. Compare this with the solubilities of Ar and Kr in water (Table 13.1) and explain what properties of the rare gas atoms account for the variation in solubility. [Section 13.3]

13.7 The structures of vitamins E and B_6 are shown below. Predict which is largely water soluble and which is largely fat soluble. Explain. [Section 13.3]

13.8 If you wanted to prepare a solution of CO in water at 25 °C in which the CO concentration was 2.5 mM, what pressure of CO would you need to use? (See Figure 13.19.) [Section 13.3]

13.9 The figure shows two identical volumetric flasks containing the same solution at two temperatures.

- (a) Does the molarity of the solution change with the change in temperature? Explain.
- (b) Does the molality of the solution change with the change in temperature? Explain. [Section 13.4]

- 13.10 The following diagram shows the vapor-pressure curves of a volatile solvent and a solution of that solvent containing a nonvolatile solute. (a) Which line represents the solution? (b) What are the normal boiling points of the solvent and the solution? [Section 13.5]

- 13.11 Suppose you had a balloon made of some highly flexible semipermeable membrane. The balloon is filled completely with a 0.2 M solution of some solute and is submerged in a 0.1 M solution of the same solute:

Initially, the volume of solution in the balloon is 0.25 L. Assuming the volume outside the semipermeable membrane is large, as the illustration shows, what would you expect for the solution volume inside the balloon once the system has come to equilibrium through osmosis? [Section 13.5]

- 13.12 The molecule *n*-octylglucoside, shown here, is widely used in biochemical research as a nonionic detergent for “solubilizing” large hydrophobic protein molecules. What characteristics of this molecule are important for its use in this way? [Section 13.6]

THE SOLUTION PROCESS (section 13.1)

- 13.13 In general, the attractive intermolecular forces between solvent and solute particles must be comparable or greater than solute–solute interactions for significant solubility to occur. Explain this statement in terms of the overall energetics of solution formation.
- 13.14 (a) Considering the energetics of solute–solute, solvent–solvent, and solute–solvent interactions, explain why NaCl dissolves in water but not in benzene (C_6H_6). (b) What factors cause a cation to be strongly hydrated?
- 13.15 Indicate the type of solute–solvent interaction (Section 11.2) that should be most important in each of the following solutions: (a) CCl_4 in benzene (C_6H_6), (b) methanol (CH_3OH) in water, (c) KBr in water, (d) HCl in acetonitrile (CH_3CN).
- 13.16 Indicate the principal type of solute–solvent interaction in each of the following solutions and rank the solutions from weakest to strongest solute–solvent interaction: (a) KCl in water, (b) CH_2Cl_2 in benzene (C_6H_6), (c) methanol (CH_3OH) in water.
- 13.17 An ionic compound has a very negative ΔH_{soln} in water. Would you expect it to be very soluble or nearly insoluble in water? Explain in terms of the enthalpy and entropy changes that accompany the process.
- 13.18 When ammonium chloride dissolves in water, the solution becomes colder. (a) Is the solution process exothermic or endothermic? (b) Why does the solution form?
- 13.19 (a) In Equation 13.1 which of the enthalpy terms for dissolving an ionic solid would correspond to the lattice energy? (b) Which energy term in this equation is always exothermic?
- 13.20 The schematic diagram of the solution process as the net sum of three steps in Figure 13.4 does not show the relative magnitudes of the three components because these will vary from case to case. For the dissolution of LiCl in water, $\Delta H_{soln} = -37$ kJ/mol. Which of the three enthalpy changes would you expect to be much more negative than the other two? Explain.
- 13.21 When two nonpolar organic liquids such as hexane (C_6H_{14}) and heptane (C_7H_{16}) are mixed, the enthalpy change that occurs is generally quite small. (a) Use the enthalpy diagram in Figure 13.4 to explain why. (b) Given that $\Delta H_{soln} \approx 0$, explain why hexane and heptane spontaneously form a solution.
- 13.22 The enthalpy of solution of KBr in water is about +198 kJ/mol. Nevertheless, the solubility of KBr in water is relatively high. Why does the solution process occur even though it is endothermic?

SATURATED SOLUTIONS; FACTORS AFFECTING SOLUBILITY (sections 13.2 and 13.3)

13.23 The solubility of $\text{Cr}(\text{NO}_3)_3 \cdot 9 \text{H}_2\text{O}$ in water is 208 g per 100 g of water at 15 °C. A solution of $\text{Cr}(\text{NO}_3)_3 \cdot 9 \text{H}_2\text{O}$ in water at 35 °C is formed by dissolving 324 g in 100 g water. When this solution is slowly cooled to 15 °C, no precipitate forms. (a) What term describes this solution? (b) What action might you take to initiate crystallization? Use molecular-level processes to explain how your suggested procedure works.

13.24 The solubility of $\text{MnSO}_4 \cdot \text{H}_2\text{O}$ in water at 20 °C is 70 g per 100 mL of water. (a) Is a 1.22 M solution of $\text{MnSO}_4 \cdot \text{H}_2\text{O}$ in water at 20 °C saturated, supersaturated, or unsaturated? (b) Given a solution of $\text{MnSO}_4 \cdot \text{H}_2\text{O}$ of unknown concentration, what experiment could you perform to determine whether the new solution is saturated, supersaturated, or unsaturated?

13.25 By referring to Figure 13.18, determine whether the addition of 40.0 g of each of the following ionic solids to 100 g of water at 40 °C will lead to a saturated solution: (a) NaNO_3 , (b) KCl , (c) $\text{K}_2\text{Cr}_2\text{O}_7$, (d) $\text{Pb}(\text{NO}_3)_2$.

13.26 By referring to Figure 13.18, determine the mass of each of the following salts required to form a saturated solution in 250 g of water at 30 °C: (a) KClO_3 , (b) $\text{Pb}(\text{NO}_3)_2$, (c) $\text{Ce}_2(\text{SO}_4)_3$.

13.27 Water and glycerol, $\text{CH}_2(\text{OH})\text{CH}(\text{OH})\text{CH}_2\text{OH}$, are miscible in all proportions. What does this mean? How do the OH groups of the alcohol molecule contribute to this miscibility?

13.28 Oil and water are immiscible. What does this mean? Explain in terms of the structural features of their respective molecules and the forces between them.

13.29 Common laboratory solvents include acetone (CH_3COCH_3), methanol (CH_3OH), toluene ($\text{C}_6\text{H}_5\text{CH}_3$), and water. Which of these is the best solvent for nonpolar solutes? Explain.

13.30 Would you expect alanine (an amino acid) to be more soluble in water or in hexane? Explain.

Alanine

13.31 (a) Would you expect stearic acid, $\text{CH}_3(\text{CH}_2)_{16}\text{COOH}$, to be more soluble in water or in carbon tetrachloride? Explain.

(b) Which would you expect to be more soluble in water, cyclohexane or dioxane? Explain.

13.32 Ibuprofen, widely used as a pain reliever, has a limited solubility in water, less than 1 mg/mL. Which feature of the molecule contributes to its low solubility in water, and which feature contributes to its solubility?

Ibuprofen

13.33 Which of the following in each pair is likely to be more soluble in hexane, C_6H_{14} : (a) CCl_4 or CaCl_2 ; (b) benzene (C_6H_6) or glycerol, $\text{CH}_2(\text{OH})\text{CH}(\text{OH})\text{CH}_2\text{OH}$; (c) octanoic acid, $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{COOH}$, or acetic acid, CH_3COOH ? Explain your answer in each case.

13.34 Which of the following in each pair is likely to be more soluble in water: (a) cyclohexane (C_6H_{12}) or glucose ($\text{C}_6\text{H}_{12}\text{O}_6$) (Figure 13.12); (b) propionic acid ($\text{CH}_3\text{CH}_2\text{COOH}$) or sodium propionate ($\text{CH}_3\text{CH}_2\text{COONa}$); (c) HCl or ethyl chloride ($\text{CH}_3\text{CH}_2\text{Cl}$)? Explain in each case.

13.35 (a) Explain why carbonated beverages must be stored in sealed containers. (b) Once the beverage has been opened, why does it maintain more carbonation when refrigerated than at room temperature?

13.36 Explain why pressure substantially affects the solubility of O_2 in water but has little effect on the solubility of NaCl in water.

13.37 The Henry's law constant for helium gas in water at 30 °C is $3.7 \times 10^{-4} \text{ M/atm}$ and the constant for N_2 at 30 °C is $6.0 \times 10^{-4} \text{ M/atm}$. If the two gases are each present at 1.5 atm pressure, calculate the solubility of each gas.

13.38 The partial pressure of O_2 in air at sea level is 0.21 atm. Using the data in Table 13.1, together with Henry's law, calculate the molar concentration of O_2 in the surface water of a mountain lake saturated with air at 20 °C and an atmospheric pressure of 650 torr.

CONCENTRATIONS OF SOLUTIONS (section 13.4)

- 13.39** (a) Calculate the mass percentage of Na_2SO_4 in a solution containing 10.6 g Na_2SO_4 in 483 g water. (b) An ore contains 2.86 g of silver per ton of ore. What is the concentration of silver in ppm?
- 13.40** (a) What is the mass percentage of iodine (I_2) in a solution containing 0.035 mol I_2 in 125 g of CCl_4 ? (b) Seawater contains 0.0079 g Sr^{2+} per kilogram of water. What is the concentration of Sr^{2+} measured in ppm?
- 13.41** A solution is made containing 14.6 g of CH_3OH in 184 g H_2O . Calculate (a) the mole fraction of CH_3OH , (b) the mass percent of CH_3OH , (c) the molality of CH_3OH .
- 13.42** A solution is made containing 20.8 g phenol ($\text{C}_6\text{H}_5\text{OH}$) in 425 g ethanol ($\text{C}_2\text{H}_5\text{OH}$). Calculate (a) the mole fraction of phenol, (b) the mass percent of phenol, (c) the molality of phenol.
- 13.43** Calculate the molarity of the following aqueous solutions: (a) 0.540 g $\text{Mg}(\text{NO}_3)_2$ in 250.0 mL of solution, (b) 22.4 g $\text{LiClO}_4 \cdot 3 \text{H}_2\text{O}$ in 125 mL of solution, (c) 25.0 mL of 3.50 M HNO_3 diluted to 0.250 L.
- 13.44** What is the molarity of each of the following solutions: (a) 15.0 g $\text{Al}_2(\text{SO}_4)_3$ in 0.250 mL solution, (b) 5.25 g $\text{Mn}(\text{NO}_3)_2 \cdot 2 \text{H}_2\text{O}$ in 175 mL of solution, (c) 35.0 mL of 9.00 M H_2SO_4 diluted to 0.500 L?
- 13.45** Calculate the molality of each of the following solutions: (a) 8.66 g benzene (C_6H_6) dissolved in 23.6 g carbon tetrachloride (CCl_4), (b) 4.80 g NaCl dissolved in 0.350 L of water.
- 13.46** (a) What is the molality of a solution formed by dissolving 1.12 mol of KCl in 16.0 mol of water? (b) How many grams of sulfur (S_8) must be dissolved in 100.0 g naphthalene (C_{10}H_8) to make a 0.12 *m* solution?
- 13.47** A sulfuric acid solution containing 571.6 g of H_2SO_4 per liter of solution has a density of 1.329 g/cm³. Calculate (a) the mass percentage, (b) the mole fraction, (c) the molality, (d) the molarity of H_2SO_4 in this solution.
- 13.48** Ascorbic acid (vitamin C, $\text{C}_6\text{H}_8\text{O}_6$) is a water-soluble vitamin. A solution containing 80.5 g of ascorbic acid dissolved in 210 g of water has a density of 1.22 g/mL at 55 °C. Calculate (a) the mass percentage, (b) the mole fraction, (c) the molality, (d) the molarity of ascorbic acid in this solution.
- 13.49** The density of acetonitrile (CH_3CN) is 0.786 g/mL and the density of methanol (CH_3OH) is 0.791 g/mL. A solution is made by dissolving 22.5 mL CH_3OH in 98.7 mL CH_3CN . (a) What is the mole fraction of methanol in the solution? (b) What is the molality of the solution? (c) Assuming that the volumes are additive, what is the molarity of CH_3OH in the solution?
- 13.50** The density of toluene (C_7H_8) is 0.867 g/mL, and the density of thiophene ($\text{C}_4\text{H}_4\text{S}$) is 1.065 g/mL. A solution is made by dissolving 8.10 g of thiophene in 250.0 mL of toluene. (a) Calculate the mole fraction of thiophene in the solution. (b) Calculate the molality of thiophene in the solution. (c) Assuming that the volumes of the solute and solvent are additive, what is the molarity of thiophene in the solution?
- 13.51** Calculate the number of moles of solute present in each of the following aqueous solutions: (a) 600 mL of 0.250 M SrBr_2 , (b) 86.4 g of 0.180 *m* KCl , (c) 124.0 g of a solution that is 6.45% glucose ($\text{C}_6\text{H}_{12}\text{O}_6$) by mass.
- 13.52** Calculate the number of moles of solute present in each of the following solutions: (a) 255 mL of 1.50 M $\text{HNO}_3(\text{aq})$, (b) 50.0 mg of an aqueous solution that is 1.50 *m* NaCl , (c) 75.0 g of an aqueous solution that is 1.50% sucrose ($\text{C}_{12}\text{H}_{22}\text{O}_{11}$) by mass.
- 13.53** Describe how you would prepare each of the following aqueous solutions, starting with solid KBr : (a) 0.75 L of 1.5×10^{-2} M KBr , (b) 125 g of 0.180 *m* KBr , (c) 1.85 L of a solution that is 12.0% KBr by mass (the density of the solution is 1.10 g/mL), (d) a 0.150 M solution of KBr that contains just enough KBr to precipitate 16.0 g of AgBr from a solution containing 0.480 mol of AgNO_3 .
- 13.54** Describe how you would prepare each of the following aqueous solutions: (a) 1.50 L of 0.110 M $(\text{NH}_4)_2\text{SO}_4$ solution, starting with solid $(\text{NH}_4)_2\text{SO}_4$; (b) 225 g of a solution that is 0.65 *m* in Na_2CO_3 , starting with the solid solute; (c) 1.20 L of a solution that is 15.0% $\text{Pb}(\text{NO}_3)_2$ by mass (the density of the solution is 1.16 g/mL), starting with solid solute; (d) a 0.50 M solution of HCl that would just neutralize 5.5 g of $\text{Ba}(\text{OH})_2$ starting with 6.0 M HCl .
- 13.55** Commercial aqueous nitric acid has a density of 1.42 g/mL and is 16 M. Calculate the percent HNO_3 by mass in the solution.
- 13.56** Commercial concentrated aqueous ammonia is 28% NH_3 by mass and has a density of 0.90 g/mL. What is the molarity of this solution?
- 13.57** Brass is a substitutional alloy consisting of a solution of copper and zinc. A particular sample of red brass consisting of 80.0% Cu and 20.0% Zn by mass has a density of 8750 kg/m³. (a) What is the molality of Zn in the solid solution? (b) What is the molarity of Zn in the solution?
- 13.58** Caffeine ($\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2$) is a stimulant found in coffee and tea. If a solution of caffeine in chloroform (CHCl_3) as a solvent has a concentration of 0.0500 *m*, calculate (a) the percent caffeine by mass, (b) the mole fraction of caffeine.

Caffeine

- 13.59** During a typical breathing cycle, the CO_2 concentration in the expired air rises to a peak of 4.6% by volume. Calculate the partial pressure of the CO_2 at this point, assuming 1 atm pressure. What is the molarity of the CO_2 in air at this point, assuming a body temperature of 37 °C?
- 13.60** Breathing air that contains 4.0% by volume CO_2 over time causes rapid breathing, throbbing headache, and nausea, among other symptoms. What is the concentration of CO_2 in such air in terms of (a) mol percentage, (b) molarity, assuming 1 atm pressure and a body temperature of 37 °C?

COLLIGATIVE PROPERTIES (section 13.5)

- 13.61** List four properties of a solution that depend on the total concentration but not the type of particle or particles present as solute. Write the mathematical expression that describes how each of these properties depends on concentration.
- 13.62** How does increasing the concentration of a nonvolatile solute in water affect the following properties: (a) vapor pressure, (b) freezing point, (c) boiling point; (d) osmotic pressure?
- 13.63** Consider two solutions, one formed by adding 10 g of glucose ($C_6H_{12}O_6$) to 1 L of water and the other formed by adding 10 g of sucrose ($C_{12}H_{22}O_{11}$) to 1 L of water. Are the vapor pressures over the two solutions the same? Why or why not?
- 13.64** (a) What is an *ideal solution*? (b) The vapor pressure of pure water at 60 °C is 149 torr. The vapor pressure of water over a solution at 60 °C containing equal numbers of moles of water and ethylene glycol (a nonvolatile solute) is 67 torr. Is the solution ideal according to Raoult's law? Explain.
- 13.65** (a) Calculate the vapor pressure of water above a solution prepared by adding 22.5 g of lactose ($C_{12}H_{22}O_{11}$) to 200.0 g of water at 338 K. (Vapor-pressure data for water are given in Appendix B.) (b) Calculate the mass of propylene glycol ($C_3H_8O_2$) that must be added to 0.340 kg of water to reduce the vapor pressure by 2.88 torr at 40 °C.
- 13.66** (a) Calculate the vapor pressure of water above a solution prepared by dissolving 28.5 g of glycerin ($C_3H_8O_3$) in 125 g of water at 343 K. (The vapor pressure of water is given in Appendix B.) (b) Calculate the mass of ethylene glycol ($C_2H_6O_2$) that must be added to 1.00 kg of ethanol (C_2H_5OH) to reduce its vapor pressure by 10.0 torr at 35 °C. The vapor pressure of pure ethanol at 35 °C is 1.00×10^2 torr.
- [13.67]** At 63.5 °C the vapor pressure of H_2O is 175 torr, and that of ethanol (C_2H_5OH) is 400 torr. A solution is made by mixing equal masses of H_2O and C_2H_5OH . (a) What is the mole fraction of ethanol in the solution? (b) Assuming ideal-solution behavior, what is the vapor pressure of the solution at 63.5 °C? (c) What is the mole fraction of ethanol in the vapor above the solution?
- [13.68]** At 20 °C the vapor pressure of benzene (C_6H_6) is 75 torr, and that of toluene (C_7H_8) is 22 torr. Assume that benzene and toluene form an ideal solution. (a) What is the composition in mole fractions of a solution that has a vapor pressure of 35 torr at 20 °C? (b) What is the mole fraction of benzene in the vapor above the solution described in part (a)?
- 13.69** (a) Why does a 0.10 *m* aqueous solution of NaCl have a higher boiling point than a 0.10 *m* aqueous solution of $C_6H_{12}O_6$? (b) Calculate the boiling point of each solution. (c) The experimental boiling point of the NaCl solution is lower than that calculated, assuming that NaCl is completely dissociated in solution. Why is this the case?
- 13.70** Arrange the following aqueous solutions, each 10% by mass in solute, in order of increasing boiling point: glucose ($C_6H_{12}O_6$), sucrose ($C_{12}H_{22}O_{11}$), sodium nitrate ($NaNO_3$).
- 13.71** List the following aqueous solutions in order of increasing boiling point: 0.120 *m* glucose, 0.050 *m* LiBr, 0.050 *m* $Zn(NO_3)_2$.
- 13.72** List the following aqueous solutions in order of decreasing freezing point: 0.040 *m* glycerin ($C_3H_8O_3$), 0.020 *m* KBr, 0.030 *m* phenol (C_6H_5OH).
- 13.73** Using data from Table 13.3, calculate the freezing and boiling points of each of the following solutions: (a) 0.22 *m* glycerol ($C_3H_8O_3$) in ethanol, (b) 0.240 mol of naphthalene ($C_{10}H_8$) in 2.45 mol of chloroform, (c) 1.50 g NaCl in 0.250 kg of water, (d) 2.04 g KBr and 4.82 g glucose ($C_6H_{12}O_6$) in 188 g of water.
- 13.74** Using data from Table 13.3, calculate the freezing and boiling points of each of the following solutions: (a) 0.25 *m* glucose in ethanol; (b) 20.0 g of decane, $C_{10}H_{22}$, in 50.0 g $CHCl_3$; (c) 3.50 g NaOH in 175 g of water, (d) 0.45 mol ethylene glycol and 0.15 mol KBr in 150 g H_2O .
- 13.75** How many grams of ethylene glycol ($C_2H_6O_2$) must be added to 1.00 kg of water to produce a solution that freezes at -5.00 °C?
- 13.76** What is the freezing point of an aqueous solution that boils at 105.0 °C?
- 13.77** What is the osmotic pressure formed by dissolving 44.2 mg of aspirin ($C_9H_8O_4$) in 0.358 L of water at 25 °C?
- 13.78** Seawater contains 3.4 g of salts for every liter of solution. Assuming that the solute consists entirely of NaCl (over 90% is), calculate the osmotic pressure of seawater at 20 °C.
- 13.79** Adrenaline is the hormone that triggers the release of extra glucose molecules in times of stress or emergency. A solution of 0.64 g of adrenaline in 36.0 g of CCl_4 elevates the boiling point by 0.49 °C. Is the molar mass of adrenaline calculated from the boiling-point elevation in agreement with the following structural formula?

Adrenaline

13.80 Lauryl alcohol is obtained from coconut oil and is used to make detergents. A solution of 5.00 g of lauryl alcohol in 0.100 kg of benzene freezes at 4.1 °C. What is the approximate molar mass of lauryl alcohol?

13.81 Lysozyme is an enzyme that breaks bacterial cell walls. A solution containing 0.150 g of this enzyme in 210 mL of solution has an osmotic pressure of 0.953 torr at 25 °C. What is the molar mass of lysozyme?

13.82 A dilute aqueous solution of an organic compound soluble in water is formed by dissolving 2.35 g of the compound in water to form 0.250 L of solution. The resulting solution has an osmotic pressure of 0.605 atm at 25 °C. Assuming that the organic compound is a nonelectrolyte, what is its molar mass?

[13.83] The osmotic pressure of a 0.010 *M* aqueous solution of $CaCl_2$ is found to be 0.674 atm at 25 °C. (a) Calculate the van't Hoff factor, *i*, for the solution. (b) How would you expect the value of *i* to change as the solution becomes more concentrated? Explain.

[13.84] Based on the data given in Table 13.4, which solution would give the larger freezing-point lowering, a 0.030 *m* solution of NaCl or a 0.020 *m* solution of K_2SO_4 ? How do you explain the departure from ideal behavior and the differences observed between the two salts?

COLLOIDS (section 13.6)

- 13.85** (a) Why is there no colloid in which both the dispersed substance and the dispersing substance are gases? (b) Michael Faraday first prepared ruby-red colloids of gold particles in water that were stable indefinitely. To the unaided eye these brightly colored colloids are not distinguishable from solutions. How could you determine whether a given colored preparation is a solution or colloid?
- 13.86** (a) Many proteins that remain homogeneously distributed in water have molecular masses in the range of 30,000 amu and larger. In what sense is it appropriate to consider such suspensions to be colloids rather than solutions? Explain. (b) What general name is given to a colloidal dispersion of one liquid in another? What is an emulsifying agent?
- 13.87** Indicate whether each of the following is a hydrophilic or a hydrophobic colloid: (a) butterfat in homogenized milk, (b) hemoglobin in blood, (c) vegetable oil in a salad dressing, (d) colloidal gold particles in water.
- 13.88** Explain how each of the following factors helps determine the stability or instability of a colloidal dispersion: (a) particulate mass, (b) hydrophobic character, (c) charges on colloidal particles.
- 13.89** Colloidal dispersions of proteins, such as a gelatin, can often be caused to separate into two layers by addition of a solution of an electrolyte. Given that protein molecules may carry electrical charges on their outer surface as illustrated in Figure 13.30, what do you believe happens when the electrolyte solution is added?
- 13.90** Explain how (a) a soap such as sodium stearate stabilizes a colloidal dispersion of oil droplets in water; (b) milk curdles upon addition of an acid.

ADDITIONAL EXERCISES

- 13.91** Butylated hydroxytoluene (BHT) has the following molecular structure:

It is widely used as a preservative in a variety of foods, including dried cereals. Based on its structure, would you expect BHT to be more soluble in water or in hexane (C_6H_{14})? Explain.

- 13.92** A saturated solution of sucrose ($C_{12}H_{22}O_{11}$) is made by dissolving excess table sugar in a flask of water. There are 50 g of undissolved sucrose crystals at the bottom of the flask in contact with the saturated solution. The flask is stoppered and set aside. A year later a single large crystal of mass 50 g is at the bottom of the flask. Explain how this experiment provides evidence for a dynamic equilibrium between the saturated solution and the undissolved solute.
- 13.93** Most fish need at least 4 ppm dissolved O_2 for survival. (a) What is this concentration in mol/L? (b) What partial pressure of O_2 above the water is needed to obtain this concentration at $10^\circ C$? (The Henry's law constant for O_2 at this temperature is 1.71×10^{-3} mol/L-atm.)
- 13.94** The presence of the radioactive gas radon (Rn) in well water obtained from aquifers that lie in rock deposits presents a possible health hazard in parts of the United States. (a) Assuming that the solubility of radon in water with 1 atm pressure of the gas over the water at $30^\circ C$ is $7.27 \times 10^{-3} M$, what is the Henry's law constant for radon in water at this temperature? (b) A sample consisting of various gases contains 3.5×10^{-6} mole fraction of radon. This gas at a total pressure of 32 atm is shaken with water at $30^\circ C$. Calculate the molar concentration of radon in the water.
- 13.95** Glucose makes up about 0.10% by mass of human blood. Calculate the concentration in (a) ppm, (b) molality. What further information would you need to determine the molarity of the solution?
- 13.96** The concentration of gold in seawater has been reported to be between 5 ppt (parts per trillion) and 50 ppt. Assuming that seawater contains 13 ppt of gold, calculate the number of grams of gold contained in 1.0×10^3 gal of seawater.
- 13.97** The maximum allowable concentration of lead in drinking water is 9.0 ppb. (a) Calculate the molarity of lead in a 9.0-ppb solution. What assumption did you have to make in your calculation? (b) How many grams of lead are in a swimming pool containing 9.0 ppb lead in $60 m^3$ of water?
- 13.98** Acetonitrile (CH_3CN) is a polar organic solvent that dissolves a wide range of solutes, including many salts. The density of a 1.80 M LiBr solution in acetonitrile is $0.826 g/cm^3$. Calculate the concentration of the solution in (a) molality, (b) mole fraction of LiBr, (c) mass percentage of CH_3CN .
- 13.99** A "canned heat" product used to warm chafing dishes consists of a homogeneous mixture of ethanol (C_2H_5OH) and paraffin that has an average formula of $C_{24}H_{50}$. What mass of C_2H_5OH should be added to 620 kg of the paraffin in formulating the mixture if the vapor pressure of ethanol at $35^\circ C$ over the mixture is to be 8 torr? The vapor pressure of pure ethanol at $35^\circ C$ is 100 torr.
- 13.100** A solution contains 0.115 mol H_2O and an unknown number of moles of sodium chloride. The vapor pressure of the solution at $30^\circ C$ is 25.7 torr. The vapor pressure of pure water at this temperature is 31.8 torr. Calculate the number of moles of sodium chloride in the solution. (*Hint*: Remember that sodium chloride is a strong electrolyte.)
- [13.101]** Two beakers are placed in a sealed box at $25^\circ C$. One beaker contains 30.0 mL of a 0.050 M aqueous solution of a non-volatile nonelectrolyte. The other beaker contains 30.0 mL of a 0.035 M aqueous solution of NaCl. The water vapor from the two solutions reaches equilibrium. (a) In which beaker does the solution level rise, and in which one does it fall? (b) What are the volumes in the two beakers when equilibrium is attained, assuming ideal behavior?
- 13.102** A car owner who knows no chemistry has to put antifreeze in his car's radiator. The instructions recommend a mixture of 30% ethylene glycol and 70% water. Thinking he will improve his protection he uses pure ethylene glycol. He is saddened to find that the solution does not provide as much protection as he hoped. Why not?

- 13.103** Calculate the freezing point of a 0.100 *m* aqueous solution of K_2SO_4 , (a) ignoring interionic attractions, and (b) taking interionic attractions into consideration by using the van't Hoff factor (Table 13.4).
- 13.104** Carbon disulfide (CS_2) boils at 46.30 °C and has a density of 1.261 g/mL. (a) When 0.250 mol of a nondissociating solute is dissolved in 400.0 mL of CS_2 , the solution boils at 47.46 °C. What is the molal boiling-point-elevation constant for CS_2 ? (b) When 5.39 g of a nondissociating unknown is dissolved

in 50.0 mL of CS_2 , the solution boils at 47.08 °C. What is the molecular weight of the unknown?

- [13.105]** A lithium salt used in lubricating grease has the formula $LiC_nH_{2n+1}O_2$. The salt is soluble in water to the extent of 0.036 g per 100 g of water at 25 °C. The osmotic pressure of this solution is found to be 57.1 torr. Assuming that molality and molarity in such a dilute solution are the same and that the lithium salt is completely dissociated in the solution, determine an appropriate value of *n* in the formula for the salt.

INTEGRATIVE EXERCISES

- 13.106** Fluorocarbons (compounds that contain both carbon and fluorine) were, until recently, used as refrigerants. The compounds listed in the following table are all gases at 25 °C, and their solubilities in water at 25 °C and 1 atm fluorocarbon pressure are given as mass percentages. (a) For each fluorocarbon, calculate the molality of a saturated solution. (b) Explain why the molarity of each of the solutions should be very close numerically to the molality. (c) Based on their molecular structures, account for the differences in solubility of the four fluorocarbons. (d) Calculate the Henry's law constant at 25 °C for $CHClF_2$, and compare its magnitude to that for N_2 (6.8×10^{-4} mol/L-atm). Can you account for the difference in magnitude?

Fluorocarbon	Solubility (mass %)
CF_4	0.0015
$CClF_3$	0.009
CCl_2F_2	0.028
$CHClF_2$	0.30

- [13.107]** At ordinary body temperature (37 °C) the solubility of N_2 in water in contact with air at ordinary atmospheric pressure (1.0 atm) is 0.015 g/L. Air is approximately 78 mol % N_2 . Calculate the number of moles of N_2 dissolved per liter of blood, which is essentially an aqueous solution. At a depth of 100 ft in water, the pressure is 4.0 atm. What is the solubility of N_2 from air in blood at this pressure? If a scuba diver suddenly surfaces from this depth, how many milliliters of N_2 gas, in the form of tiny bubbles, are released into the bloodstream from each liter of blood?
- [13.108]** Consider the following values for enthalpy of vaporization (kJ/mol) of several organic substances:

Acetaldehyde

Ethylene oxide

(a) Use variations in the intermolecular forces operating in these organic substances to account for their variations in heats of vaporization. (b) How would you expect the solubilities of these substances to vary in hexane as solvent? In ethanol? Use intermolecular forces, including hydrogen-bonding interactions where applicable, to explain your responses.

- [13.109]** A textbook on chemical thermodynamics states, "The heat of solution represents the difference between the lattice energy of the crystalline solid and the solvation energy of the gaseous ions." (a) Draw a simple energy diagram to illustrate this statement. (b) A salt such as NaBr is insoluble in most polar nonaqueous solvents such as acetonitrile (CH_3CN) or nitromethane (CH_3NO_2), but salts of large cations, such as tetramethylammonium bromide [$(CH_3)_4NBr$], are generally more soluble. Use the thermochemical cycle you drew in part (a) and the factors that determine the lattice energy (Section 8.2) to explain this fact.

- 13.110** (a) A sample of hydrogen gas is generated in a closed container by reacting 2.050 g of zinc metal with 15.0 mL of 1.00 *M* sulfuric acid. Write the balanced equation for the reaction, and calculate the number of moles of hydrogen formed, assuming that the reaction is complete. (b) The volume over the solution is 122 mL. Calculate the partial pressure of the hydrogen gas in this volume at 25 °C, ignoring any solubility of the gas in the solution. (c) The Henry's law constant for hydrogen in water at 25 °C is 7.8×10^{-4} mol/L-atm. Estimate the number of moles of hydrogen gas that remain dissolved in the solution. What fraction of the gas molecules in the system is dissolved in the solution? Was it reasonable to ignore any dissolved hydrogen in part (b)?

- [13.111] The following table presents the solubilities of several gases in water at 25 °C under a total pressure of gas and water vapor of 1 atm. (a) What volume of $\text{CH}_4(g)$ under standard conditions of temperature and pressure is contained in 4.0 L of a saturated solution at 25 °C? (b) Explain the variation in solubility among the hydrocarbons listed (the first three compounds), based on their molecular structures and intermolecular forces. (c) Compare the solubilities of O_2 , N_2 , and NO , and account for the variations based on molecular structures and intermolecular forces. (d) Account for the much larger values observed for H_2S and SO_2 as compared with the other gases listed. (e) Find several pairs of substances with the same or nearly the same molecular masses (for example, C_2H_4 and N_2), and use intermolecular interactions to explain the differences in their solubilities.

Gas	Solubility (mM)
CH_4 (methane)	1.3
C_2H_6 (ethane)	1.8
C_2H_4 (ethylene)	4.7
N_2	0.6
O_2	1.2
NO	1.9
H_2S	99
SO_2	1476

- 13.112 A small cube of lithium (density = 0.535 g/cm^3) measuring 1.0 mm on each edge is added to 0.500 L of water. The following reaction occurs:

What is the freezing point of the resultant solution?

- [13.113] At 35 °C the vapor pressure of acetone, $(\text{CH}_3)_2\text{CO}$, is 360 torr, and that of chloroform, CHCl_3 , is 300 torr. Acetone and chloroform can form very weak hydrogen bonds between one another as follows:

A solution composed of an equal number of moles of acetone and chloroform has a vapor pressure of 250 torr at 35 °C. (a) What would be the vapor pressure of the solution if it exhibited ideal behavior? (b) Use the existence of hydrogen bonds between acetone and chloroform molecules to explain the deviation from ideal behavior. (c) Based on the behavior of the solution, predict whether the mixing of acetone and chloroform is an exothermic ($\Delta H_{\text{soln}} < 0$) or endothermic ($\Delta H_{\text{soln}} > 0$) process.

WHAT'S AHEAD

14.1 FACTORS THAT AFFECT REACTION RATES

We explore four variables that affect reaction rates: concentration, physical states of reactants, temperature, and presence of catalysts. These factors can be understood in terms of the collisions among reactant molecules that lead to reaction.

14.2 REACTION RATES

We consider how to express *reaction rates* and how reactant disappearance rates and product appearance rates are related to the reaction stoichiometry.

14.3 CONCENTRATION AND RATE LAWS

We then show that the effect of concentration on rate is expressed quantitatively by *rate laws* and show how rate laws and *rate constants* are determined experimentally.

14.4 THE CHANGE OF CONCENTRATION WITH TIME

We learn that rate equations can be written to express how concentrations change with time and look at several examples of rate equations: *zero-order*, *first-order*, and *second-order* reactions.

THE BELOUSOV-ZHABOTINSKY REACTION is one of the most famous reactions in the chemical world. The swirls of colors correspond to products forming at different places and times in the unstirred petri dish.

14.5 TEMPERATURE AND RATE

We next consider the effect of temperature on rate. In order to occur, most reactions require a minimum input of energy called the *activation energy*.

14.6 REACTION MECHANISMS

We then examine *reaction mechanisms*, the step-by-step molecular pathways leading from reactants to products.

14.7 CATALYSIS

We end the chapter with a discussion of how *catalysts* increase reaction rates, including a discussion of biological catalysts called *enzymes*.

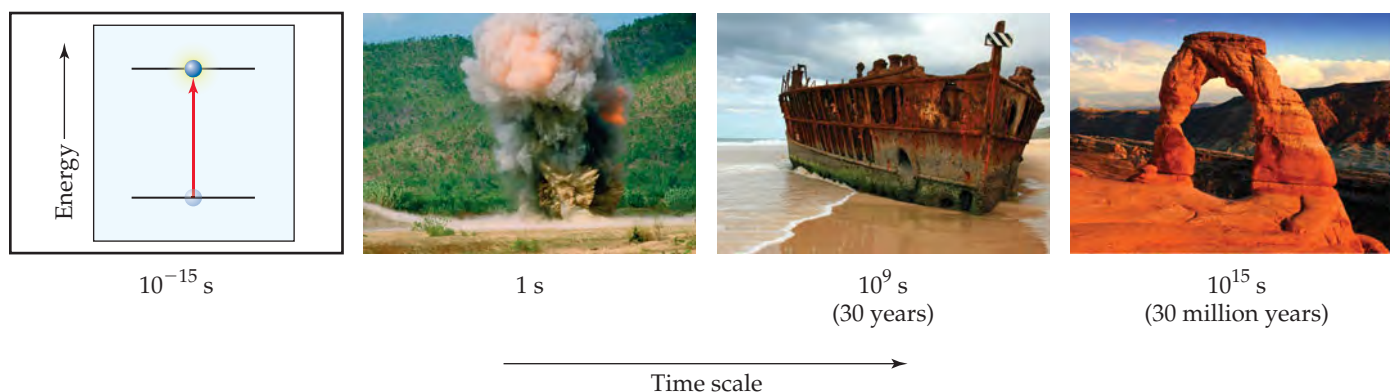

CHEMICAL KINETICS

CHEMICAL REACTIONS CONVERT SUBSTANCES that have well-defined properties into other substances that have different properties. The chapter-opening photograph, for instance, shows that we can watch complex reactions as they happen in time by observing the different colors of reactants and products.

In this particular case, multiple redox reactions are occurring, with the products of one reaction becoming the reactants in other reactions.

So far, we have been concerned with the beginning and end of chemical reactions: We start with certain reactants and see what products they yield. This view is useful but does not tell us what happens in the middle, that is, which chemical bonds are broken, which are formed, and in what order these events occur. The speed at which a chemical reaction occurs is called the **reaction rate**. To investigate how reactions happen, we must examine the reaction rates and the factors that influence them. Experimental information on the rate of a given reaction provides important evidence that helps us formulate a *reaction mechanism*, which is a step-by-step, molecular-level view of the pathway from reactants to products.

Some chemical reactions are complete within a fraction of a second, such as explosions, whereas others can take thousands or even millions of years, such as the formation of minerals in Earth's crust (► **FIGURE 14.1**).

▲ **FIGURE 14.1** Reaction rates span an enormous range of time scales. The absorption of light by an atom or molecule is complete within one femtosecond; explosions occur within seconds; corrosion can occur over years; and the weathering of rocks can occur over millions of years.

Steel wool heated in air (about 20% O_2) glows red-hot but oxidizes to Fe_2O_3 slowly

Red-hot steel wool in 100% O_2 burns vigorously, forming Fe_2O_3 quickly

▲ **FIGURE 14.2** Effect of concentration on reaction rate. The difference in behavior is due to the different concentrations of O_2 in the two environments.

The area of chemistry concerned with the speeds, or rates, of reactions is **chemical kinetics**. Chemical kinetics relates to how quickly a medicine works in the body, to whether the processes that form and deplete ozone in the atmosphere are in balance, and to such industrial challenges as the development of new *catalysts*, materials that speed up reactions.

Our goal in this chapter is to understand how to determine reaction rates and to consider the factors that control these rates. What factors determine how rapidly food spoils, for instance, or how does one design a fast-setting material for dental fillings? What determines the rate at which steel rusts, or how can we remove hazardous pollutants in automobile exhaust before the exhaust leaves the tailpipe? Although we will not address these specific questions, we will see that the rates of all chemical reactions are subject to the same principles.

14.1 FACTORS THAT AFFECT REACTION RATES

Four factors allow us to change the rate at which any particular reaction occurs:

- 1. Physical state of the reactants.** Reactants must come together to react. The more readily reactant molecules collide with one another, the more rapidly they react. Most of the reactions we consider are homogeneous, involving either all gases or all liquids. When reactants are in different phases, however, we have heterogeneous conditions, and the reaction is limited by the area of contact of the reactants. Thus, heterogeneous reactions that involve solids tend to proceed faster if the surface area of the solid is increased. For example, a medicine in the form of a fine powder dissolves in the stomach and enters the blood more quickly than the same medicine in the form of a tablet.
- 2. Reactant concentrations.** Most chemical reactions proceed faster if the concentration of one or more reactants is increased. For example, steel wool burns only slowly in air, which contains 20% O_2 , but bursts into flame in pure oxygen (◀ **FIGURE 14.2**). As reactant concentration increases, the frequency with which the reactant molecules collide increases, leading to increased rates.
- 3. Reaction temperature.** Reaction rates generally increase as temperature is increased. The bacterial reactions that spoil milk, for instance, proceed more rapidly at room temperature than at the lower temperature of a refrigerator. Increasing temperature increases the kinetic energies of molecules. ∞ (Section 10.7) As molecules move more rapidly, they collide more frequently and with higher energy, leading to increased reaction rates.

4. The presence of a catalyst. *Catalysts* are agents that increase reaction rates without themselves being used up. They affect the kinds of collisions (and therefore alter the mechanism) that lead to reaction. Catalysts play many crucial roles in living organisms, including ourselves.

On a molecular level, reaction rates depend on the frequency of collisions between molecules. The greater the frequency of collisions, the higher the reaction rate. For a collision to lead to a reaction, however, it must occur with sufficient energy to break bonds and with suitable orientation for new bonds to form in the proper locations. We will consider these factors as we proceed through this chapter.

GIVE IT SOME THOUGHT

In a reaction involving reactants in the gas state, how does increasing the partial pressures of the gases affect the reaction rate?

14.2 REACTION RATES

The *speed* of an event is defined as the *change* that occurs in a given *time* interval, which means that whenever we talk about speed, we necessarily bring in the notion of time. For example, the speed of a car is expressed as the change in the car's position over a certain time interval. The units of this speed are usually miles per hour—that is, the quantity that is changing (position measured in miles) divided by a time interval (measured in hours).

Similarly, the speed of a chemical reaction—its reaction rate—is the change in the concentration of reactants or products per unit of time. The units for reaction rate are usually molarity per second (M/s)—that is, the change in concentration measured in molarity divided by a time interval measured in seconds.

Let's consider the hypothetical reaction $A \longrightarrow B$, depicted in  **FIGURE 14.3**. Each red sphere represents 0.01 mol of A, each blue sphere represents 0.01 mol of B, and the container has a volume of 1.00 L. At the beginning of the reaction, there is 1.00 mol A, so the concentration is $1.00 \text{ mol/L} = 1.00 \text{ M}$. After 20 s the concentration of A has fallen to 0.54 M and the concentration of B has risen to 0.46 M . The sum of the concentrations is still 1.00 M because 1 mol of B is produced for each mole of A that reacts. After 40 s the concentration of A is 0.30 M and that of B is 0.70 M .

GO FIGURE

If A converts completely to B, what type of molecules will the container hold?

 **FIGURE 14.3** Progress of a hypothetical reaction $A \longrightarrow B$.

The rate of this reaction can be expressed either as the rate of disappearance of reactant A or as the rate of appearance of product B. The *average* rate of appearance of B over a particular time interval is given by the change in concentration of B divided by the change in time:

$$\begin{aligned}\text{Average rate of appearance of B} &= \frac{\text{change in concentration of B}}{\text{change in time}} \\ &= \frac{[\text{B}] \text{ at } t_2 - [\text{B}] \text{ at } t_1}{t_2 - t_1} = \frac{\Delta[\text{B}]}{\Delta t} \quad [14.1]\end{aligned}$$

We use brackets around a chemical formula, as in [B], to indicate molarity. The Greek letter delta, Δ , is read “change in” and is always equal to a final value minus an initial value. ∞ (Section 5.2) The average rate of appearance of B over the 20-s interval from the beginning of the reaction ($t_1 = 0$ s to $t_2 = 20$ s) is

$$\text{Average rate} = \frac{0.46 \text{ M} - 0.00 \text{ M}}{20 \text{ s} - 0 \text{ s}} = 2.3 \times 10^{-2} \text{ M/s}$$

We could equally well express the reaction rate in term of the reactant, A. In this case we would be describing the rate of disappearance of A, which we express as

$$\begin{aligned}\text{Average rate of disappearance of A} &= -\frac{\text{change in concentration of A}}{\text{change in time}} \\ &= -\frac{\Delta[\text{A}]}{\Delta t} \quad [14.2]\end{aligned}$$

Notice the minus sign in this equation, which we use to indicate that the concentration of A decreases. By convention, *rates are always expressed as positive quantities*. Because [A] decreases, $\Delta[\text{A}]$ is a negative number. The minus sign we put in the equation converts the negative $\Delta[\text{A}]$ to a positive rate of disappearance.

Because one molecule of A is consumed for every molecule of B that forms, the average rate of disappearance of A equals the average rate of appearance of B:

$$\text{Average rate} = -\frac{\Delta[\text{A}]}{\Delta t} = -\frac{0.54 \text{ M} - 1.00 \text{ M}}{20 \text{ s} - 0 \text{ s}} = 2.3 \times 10^{-2} \text{ M/s}$$

SAMPLE EXERCISE 14.1 Calculating an Average Rate of Reaction

From the data in Figure 14.3, calculate the average rate at which A disappears over the time interval from 20 s to 40 s.

SOLUTION

Analyze We are given the concentration of A at 20 s (0.54 M) and at 40 s (0.30 M) and asked to calculate the average rate of reaction over this time interval.

Plan The average rate is given by the change in concentration, $\Delta[\text{A}]$, divided by the change in time, Δt . Because A is a reactant, a minus sign is used in the calculation to make the rate a positive quantity.

$$\text{Solve} \quad \text{Average rate} = -\frac{\Delta[\text{A}]}{\Delta t} = -\frac{0.30 \text{ M} - 0.54 \text{ M}}{40 \text{ s} - 20 \text{ s}} = 1.2 \times 10^{-2} \text{ M/s}$$

PRACTICE EXERCISE

Use the data in Figure 14.3 to calculate the average rate of appearance of B over the time interval from 0 s to 40 s.

Answer: $1.8 \times 10^{-2} \text{ M/s}$

TABLE 14.1 • Rate Data for Reaction of C₄H₉Cl with Water

Time, <i>t</i> (s)	[C ₄ H ₉ Cl](<i>M</i>)	Average Rate (<i>M</i> /s)
0.0	0.1000	1.9 × 10 ⁻⁴
50.0	0.0905	1.7 × 10 ⁻⁴
100.0	0.0820	1.6 × 10 ⁻⁴
150.0	0.0741	1.4 × 10 ⁻⁴
200.0	0.0671	1.22 × 10 ⁻⁴
300.0	0.0549	1.01 × 10 ⁻⁴
400.0	0.0448	0.80 × 10 ⁻⁴
500.0	0.0368	0.560 × 10 ⁻⁴
800.0	0.0200	
10,000	0	

Change of Rate with Time

Now let's consider the reaction between butyl chloride (C₄H₉Cl) and water to form butyl alcohol (C₄H₉OH) and hydrochloric acid:

Suppose we prepare a 0.1000-*M* aqueous solution of C₄H₉Cl and then measure the concentration of C₄H₉Cl at various times after time zero (which is the instant at which the reactants are mixed, thereby initiating the reaction). We can use the resulting data, shown in the first two columns of **TABLE 14.1**, to calculate the average rate of disappearance of C₄H₉Cl over various time intervals; these rates are given in the third column. Notice that the average rate decreases over each 50-s interval for the first several measurements and continues to decrease over even larger intervals through the remaining measurements. *It is typical for rates to decrease as a reaction proceeds because the concentration of reactants decreases.* The change in rate as the reaction proceeds is also seen in a graph of [C₄H₉Cl] versus time (**FIGURE 14.4**). Notice how the steepness of the curve decreases with time, indicating a decreasing reaction rate.

Instantaneous Rate

Graphs showing how the concentration of a reactant or product changes with time, such as Figure 14.4, allow us to evaluate the **instantaneous rate** of a reaction, which is the rate at a particular instant during the reaction. The instantaneous rate is determined from the slope of the curve at a particular point in time. We have drawn two tangent lines in Figure 14.4, a dashed line running through the point at *t* = 0 s and a solid line running through the point at *t* = 600 s. The slopes of these tangent lines give the instantaneous rates at these two time points.* To determine the instantaneous rate at 600 s, we construct horizontal and vertical lines to form the blue right triangle in Figure 14.4. The slope of the tangent line is the ratio of the height of the vertical side to the length of the horizontal side:

$$\begin{aligned} \text{Instantaneous rate} &= -\frac{\Delta[\text{C}_4\text{H}_9\text{Cl}]}{\Delta t} = -\frac{(0.017 - 0.042) \text{ M}}{(800 - 400) \text{ s}} \\ &= 6.3 \times 10^{-5} \text{ M/s} \end{aligned}$$

*You may wish to review graphical determination of slopes in Appendix A. If you are familiar with calculus, you may recognize that the average rate approaches the instantaneous rate as the time interval approaches zero. This limit, in the notation of calculus, is represented as $-d[\text{C}_4\text{H}_9\text{Cl}]/dt$.

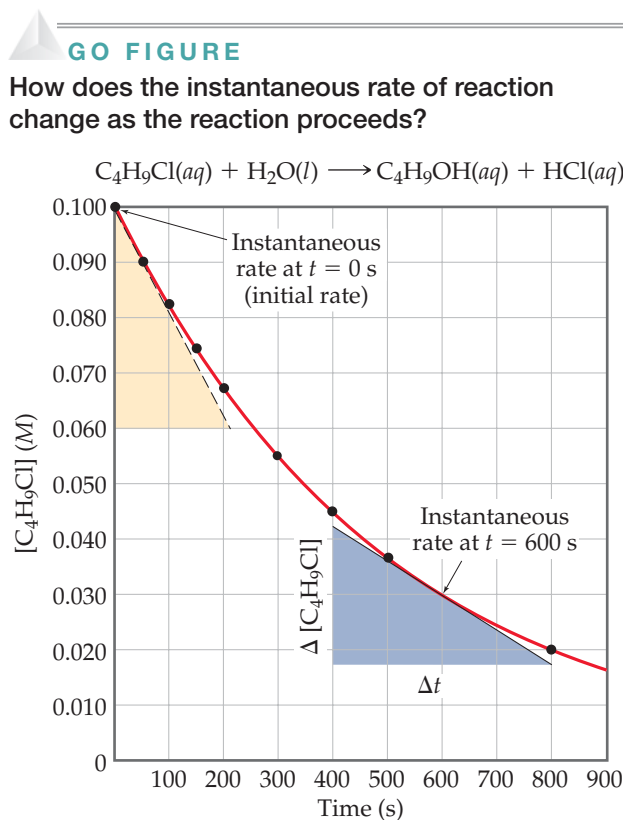

FIGURE 14.4 Concentration of butyl chloride (C₄H₉Cl) as a function of time.

In discussions that follow, the term *rate* means instantaneous rate unless indicated otherwise. The instantaneous rate at $t = 0$ is called the *initial rate* of the reaction. To understand the difference between average and instantaneous rates, imagine you have just driven 98 mi in 2.0 hr. Your average speed for the trip is 49 mi/hr, but your instantaneous speed at any moment during the trip is the speedometer reading at that moment.

SAMPLE EXERCISE 14.2 Calculating an Instantaneous Rate of Reaction

Using Figure 14.4, calculate the instantaneous rate of disappearance of C_4H_9Cl at $t = 0$ s (the initial rate).

SOLUTION

Analyze We are asked to determine an instantaneous rate from a graph of reactant concentration versus time.

Plan To obtain the instantaneous rate at $t = 0$ s, we must determine the slope of the curve at $t = 0$. The tangent is drawn on the graph as the hypotenuse of the tan triangle. The slope of this straight line equals the change in the vertical axis divided by the corresponding change in the horizontal axis (that is, change in molarity over change in time).

Solve The tangent line falls from $[C_4H_9Cl] = 0.100$ M to 0.060 M in the time change from 0 s to 210 s. Thus, the initial rate is

$$\text{Rate} = -\frac{\Delta[C_4H_9Cl]}{\Delta t} = -\frac{(0.060 - 0.100) \text{ M}}{(210 - 0) \text{ s}} = 1.9 \times 10^{-4} \text{ M/s}$$

PRACTICE EXERCISE

Using Figure 14.4, determine the instantaneous rate of disappearance of C_4H_9Cl at $t = 300$ s.

Answer: $1.1 \times 10^{-4} \text{ M/s}$

GIVE IT SOME THOUGHT

What is the difference between average rate and instantaneous rate? In a given reaction, can these two rates ever have the same numeric value?

Reaction Rates and Stoichiometry

During our discussion of the hypothetical reaction $A \longrightarrow B$, we saw that the stoichiometry requires that the rate of disappearance of A equal the rate of appearance of B. Likewise, the stoichiometry of Equation 14.3 indicates that 1 mol of C_4H_9OH is produced for each mole of C_4H_9Cl consumed. Therefore, the rate of appearance of C_4H_9OH equals the rate of disappearance of C_4H_9Cl :

$$\text{Rate} = -\frac{\Delta[C_4H_9Cl]}{\Delta t} = \frac{\Delta[C_4H_9OH]}{\Delta t}$$

What happens when the stoichiometric relationships are not one-to-one? For example, consider the reaction $2 \text{HI}(g) \rightarrow \text{H}_2(g) + \text{I}_2(g)$. We can measure either the rate of disappearance of HI or the rate of appearance of either H_2 or I_2 . Because 2 mol of HI disappear for each mole of H_2 or I_2 that forms, the rate of disappearance of HI is twice the rate of appearance of either H_2 or I_2 . How do we decide which number to use for the rate of the reaction? Depending on whether we monitor HI, I_2 , or H_2 , the rates can differ by a factor of two. To fix this problem, we need to take into account the reaction stoichiometry. To arrive at a number for the reaction rate that does not depend on which component we measured, we must divide the rate of disappearance of HI by 2 (its coefficient in the balanced chemical equation):

$$\text{Rate} = -\frac{1}{2} \frac{\Delta[\text{HI}]}{\Delta t} = \frac{\Delta[\text{H}_2]}{\Delta t} = \frac{\Delta[\text{I}_2]}{\Delta t}$$

In general, for the reaction

the rate is given by

$$\text{Rate} = -\frac{1}{a} \frac{\Delta[\text{A}]}{\Delta t} = -\frac{1}{b} \frac{\Delta[\text{B}]}{\Delta t} = \frac{1}{c} \frac{\Delta[\text{C}]}{\Delta t} = \frac{1}{d} \frac{\Delta[\text{D}]}{\Delta t} \quad [14.4]$$

When we speak of the rate of a reaction without specifying a particular reactant or product, we mean the rate in this sense.*

SAMPLE EXERCISE 14.3 Relating Rates at Which Products Appear and Reactants Disappear

- (a) How is the rate at which ozone disappears related to the rate at which oxygen appears in the reaction $2 \text{O}_3(\text{g}) \longrightarrow 3 \text{O}_2(\text{g})$?
 (b) If the rate at which O_2 appears, $\Delta[\text{O}_2]/\Delta t$, is $6.0 \times 10^{-5} \text{ M/s}$ at a particular instant, at what rate is O_3 disappearing at this same time, $-\Delta[\text{O}_3]/\Delta t$?

SOLUTION

Analyze We are given a balanced chemical equation and asked to relate the rate of appearance of the product to the rate of disappearance of the reactant.

Plan We can use the coefficients in the chemical equation as shown in Equation 14.4 to express the relative rates of reactions.

Solve

(a) Using the coefficients in the balanced equation and the relationship given by Equation 14.4, we have:

$$\text{Rate} = -\frac{1}{2} \frac{\Delta[\text{O}_3]}{\Delta t} = \frac{1}{3} \frac{\Delta[\text{O}_2]}{\Delta t}$$

(b) Solving the equation from part (a) for the rate at which O_3 disappears, $-\Delta[\text{O}_3]/\Delta t$, we have:

$$-\frac{\Delta[\text{O}_3]}{\Delta t} = \frac{2}{3} \frac{\Delta[\text{O}_2]}{\Delta t} = \frac{2}{3} (6.0 \times 10^{-5} \text{ M/s}) = 4.0 \times 10^{-5} \text{ M/s}$$

Check We can apply a stoichiometric factor to convert the O_2 formation rate to the O_3 disappearance rate:

$$-\frac{\Delta[\text{O}_3]}{\Delta t} = \left(6.0 \times 10^{-5} \frac{\text{mol O}_2/\text{L}}{\text{s}}\right) \left(\frac{2 \text{ mol O}_3}{3 \text{ mol O}_2}\right) = 4.0 \times 10^{-5} \frac{\text{mol O}_3/\text{L}}{\text{s}} = 4.0 \times 10^{-5} \text{ M/s}$$

PRACTICE EXERCISE

If the rate of decomposition of N_2O_5 in the reaction $2 \text{N}_2\text{O}_5(\text{g}) \longrightarrow 4 \text{NO}_2(\text{g}) + \text{O}_2(\text{g})$ at a particular instant is $4.2 \times 10^{-7} \text{ M/s}$, what is the rate of appearance of (a) NO_2 and (b) O_2 at that instant?

Answers: (a) $8.4 \times 10^{-7} \text{ M/s}$, (b) $2.1 \times 10^{-7} \text{ M/s}$

14.3 CONCENTRATION AND RATE LAWS

One way of studying the effect of concentration on reaction rate is to determine the way in which the initial rate of a reaction depends on the initial concentrations. For example, we might study the rate of the reaction

by measuring the concentration of NH_4^+ or NO_2^- as a function of time or by measuring the volume of N_2 collected as a function of time. Because the stoichiometric coefficients on NH_4^+ , NO_2^- , and N_2 are the same, all of these rates are the same.

▼ **TABLE 14.2** shows that changing the initial concentration of either reactant changes the initial reaction rate. If we double $[\text{NH}_4^+]$ while holding $[\text{NO}_2^-]$ constant,

TABLE 14.2 • Rate Data for the Reaction of Ammonium and Nitrite Ions in Water at 25 °C

Experiment Number	Initial NH_4^+ Concentration (M)	Initial NO_2^- Concentration (M)	Observed Initial Rate (M/s)
1	0.0100	0.200	5.4×10^{-7}
2	0.0200	0.200	10.8×10^{-7}
3	0.0400	0.200	21.5×10^{-7}
4	0.200	0.0202	10.8×10^{-7}
5	0.200	0.0404	21.6×10^{-7}
6	0.200	0.0808	43.3×10^{-7}

*Equation 14.4 does not hold true if substances other than C and D are formed in significant amounts. For example, sometimes intermediate substances build in concentration before forming the final products. In that case, the relationship between the rate of disappearance of reactants and the rate of appearance of products is not given by Equation 14.4. All reactions whose rates we consider in this chapter obey Equation 14.4.

the rate doubles (compare experiments 1 and 2). If we increase $[\text{NH}_4^+]$ by a factor of 4 but leave $[\text{NO}_2^-]$ unchanged (experiments 1 and 3), the rate changes by a factor of 4, and so forth. These results indicate that the initial reaction rate is proportional to $[\text{NH}_4^+]$. When $[\text{NO}_2^-]$ is similarly varied while $[\text{NH}_4^+]$ is held constant, the rate is affected in the same manner. Thus, the rate is also directly proportional to the concentration of NO_2^- .

A CLOSER LOOK

USING SPECTROSCOPIC METHODS TO MEASURE REACTION RATES

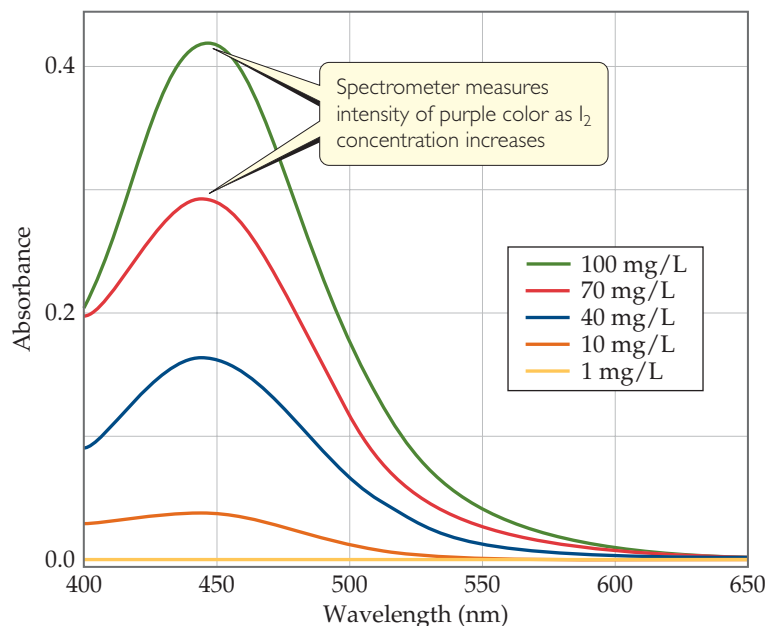

A variety of techniques can be used to monitor reactant and product concentration during a reaction, including spectroscopic methods, which rely on the ability of substances to absorb (or emit) light. Spectroscopic kinetic studies are often performed with the reaction mixture in the sample compartment of a *spectrometer*, an instrument that measures the amount of light transmitted or absorbed by a sample at different wavelengths. For kinetic studies, the spectrometer is set to measure the light absorbed at a wavelength characteristic of one of the reactants or products. In the decomposition of $\text{HI}(\text{g})$ into $\text{H}_2(\text{g})$ and $\text{I}_2(\text{g})$, for example, both HI and H_2 are colorless, whereas I_2 is violet. During the reaction, the violet color of the reaction mixture gets deeper as I_2 forms. Thus, visible light of appropriate wavelength can be used to monitor the reaction (► FIGURE 14.5).

▼ FIGURE 14.6 shows the components of a spectrometer. The spectrometer measures the amount of light absorbed by the sample by comparing the intensity of the light emitted from the light source with the intensity of the light transmitted through the sample, for various wavelengths. As the concentration of I_2 increases and its color becomes more intense, the amount of light absorbed by the reaction mixture increases, as Figure 14.5 shows, causing less light to reach the detector.

Beer's law relates the amount of light absorbed to the concentration of the absorbing substance:

$$A = \epsilon bc \quad [14.5]$$

In this equation, A is the measured absorbance, ϵ is the extinction coefficient (a characteristic of the substance being monitored at a given wavelength of light), b is the path length through which the

▲ FIGURE 14.5 Visible spectra of I_2 at different concentrations.

light passes, and c is the molar concentration of the absorbing substance. Thus, the concentration is directly proportional to absorbance. Many chemical and pharmaceutical companies routinely use Beer's law to calculate the concentration of purified solutions of the compounds that they make.

RELATED EXERCISES: 14.107, 14.108

▲ FIGURE 14.6 Components of a spectrometer.

We express the way in which the rate depends on the reactant concentrations by the equation

$$\text{Rate} = k[\text{NH}_4^+][\text{NO}_2^-] \quad [14.6]$$

An equation such as Equation 14.6, which shows how the rate depends on reactant concentrations, is called a **rate law**. For the general reaction

the rate law generally has the form

$$\text{Rate} = k[\text{A}]^m[\text{B}]^n \quad [14.7]$$

The constant k is called the **rate constant**. The magnitude of k changes with temperature and therefore determines how temperature affects rate, as we will see in Section 14.5. The exponents m and n are typically small whole numbers. As we will learn shortly, if we know m and n for a reaction, we can gain great insight into the individual steps that occur during the reaction.

GIVE IT SOME THOUGHT

How do reaction rate, rate constant, and rate law differ?

Once we know the rate law for a reaction and the reaction rate for a set of reactant concentrations, we can calculate the value of k . For example, using the values for experiment 1 in Table 14.2, we can substitute into Equation 14.6:

$$5.4 \times 10^{-7} \text{ M/s} = k(0.0100 \text{ M})(0.200 \text{ M})$$

$$k = \frac{5.4 \times 10^{-7} \text{ M/s}}{(0.0100 \text{ M})(0.200 \text{ M})} = 2.7 \times 10^{-4} \text{ M}^{-1} \text{ s}^{-1}$$

You may wish to verify that this same value of k is obtained using any of the other experimental results in Table 14.2.

Once we have both the rate law and the k value for a reaction, we can calculate the reaction rate for any set of concentrations. For example, using Equation 14.7 with $k = 2.7 \times 10^{-4} \text{ M}^{-1} \text{ s}^{-1}$, $m = 1$, and $n = 1$, we can calculate the rate for $[\text{NH}_4^+] = 0.100 \text{ M}$ and $[\text{NO}_2^-] = 0.100 \text{ M}$:

$$\text{Rate} = (2.7 \times 10^{-4} \text{ M}^{-1} \text{ s}^{-1})(0.100 \text{ M})(0.100 \text{ M}) = 2.7 \times 10^{-6} \text{ M/s}$$

GIVE IT SOME THOUGHT

Does the rate constant have the same units as the rate? Explain your answer.

Reaction Orders: The Exponents in the Rate Law

The rate law for most reactions has the form

$$\text{Rate} = k[\text{reactant 1}]^m[\text{reactant 2}]^n \dots \quad [14.8]$$

The exponents m and n are called **reaction orders**. For example, consider again the rate law for the reaction of NH_4^+ with NO_2^- :

$$\text{Rate} = k[\text{NH}_4^+][\text{NO}_2^-]$$

Because the exponent of $[\text{NH}_4^+]$ is 1, the rate is *first order* in NH_4^+ . The rate is also first order in NO_2^- . (The exponent 1 is not shown in rate laws.) The **overall reaction order** is the sum of the orders with respect to each reactant represented in the rate law. Thus, for the $\text{NH}_4^+ - \text{NO}_2^-$ reaction, the rate law has an overall reaction order of $1 + 1 = 2$, and the reaction is *second order overall*.

The exponents in a rate law indicate how the rate is affected by each reactant concentration. Because the rate at which NH_4^+ reacts with NO_2^- depends on $[\text{NH}_4^+]$ raised to the first power, the rate doubles when $[\text{NH}_4^+]$ doubles, triples when $[\text{NH}_4^+]$ triples, and so forth. Doubling or tripling $[\text{NO}_2^-]$ likewise doubles or triples the rate. If a rate

law is second order with respect to a reactant, $[A]^2$, then doubling the concentration of that substance causes the reaction rate to quadruple because $[2]^2 = 4$, whereas tripling the concentration causes the rate to increase ninefold: $[3]^2 = 9$.

The following are some additional examples of experimentally determined rate laws:

Although the exponents in a rate law are sometimes the same as the coefficients in the balanced equation, this is not necessarily the case, as Equations 14.9 and 14.10 show. For any reaction, *the rate law must be determined experimentally*. In most rate laws, reaction orders are 0, 1, or 2. However, we also occasionally encounter rate laws in which the reaction order is fractional (such as Equation 14.10) or even negative.

GIVE IT SOME THOUGHT

The experimentally determined rate law for the reaction $2 \text{NO}(\text{g}) + 2 \text{H}_2(\text{g}) \longrightarrow \text{N}_2(\text{g}) + 2 \text{H}_2\text{O}(\text{g})$ is $\text{rate} = k[\text{NO}]^2[\text{H}_2]$.

- What are the reaction orders in this rate law?
- Does doubling the concentration of NO have the same effect on rate as doubling the concentration of H_2 ?

SAMPLE EXERCISE 14.4 Relating a Rate Law to the Effect of Concentration on Rate

Consider a reaction $\text{A} + \text{B} \longrightarrow \text{C}$ for which $\text{rate} = k[\text{A}][\text{B}]^2$. Each of the following boxes represents a reaction mixture in which A is shown as red spheres and B as purple ones. Rank these mixtures in order of increasing rate of reaction.

SOLUTION

Analyze We are given three boxes containing different numbers of spheres representing mixtures containing different reactant concentrations. We are asked to use the given rate law and the compositions of the boxes to rank the mixtures in order of increasing reaction rates.

Plan Because all three boxes have the same volume, we can put the number of spheres of each kind into the rate law and calculate the rate for each box.

Solve

Box 1 contains 5 red spheres and 5 purple spheres, giving the following rate:

$$\text{Box 1: Rate} = k(5)(5)^2 = 125k$$

Box 2 contains 7 red spheres and 3 purple spheres:

$$\text{Box 2: Rate} = k(7)(3)^2 = 63k$$

Box 3 contains 3 red spheres and 7 purple spheres:

$$\text{Box 3: Rate} = k(3)(7)^2 = 147k$$

The slowest rate is $63k$ (box 2), and the highest is $147k$ (box 3). Thus, the rates vary in the order $2 < 1 < 3$.

Check Each box contains 10 spheres. The rate law indicates that in this case [B] has a greater influence on rate than [A] because B has a higher reaction order. Hence, the mixture with the highest concentration of B (most purple spheres) should react fastest. This analysis confirms the order $2 < 1 < 3$.

PRACTICE EXERCISE

Assuming that rate = $k[A][B]$, rank the mixtures represented in this Sample Exercise in order of increasing rate.

Answer: $2 = 3 < 1$

Magnitudes and Units of Rate Constants

If chemists want to compare reactions to evaluate which ones are relatively fast and which ones are relatively slow, the quantity of interest is the rate constant. A good general rule is that a large value of k ($\sim 10^9$ or higher) means a fast reaction and a small value of k (10 or lower) means a slow reaction.

GIVE IT SOME THOUGHT

What does it mean if k is 0?

The units of the rate constant depend on the overall reaction order of the rate law. In a reaction that is second order overall, for example, the units of the rate constant must satisfy the equation:

$$\text{Units of rate} = (\text{units of rate constant})(\text{units of concentration})^2$$

Hence, in our usual units of molarity for concentration and seconds for time, we have

$$\text{Units of rate constant} = \frac{\text{units of rate}}{(\text{units of concentration})^2} = \frac{M/s}{M^2} = M^{-1} s^{-1}$$

SAMPLE EXERCISE 14.5 Determining Reaction Orders and Units for Rate Constants

(a) What are the overall reaction orders for the reactions described in Equations 14.9 and 14.10? (b) What are the units of the rate constant for the rate law in Equation 14.9?

SOLUTION

Analyze We are given two rate laws and asked to express (a) the overall reaction order for each and (b) the units for the rate constant for the first reaction.

Plan The overall reaction order is the sum of the exponents in the rate law. The units for the rate constant, k , are found by using the normal units for rate (M/s) and concentration (M) in the rate law and applying algebra to solve for k .

Solve

(a) The rate of the reaction in Equation 14.9 is first order in N_2O_5 and first order overall. The reaction in Equation 14.10 is first order in $CHCl_3$ and one-half order in Cl_2 . The overall reaction order is three halves.

(b) For the rate law for Equation 14.9, we have

$$\text{Units of rate} = (\text{units of rate constant})(\text{units of concentration})$$

so

$$\text{Units of rate constant} = \frac{\text{units of rate}}{\text{units of concentration}} = \frac{M/s}{M} = s^{-1}$$

Notice that the units of the rate constant change as the overall order of the reaction changes.

PRACTICE EXERCISE

(a) What is the reaction order of the reactant H_2 in Equation 14.11? (b) What are the units of the rate constant for Equation 14.11?

Answers: (a) 1, (b) $M^{-1} s^{-1}$

Using Initial Rates to Determine Rate Laws

We have seen that the rate law for most reactions has the general form

$$\text{Rate} = k[\text{reactant 1}]^m[\text{reactant 2}]^n \dots$$

Thus, the task of determining the rate law becomes one of determining the reaction orders, m and n . In most reactions the reaction orders are 0, 1, or 2. If a reaction is zero order in a particular reactant, changing the concentration of that reactant has no effect on rate (as long as some of the reactant is present) because any concentration raised to the zero power equals 1. On the other hand, when a reaction is first order in a reactant, changes in the concentration of that reactant produce proportional changes in the rate. Thus, doubling the concentration will double the rate, and so forth. Finally, when the rate law is second order in a particular reactant, doubling its concentration increases the rate by a factor of $2^2 = 4$, tripling its concentration causes the rate to increase by a factor of $3^2 = 9$, and so forth.

In working with rate laws, it is important to realize that the *rate* of a reaction depends on concentration but the *rate constant* does not. As we will see later in this chapter, the rate constant (and hence the reaction rate) are affected by temperature and by the presence of a catalyst.

SAMPLE EXERCISE 14.6 Determining a Rate Law from Initial Rate Data

The initial rate of a reaction $A + B \longrightarrow C$ was measured for several different starting concentrations of A and B, and the results are as follows:

Experiment Number	[A] (M)	[B] (M)	Initial Rate (M/s)
1	0.100	0.100	4.0×10^{-5}
2	0.100	0.200	4.0×10^{-5}
3	0.200	0.100	16.0×10^{-5}

Using these data, determine (a) the rate law for the reaction, (b) the rate constant, (c) the rate of the reaction when $[A] = 0.050 M$ and $[B] = 0.100 M$.

SOLUTION

Analyze We are given a table of data that relates concentrations of reactants with initial rates of reaction and asked to determine (a) the rate law, (b) the rate constant, and (c) the rate of reaction for a set of concentrations not listed in the table.

Plan

(a) We assume that the rate law has the following form: $\text{Rate} = k[A]^m[B]^n$. So we must use the given data to deduce the reaction orders m and n by determining how changes in the concentration

change the rate. (b) Once we know m and n , we can use the rate law and one of the sets of data to determine the rate constant k . (c) Now that we know both the rate constant and the reaction orders, we can use the rate law with the given concentrations to calculate rate.

Solve

(a) If we compare experiments 1 and 2, we see that $[A]$ is held constant and $[B]$ is doubled. Thus, this pair of experiments shows how $[B]$ affects the rate, allowing us to deduce the order of the rate law

with respect to B. Because the rate remains the same when $[B]$ is doubled, the concentration of B has no effect on the reaction rate. The rate law is therefore zero order in B (that is, $n = 0$).

In experiments 1 and 3, $[B]$ is held constant, so these data show how $[A]$ affects rate. Holding $[B]$ constant while doubling $[A]$ increases the rate fourfold. This result indicates that rate is proportional to $[A]^2$ (that is, the reaction is second order in A). Hence, the rate law is

$$\text{Rate} = k[A]^2[B]^0 = k[A]^2$$

(b) Using the rate law and the data from experiment 1, we have

$$k = \frac{\text{rate}}{[A]^2} = \frac{4.0 \times 10^{-5} M/s}{(0.100 M)^2} = 4.0 \times 10^{-3} M^{-1} s^{-1}$$

(c) Using the rate law from part (a) and the rate constant from part (b), we have

$$\text{Rate} = k[A]^2 = (4.0 \times 10^{-3} M^{-1} s^{-1})(0.050 M)^2 = 1.0 \times 10^{-5} M/s$$

Because $[B]$ is not part of the rate law, it is irrelevant to the rate if there is at least some B present to react with A.

Check A good way to check our rate law is to use the concentrations in experiment 2 or 3 and see if we can correctly calculate the rate. Using data from experiment 3, we have

$$\text{Rate} = k[A]^2 = (4.0 \times 10^{-3} \text{ M}^{-1} \text{ s}^{-1})(0.200 \text{ M})^2 = 1.6 \times 10^{-4} \text{ M/s}$$

Thus, the rate law correctly reproduces the data, giving both the correct number and the correct units for the rate.

PRACTICE EXERCISE

The following data were measured for the reaction of nitric oxide with hydrogen:

Experiment Number	[NO] (M)	[H ₂] (M)	Initial Rate (M/s)
1	0.10	0.10	1.23×10^{-3}
2	0.10	0.20	2.46×10^{-3}
3	0.20	0.10	4.92×10^{-3}

(a) Determine the rate law for this reaction. (b) Calculate the rate constant. (c) Calculate the rate when [NO] = 0.050 M and [H₂] = 0.150 M.

Answers: (a) rate = $k[\text{NO}]^2[\text{H}_2]$, (b) $k = 1.2 \text{ M}^{-2} \text{ s}^{-1}$ (c) rate = $4.5 \times 10^{-4} \text{ M/s}$

14.4 THE CHANGE OF CONCENTRATION WITH TIME

The rate laws we have examined so far enable us to calculate the rate of a reaction from the rate constant and reactant concentrations. These rate laws can also be converted into equations that show the relationship between concentrations of reactants or products and time. The mathematics required to accomplish this conversion involves calculus. We do not expect you to be able to perform the calculus operations, but you should be able to use the resulting equations. We will apply this conversion to three of the simplest rate laws: those that are first order overall, those that are second order overall, and those that are zero order overall.

First-Order Reactions

A **first-order reaction** is one whose rate depends on the concentration of a single reactant raised to the first power. For a reaction of the type $A \rightarrow \text{products}$, the rate law may be first order:

$$\text{Rate} = -\frac{\Delta[A]}{\Delta t} = k[A]$$

This form of a rate law, which expresses how rate depends on concentration, is called the *differential rate law*. Using an operation from calculus called integration, this relationship can be transformed into an equation that relates the initial concentration of A, [A]₀, to its concentration at any other time *t*, [A]_{*t*}:

$$\ln[A]_t - \ln[A]_0 = -kt \quad \text{or} \quad \ln \frac{[A]_t}{[A]_0} = -kt \quad [14.12]$$

This form of the rate law is called the *integrated rate law*. The function “ln” in Equation 14.12 is the natural logarithm (Appendix A.2). Equation 14.12 can also be rearranged to

$$\ln[A]_t = -kt + \ln[A]_0 \quad [14.13]$$

Equations 14.12 and 14.13 can be used with any concentration units as long as the units are the same for both $[A]_t$ and $[A]_0$.

For a first-order reaction, Equation 14.12 or 14.13 can be used in several ways. Given any three of the following quantities, we can solve for the fourth: k , t , $[A]_0$, and $[A]_t$. Thus, you can use these equations to determine (1) the concentration of a reactant remaining at any time after the reaction has started, (2) the time interval required for a given fraction of a sample to react, or (3) the time interval required for a reactant concentration to fall to a certain level.

SAMPLE EXERCISE 14.7 Using the Integrated First-Order Rate Law

The decomposition of a certain insecticide in water at 12 °C follows first-order kinetics with a rate constant of 1.45 yr^{-1} . A quantity of this insecticide is washed into a lake on June 1, leading to a concentration of $5.0 \times 10^{-7} \text{ g/cm}^3$. Assume that the average temperature of the

lake is 12 °C. (a) What is the concentration of the insecticide on June 1 of the following year? (b) How long will it take for the insecticide concentration to decrease to $3.0 \times 10^{-7} \text{ g/cm}^3$?

SOLUTION

Analyze We are given the rate constant for a reaction that obeys first-order kinetics, as well as information about concentrations and times, and asked to calculate how much reactant (insecticide) remains after one year. We must also determine the time interval needed to reach a particular insecticide concentration. Because the exercise gives time in (a) and asks for time in (b), we know that the integrated rate law, Equation 14.13, is required.

Plan

(a) We are given $k = 1.45 \text{ yr}^{-1}$, $t = 1.00 \text{ yr}$ and $[\text{insecticide}]_0 = 5.0 \times 10^{-7} \text{ g/cm}^3$, and so Equation 14.13 can be solved for $[\text{insecticide}]_t$. (b) We have $k = 1.45 \text{ yr}^{-1}$, $[\text{insecticide}]_0 = 5.0 \times 10^{-7} \text{ g/cm}^3$, and $[\text{insecticide}]_t = 3.0 \times 10^{-7} \text{ g/cm}^3$, and so we can solve Equation 14.13 for time, t .

Solve

(a) Substituting the known quantities into Equation 14.13, we have

$$\ln[\text{insecticide}]_{t=1 \text{ yr}} = -(1.45 \text{ yr}^{-1})(1.00 \text{ yr}) + \ln(5.0 \times 10^{-7})$$

We use the ln function on a calculator to evaluate the second term on the right, giving

$$\ln[\text{insecticide}]_{t=1 \text{ yr}} = -1.45 + (-14.51) = -15.96$$

To obtain $[\text{insecticide}]_{t=1 \text{ yr}}$, we use the inverse natural logarithm, or e^x , function on the calculator:

$$[\text{insecticide}]_{t=1 \text{ yr}} = e^{-15.96} = 1.2 \times 10^{-7} \text{ g/cm}^3$$

Note that the concentration units for $[A]_t$ and $[A]_0$ must be the same.

(b) Again substituting into Equation 14.13, with $[\text{insecticide}]_t = 3.0 \times 10^{-7} \text{ g/cm}^3$, gives

$$\ln(3.0 \times 10^{-7}) = -(1.45 \text{ yr}^{-1})(t) + \ln(5.0 \times 10^{-7})$$

Solving for t gives

$$\begin{aligned} t &= -[\ln(3.0 \times 10^{-7}) - \ln(5.0 \times 10^{-7})]/1.45 \text{ yr}^{-1} \\ &= -(-15.02 + 14.51)/1.45 \text{ yr}^{-1} = 0.35 \text{ yr} \end{aligned}$$

Check In part (a) the concentration remaining after 1.00 yr (that is, $1.2 \times 10^{-7} \text{ g/cm}^3$) is less than the original concentration ($5.0 \times 10^{-7} \text{ g/cm}^3$), as it should be. In (b) the given concentration

($3.0 \times 10^{-7} \text{ g/cm}^3$) is greater than that remaining after 1.00 yr, indicating that the time must be less than a year. Thus, $t = 0.35 \text{ yr}$ is a reasonable answer.

PRACTICE EXERCISE

The decomposition of dimethyl ether, $(\text{CH}_3)_2\text{O}$, at 510 °C is a first-order process with a rate constant of $6.8 \times 10^{-4} \text{ s}^{-1}$:

If the initial pressure of $(\text{CH}_3)_2\text{O}$ is 135 torr, what is its pressure after 1420 s?

Answer: 51 torr

Equation 14.13 can be used to verify whether a reaction is first order and to determine its rate constant. This equation has the form of the general equation for a straight line, $y = mx + b$, in which m is the slope and b is the y -intercept of the line (Appendix A.4):

$$\begin{array}{ccccccc} \ln [A]_t & = & -kt & + & \ln [A]_0 \\ \updownarrow & & \updownarrow & & \updownarrow \\ y & = & mx & + & b \end{array}$$

For a first-order reaction, therefore, a graph of $\ln[A]_t$ versus time gives a straight line with a slope of $-k$ and a y -intercept of $\ln[A]_0$. A reaction that is not first order will not yield a straight line.

As an example, consider the conversion of methyl isonitrile (CH_3NC) to its isomer acetonitrile (CH_3CN) (► FIGURE 14.7). Because experiments show that the reaction is first order, we can write the rate equation:

$$\ln[\text{CH}_3\text{NC}]_t = -kt + \ln[\text{CH}_3\text{NC}]_0$$

We run the reaction at a temperature at which methyl isonitrile is a gas (199°C), and ▼ FIGURE 14.8(a) shows how the pressure of this gas varies with time. We can use pressure as a unit of concentration for a gas because we know from the ideal-gas law the pressure is directly proportional to the number of moles per unit volume. Figure 14.8(b) shows that a plot of the natural logarithm of the pressure versus time is a straight line. The slope of this line is $-5.1 \times 10^{-5} \text{ s}^{-1}$. (You should verify this for yourself, remembering that your result may vary slightly from ours because of inaccuracies associated with reading the graph.) Because the slope of the line equals $-k$, the rate constant for this reaction equals $5.1 \times 10^{-5} \text{ s}^{-1}$.

▲ FIGURE 14.7 The first-order reaction of CH_3NC conversion into CH_3CN .

Second-Order Reactions

A **second-order reaction** is one whose rate depends either on a reactant concentration raised to the second power or on the concentrations of two reactants each raised to the first power. For simplicity, let's consider reactions of the type $\text{A} \longrightarrow \text{products}$ or $\text{A} + \text{B} \longrightarrow \text{products}$ that are second order in just one reactant, A:

$$\text{Rate} = -\frac{\Delta[\text{A}]}{\Delta t} = k[\text{A}]^2$$

With the use of calculus, this differential rate law can be used to derive the integrated rate law

$$\frac{1}{[\text{A}]_t} = kt + \frac{1}{[\text{A}]_0} \quad [14.14]$$

This equation, like Equation 14.13, has four variables, k , t , $[\text{A}]_0$, and $[\text{A}]_t$, and any one of these can be calculated knowing the other three. Equation 14.14 also has the form of a straight line ($y = mx + b$). If the reaction is second order, a plot of $1/[\text{A}]_t$ versus t yields a straight line with slope k and y -intercept $1/[\text{A}]_0$. One way to distinguish between first- and second-order rate laws is to graph both $\ln[\text{A}]_t$ and $1/[\text{A}]_t$ against t . If the $\ln[\text{A}]_t$ plot is linear, the reaction is first order; if the $1/[\text{A}]_t$ plot is linear, the reaction is second order.

GO FIGURE

What can you conclude from the fact that the plot of $\ln P$ versus t is linear?

◀ FIGURE 14.8 Kinetic data for conversion of methyl isonitrile into acetonitrile.

SAMPLE EXERCISE 14.8 Determining Reaction Order from the Integrated Rate Law

The following data were obtained for the gas-phase decomposition of nitrogen dioxide at 300 °C, $\text{NO}_2(\text{g}) \longrightarrow \text{NO}(\text{g}) + \frac{1}{2} \text{O}_2(\text{g})$:

Time (s)	$[\text{NO}_2]$ (M)
0.0	0.01000
50.0	0.00787
100.0	0.00649
200.0	0.00481
300.0	0.00380

Is the reaction first or second order in NO_2 ?

SOLUTION

Analyze We are given the concentrations of a reactant at various times during a reaction and asked to determine whether the reaction is first or second order.

Plan We can plot $\ln[\text{NO}_2]$ and $1/[\text{NO}_2]$ against time. One or the other will be linear, indicating whether the reaction is first or second order.

Solve To graph $\ln[\text{NO}_2]$ and $1/[\text{NO}_2]$ against time, we will first prepare the following table from the data given:

Time (s)	$[\text{NO}_2]$ (M)	$\ln[\text{NO}_2]$	$1/[\text{NO}_2]$
0.0	0.01000	-4.605	100
50.0	0.00787	-4.845	127
100.0	0.00649	-5.037	154
200.0	0.00481	-5.337	208
300.0	0.00380	-5.573	263

As **FIGURE 14.9** shows, only the plot of $1/[\text{NO}_2]$ versus time is linear. Thus, the reaction obeys a second-order rate law: $\text{Rate} = k[\text{NO}_2]^2$. From the slope of this straight-line graph, we determine that $k = 0.543 \text{ M}^{-1} \text{ s}^{-1}$ for the disappearance of NO_2 .

PRACTICE EXERCISE

The decomposition of NO_2 discussed in the Sample Exercise is second order in NO_2 with $k = 0.543 \text{ M}^{-1} \text{ s}^{-1}$. If the initial concentration of NO_2 in a closed vessel is 0.0500, what is the concentration of this reactant after 0.500 hr?

Answer: $[\text{NO}_2] = 1.00 \times 10^{-3} \text{ M}$

▲ FIGURE 14.9 Kinetic data for decomposition of NO_2 .

Zero-Order Reactions

We've seen that in a first-order reaction the concentration of a reactant A decreases non-linearly, as shown by the red curve in ► **FIGURE 14.10**. As [A] declines, the *rate* at which it disappears declines in proportion. A **zero-order reaction** is one in which the rate of disappearance of A is *independent* of [A]. The rate law for a zero-order reaction is

$$\text{Rate} = \frac{-\Delta[A]}{\Delta t} = k$$

The integrated rate law for a zero-order reaction is

$$[A]_t = -kt + [A]_0$$

where $[A]_t$ is the concentration of A at time t and $[A]_0$ is the initial concentration. This is the equation for a straight line with vertical intercept $[A]_0$ and slope $-kt$, as shown in the blue curve in Figure 14.10.

The most common type of zero-order reaction occurs when a gas undergoes decomposition on the surface of a solid. If the surface is completely covered by decomposing molecules, the rate of reaction is constant because the number of reacting surface molecules is constant, so long as there is some gas-phase substance left.

Half-Life

The **half-life** of a reaction, $t_{1/2}$, is the time required for the concentration of a reactant to reach half its initial value, $[A]_{t_{1/2}} = \frac{1}{2}[A]_0$. Half-life is a convenient way to describe how fast a reaction occurs, especially if it is a first-order process. A fast reaction has a short half-life.

We can determine the half-life of a first-order reaction by substituting $[A]_{t_{1/2}} = \frac{1}{2}[A]_0$ for $[A]_t$ and $t_{1/2}$ for t in Equation 14.12:

$$\begin{aligned} \ln \frac{\frac{1}{2}[A]_0}{[A]_0} &= -kt_{1/2} \\ \ln \frac{1}{2} &= -kt_{1/2} \\ t_{1/2} &= -\frac{\ln \frac{1}{2}}{k} = \frac{0.693}{k} \end{aligned}$$

[14.15]

From Equation 14.15, we see that $t_{1/2}$ for a first-order rate law does not depend on the initial concentration of any reactant. Consequently, the half-life remains constant throughout the reaction. If, for example, the concentration of a reactant is 0.120 M at some instant in the reaction, it will be $\frac{1}{2}(0.120 \text{ M}) = 0.060 \text{ M}$ after one half-life. After one more half-life passes, the concentration will drop to 0.030 M, and so on. Equation 14.15 also indicates that, for a first-order reaction, we can calculate $t_{1/2}$ if we know k and calculate k if we know $t_{1/2}$.

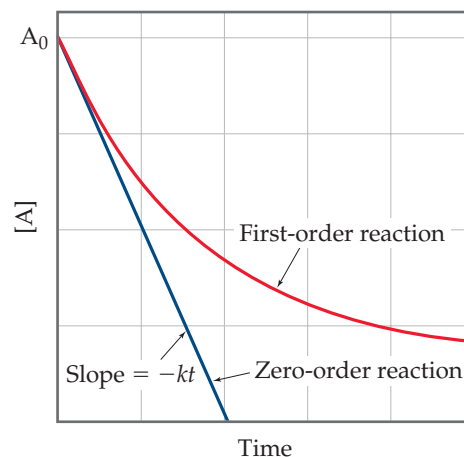

The change in concentration over time for the first-order rearrangement of gaseous methyl isonitrile at 199 °C is graphed in ► **FIGURE 14.11**. Because the concentration of this gas is directly proportional to its pressure during the reaction, we have chosen to plot pressure rather than concentration in this graph. The first half-life occurs at 13,600 s (3.78 hr). At a time 13,600 s later, the methyl isonitrile pressure (and therefore, concentration) has decreased to half of one-half, or one-fourth, of the initial value. *In a first-order reaction, the concentration of the reactant decreases by one-half in each of a series of regularly spaced time intervals, each interval equal to $t_{1/2}$.*

GIVE IT SOME THOUGHT

If a solution containing 10.0 g of a substance reacts by first-order kinetics, how many grams remain after 3 half-lives?

GO FIGURE

At which times during the reaction would you have trouble distinguishing a zero-order reaction from a first-order reaction?

▲ **FIGURE 14.10** Comparison of first-order and zero-order reactions for the disappearance of reactant A with time.

CHEMISTRY PUT TO WORK

Methyl Bromide in the Atmosphere

The compounds known as chlorofluorocarbons (CFCs) are well-known agents responsible for the destruction of Earth's protective ozone layer. Another simple molecule that has the potential to destroy the stratospheric ozone layer is methyl bromide, CH_3Br (▼ FIGURE 14.12). Because this substance has a wide range of uses, including antifungal treatment of plant seeds, it has been produced in large quantities in the past (about 150 million pounds per year worldwide in 1997, at the height of its production). In the stratosphere, the C—Br bond is broken through absorption of short-wavelength radiation. The resultant Br atoms then catalyze decomposition of O_3 .

Methyl bromide is removed from the lower atmosphere by a variety of mechanisms, including a slow reaction with ocean water:

To determine the potential importance of CH_3Br in destruction of the ozone layer, it is important to know how rapidly the reaction in Equation 14.16 and all other reactions remove CH_3Br from the lower atmosphere before it can diffuse into the stratosphere.

The average lifetime of CH_3Br in Earth's lower atmosphere is difficult to measure because the conditions that exist in the atmosphere are too complex to be simulated in the laboratory. Instead, scientists analyzed nearly 4000 atmospheric samples collected above the Pacific Ocean for the presence of several trace organic substances, including methyl bromide. From these measurements, it was possible to estimate the *atmospheric residence time* for CH_3Br .

The atmospheric residence time is related to the half-life for CH_3Br in the lower atmosphere, assuming the CH_3Br decomposes by a first-order process. From the experimental data, the half-life for methyl bromide in the lower atmosphere is estimated to be 0.8 ± 0.1 year. That is, a collection of CH_3Br molecules present at any given time will, on average, be 50% decomposed after 0.8 year, 75% decomposed after 1.6 years, and so on. A half-life of 0.8 year, while comparatively short, is still sufficiently long so that CH_3Br contributes significantly to the destruction of the ozone layer.

In 1997 an international agreement was reached to phase out use of methyl bromide in developed countries by 2005. However, in recent years exemptions for critical agricultural use have been requested and granted. Nevertheless, worldwide production was down to 25 million pounds in 2009, two-thirds of which is used in the United States.

RELATED EXERCISE: 14.124

◀ FIGURE 14.12 Distribution and fate of methyl bromide in Earth's atmosphere.

SAMPLE EXERCISE 14.9 Determining the Half-Life of a First-Order Reaction

The reaction of $\text{C}_4\text{H}_9\text{Cl}$ with water is a first-order reaction. (a) Use Figure 14.4 to estimate the half-life for this reaction. (b) Use the half-life from (a) to calculate the rate constant.

SOLUTION

Analyze We are asked to estimate the half-life of a reaction from a graph of concentration versus time and then to use the half-life to calculate the rate constant for the reaction.

Plan

(a) To estimate a half-life, we can select a concentration and then determine the time required for the concentration to decrease to half of that value. (b) Equation 14.15 is used to calculate the rate constant from the half-life.

Solve

(a) From the graph, we see that the initial value of $[\text{C}_4\text{H}_9\text{Cl}]$ is 0.100 M . The half-life for this first-order reaction is the time required for $[\text{C}_4\text{H}_9\text{Cl}]$ to decrease to 0.050 M , which we can read off the graph. This point occurs at approximately 340 s .

(b) Solving Equation 14.15 for k , we have

$$k = \frac{0.693}{t_{1/2}} = \frac{0.693}{340\text{ s}} = 2.0 \times 10^{-3}\text{ s}^{-1}$$

Check At the end of the second half-life, which should occur at 680 s , the concentration should have decreased by yet another factor of 2, to 0.025 . Inspection of the graph shows that this is indeed the case.

PRACTICE EXERCISE

(a) Using Equation 14.15, calculate $t_{1/2}$ for the decomposition of the insecticide described in Sample Exercise 14.7. (b) How long does it take for the concentration of the insecticide to reach one-quarter of the initial value?

Answers: (a) $0.478\text{ yr} = 1.51 \times 10^7\text{ s}$, (b) it takes two half-lives, $2(0.478\text{ yr}) = 0.956\text{ yr}$

The half-life for second-order and other reactions depends on reactant concentrations and therefore changes as the reaction progresses. We obtained Equation 14.15 for the half-life for a first-order reaction by substituting $[\text{A}]_{t_{1/2}} = \frac{1}{2}[\text{A}]_0$ for $[\text{A}]_t$ and $t_{1/2}$ for t in Equation 14.12. We find the half-life of a second-order reaction by making the same substitutions into Equation 14.14:

$$\begin{aligned} \frac{1}{\frac{1}{2}[\text{A}]_0} &= kt_{1/2} + \frac{1}{[\text{A}]_0} \\ \frac{2}{[\text{A}]_0} - \frac{1}{[\text{A}]_0} &= kt_{1/2} \\ t_{1/2} &= \frac{1}{k[\text{A}]_0} \end{aligned} \quad [14.17]$$

In this case the half-life depends on the initial concentration of reactant—the lower the initial concentration, the longer the half-life.

GIVE IT SOME THOUGHT

How does the half-life of a second-order reaction change as the reaction proceeds?

14.5 TEMPERATURE AND RATE

The rates of most chemical reactions increase as the temperature rises. For example, dough rises faster at room temperature than when refrigerated, and plants grow more rapidly in warm weather than in cold. We can see the effect of temperature on reaction rate by observing a chemiluminescence reaction (one that produces light). The characteristic glow of fireflies is a familiar example of chemiluminescence. Another is the light produced by Cyalume® light sticks, which contain chemicals that produce chemiluminescence when mixed. As seen in ► **FIGURE 14.13**, these light sticks produce a brighter light at higher temperature. The amount of light produced is greater because the rate of the reaction is faster at the higher temperature. Although the light stick glows more brightly initially, its luminescence also dies out more rapidly at the higher temperature.

► **FIGURE 14.13** Temperature affects the rate of the chemiluminescence reaction in light sticks.

Hot water

Cold water

▲ **FIGURE 14.14** Temperature dependence of the rate constant for methyl isonitrile conversion to acetonitrile. The four points indicated are used in Sample Exercise 14.11.

How is this experimentally observed temperature effect reflected in the rate law? The faster rate at higher temperature is due to an increase in the rate constant with increasing temperature. For example, let's reconsider the first-order reaction $\text{CH}_3\text{NC} \longrightarrow \text{CH}_3\text{CN}$. ◀ **FIGURE 14.14** shows the rate constant for this reaction as a function of temperature. The rate constant and, hence, the rate of the reaction increase rapidly with temperature, approximately doubling for each 10 °C rise.

The Collision Model

Reaction rates are affected both by reactant concentrations and by temperature. The **collision model**, based on the kinetic-molecular theory (Section 10.7), accounts for both of these effects at the molecular level. The central idea of the collision model is that molecules must collide to react. The greater the number of collisions per second, the greater the reaction rate. As reactant concentration increases, therefore, the number of collisions increases, leading to an increase in reaction rate. According to the kinetic-molecular theory of gases, increasing the temperature increases

molecular speeds. As molecules move faster, they collide more forcefully (with more energy) and more frequently, increasing reaction rates.

For a reaction to occur, though, more is required than simply a collision. For most reactions, only a tiny fraction of collisions leads to a reaction. For example, in a mixture of H_2 and I_2 at ordinary temperatures and pressures, each molecule undergoes about 10^{10} collisions per second. If every collision between H_2 and I_2 resulted in the formation of HI , the reaction would be over in much less than a second. Instead, at room temperature the reaction proceeds very slowly because only about one in every 10^{13} collisions produces a reaction. What keeps the reaction from occurring more rapidly?

The Orientation Factor

In most reactions, molecules must be oriented in a certain way during collision for a reaction to occur. The relative orientations of the molecules during collision determine whether the atoms are suitably positioned to form new bonds. For example, consider the reaction

which takes place if the collision brings Cl atoms together to form Cl_2 , as shown at the top in **FIGURE 14.15**. In contrast, the collision shown at the bottom in this figure is ineffective and does not yield products.

▼ **FIGURE 14.15** Molecular collisions may or may not lead to a chemical reaction between Cl and NOCl.

◀ **FIGURE 14.16** Energy is needed to overcome a barrier between initial and final states.

Activation Energy

In addition to molecular orientation during collisions, another factor is usually even more important in determining whether a particular collision results in reaction. In 1888 the Swedish chemist Svante Arrhenius suggested that molecules must possess a certain minimum amount of energy to react. According to the collision model, this energy comes from the kinetic energies of the colliding molecules. Upon collision, the kinetic energy of the molecules can be used to stretch, bend, and ultimately break bonds, leading to chemical reactions. That is, the kinetic energy is used to change the potential energy of the molecule. If molecules are moving too slowly—in other words, with too little kinetic energy—they merely bounce off one another without changing. The minimum energy required to initiate a chemical reaction is called the **activation energy**, E_a , and its value varies from reaction to reaction.

The situation during reactions is analogous to that shown in ▲ **FIGURE 14.16**. The player needs to move his ball over the hill in the direction of the cup. The hill is a *barrier* between ball and cup. To reach the cup, the player must impart enough kinetic energy with the putter to move the ball to the top of the barrier. If he does not impart enough energy, the ball will roll partway up the hill and then back down toward him. In the same way, molecules require a certain minimum energy to break existing bonds during a chemical reaction. We can think of this minimum energy as an *energy barrier*. In the rearrangement of methyl isonitrile to acetonitrile, for example, we might imagine the reaction passing through an intermediate state in which the $\text{N}\equiv\text{C}$ portion of the methyl isonitrile molecule is sideways:

► **FIGURE 14.17** shows that energy must be supplied to stretch the bond between the H_3C group and the $\text{N}\equiv\text{C}$ group to allow the $\text{N}\equiv\text{C}$ group to rotate. After the $\text{N}\equiv\text{C}$ group has twisted sufficiently, the $\text{C}-\text{C}$ bond begins to form, and the energy of the molecule drops. Thus, the barrier to formation of acetonitrile represents the energy necessary to force the molecule through the relatively unstable intermediate state, analogous to forcing the ball in Figure 14.16 over the hill. The difference between the energy of the starting molecule and the highest energy along the reaction pathway is the activation energy, E_a . The molecule having the arrangement of atoms shown at the top of the barrier is called either the **activated complex** or the **transition state**.

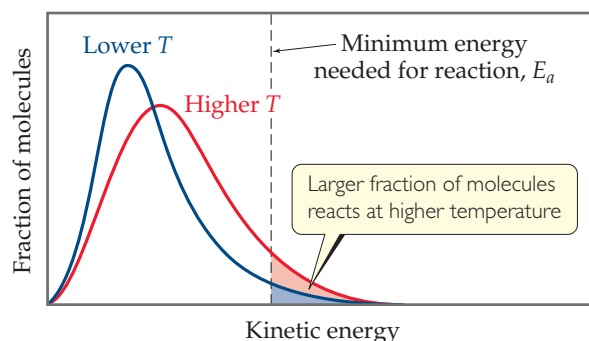

The conversion of $\text{H}_3\text{C}-\text{N}\equiv\text{C}$ to $\text{H}_3\text{C}-\text{C}\equiv\text{N}$ is exothermic. Figure 14.17 therefore shows the product as having a lower energy than the reactant. The energy change for the reaction, ΔE , has no effect on reaction rate, however. *The rate depends on the magnitude of E_a ; generally, the lower the value of E_a is, the faster the reaction.*

Notice that the reverse reaction is endothermic. The activation energy for the reverse reaction is equal to the energy that must be overcome if approaching the barrier from the right: $\Delta E + E_a$.

▲ **FIGURE 14.17** Energy profile for conversion of methyl isonitrile (H_3CNC) to its isomer acetonitrile (H_3CCN).

► **FIGURE 14.18** The effect of temperature on the distribution of kinetic energies of molecules in a sample.

Any particular methyl isonitrile molecule acquires sufficient energy to overcome the energy barrier through collisions with other molecules. Recall from the kinetic-molecular theory of gases that, at any instant, gas molecules are distributed in energy over a wide range. ∞ (Section 10.7) ▲ **FIGURE 14.18** shows the distribution of kinetic energies for two temperatures, comparing them with the minimum energy needed for reaction, E_a . At the higher temperature a much greater fraction of the molecules have kinetic energy greater than E_a , which leads to a greater rate of reaction.

▲ GIVE IT SOME THOUGHT

Suppose we have two reactions, $A \longrightarrow B$ and $B \longrightarrow C$. You can isolate B, and it is stable. Is B the transition state for the reaction $A \longrightarrow C$?

The fraction of molecules that have an energy equal to or greater than E_a is given by the expression

$$f = e^{-E_a/RT} \quad [14.18]$$

In this equation R is the gas constant (8.314 J/mol-K) and T is the absolute temperature. To get an idea of the magnitude of f , let's suppose that E_a is 100 kJ/mol, a value typical of many reactions, and that T is 300 K. The calculated value of f is 3.9×10^{-18} , an extremely small number! At 310 K, $f = 1.4 \times 10^{-17}$. Thus, a 10-degree increase in temperature produces a 3.6-fold increase in the fraction of molecules possessing at least 100 kJ/mol of energy.

▲ GIVE IT SOME THOUGHT

In a chemical reaction, why does not every collision between reactant molecules result in formation of a product molecule?

The Arrhenius Equation

Arrhenius noted that for most reactions the increase in rate with increasing temperature is nonlinear (Figure 14.14). He found that most reaction-rate data obeyed an equation based on (a) the fraction of molecules possessing energy E_a or greater, (b) the number of collisions per second, and (c) the fraction of collisions that have the appropriate orientation. These three factors are incorporated into the **Arrhenius equation**:

$$k = Ae^{-E_a/RT} \quad [14.19]$$

In this equation k is the rate constant, E_a is the activation energy, R is the gas constant (8.314 J/mol-K), and T is the absolute temperature. The **frequency factor**, A , is constant, or nearly so, as temperature is varied. This factor is related to the frequency of collisions and the probability that the collisions are favorably oriented for reaction.* As the magnitude of E_a increases, k decreases because the fraction of molecules that possess the required energy is smaller. Thus, *reaction rates decrease as E_a increases*.

*Because collision frequency increases with temperature, A also has some temperature dependence, but this dependence is much smaller than the exponential term. Therefore, A is considered approximately constant.

SAMPLE EXERCISE 14.10 Relating Energy Profiles to Activation Energies and Speeds of Reaction

Consider a series of reactions having these energy profiles:

Rank the reactions from slowest to fastest assuming that they have nearly the same value for the frequency factor A .

SOLUTION

The lower the activation energy, the faster the reaction. The value of ΔE does not affect the rate. Hence, the order from slowest reaction to fastest is $2 < 3 < 1$.

PRACTICE EXERCISE

Rank the reverse reactions from slowest to fastest.

Answer: $2 < 1 < 3$ because, if you approach the barrier from the right, the E_a values are 40 kJ/mol for reverse reaction 2, 25 kJ/mol for reverse reaction 1, and 15 kJ/mol for reverse reaction 3.

Determining the Activation Energy

We can calculate the activation energy for a reaction by manipulating the Arrhenius equation. Taking the natural log of both sides of Equation 14.19, we obtain

$$\ln k = -\frac{E_a}{RT} + \ln A \quad [14.20]$$

$$y = mx + b$$

which has the form of the equation for a straight line. A graph of $\ln k$ versus $1/T$ is a line with a slope equal to $-E_a/R$ and a y -intercept equal to $\ln A$. Thus, the activation energy can be determined by measuring k at a series of temperatures, graphing $\ln k$ versus $1/T$, and calculating E_a from the slope of the resultant line.

We can also use Equation 14.20 to evaluate E_a in a nongraphical way if we know the rate constant of a reaction at two or more temperatures. For example, suppose that at two different temperatures T_1 and T_2 a reaction has rate constants k_1 and k_2 . For each condition, we have

$$\ln k_1 = -\frac{E_a}{RT_1} + \ln A \quad \text{and} \quad \ln k_2 = -\frac{E_a}{RT_2} + \ln A$$

Subtracting $\ln k_2$ from $\ln k_1$ gives

$$\ln k_1 - \ln k_2 = \left(-\frac{E_a}{RT_1} + \ln A \right) - \left(-\frac{E_a}{RT_2} + \ln A \right)$$

Simplifying this equation and rearranging give

$$\ln \frac{k_1}{k_2} = \frac{E_a}{R} \left(\frac{1}{T_2} - \frac{1}{T_1} \right) \quad [14.21]$$

Equation 14.21 provides a convenient way to calculate a rate constant k_1 at some temperature T_1 when we know the activation energy and the rate constant k_2 at some other temperature T_2 .

SAMPLE EXERCISE 14.11 Determining the Activation Energy

The following table shows the rate constants for the rearrangement of methyl isonitrile at various temperatures (these are the data points in Figure 14.14):

Temperature (°C)	k (s ⁻¹)
189.7	2.52×10^{-5}
198.9	5.25×10^{-5}
230.3	6.30×10^{-4}
251.2	3.16×10^{-3}

(a) From these data, calculate the activation energy for the reaction. (b) What is the value of the rate constant at 430.0 K?

SOLUTION

Analyze We are given rate constants, k , measured at several temperatures and asked to determine the activation energy, E_a , and the rate constant, k , at a particular temperature.

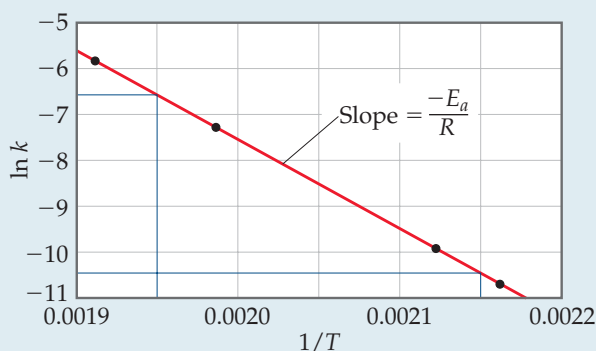

Plan We can obtain E_a from the slope of a graph of $\ln k$ versus $1/T$. Once we know E_a , we can use Equation 14.21 together with the given rate data to calculate the rate constant at 430.0 K.

Solve

(a) We must first convert the temperatures from degrees Celsius to kelvins. We then take the inverse of each temperature, $1/T$, and the natural log of each rate constant, $\ln k$. This gives us the table shown at the right:

T (K)	$1/T$ (K ⁻¹)	$\ln k$
462.9	2.160×10^{-3}	-10.589
472.1	2.118×10^{-3}	-9.855
503.5	1.986×10^{-3}	-7.370
524.4	1.907×10^{-3}	-5.757

A graph of $\ln k$ versus $1/T$ is a straight line (► **FIGURE 14.19**).

▲ **FIGURE 14.19** Graphical determination of activation energy E_a .

The slope of the line is obtained by choosing any two well-separated points and using the coordinates of each:

$$\text{Slope} = \frac{\Delta y}{\Delta x} = \frac{-6.6 - (-10.4)}{0.00195 - 0.00215} = -1.9 \times 10^4$$

$$\text{Slope} = -\frac{E_a}{R}$$

Because logarithms have no units, the numerator in this equation is dimensionless. The denominator has the units of $1/T$, namely, K⁻¹. Thus, the overall units for the slope are K. The slope equals $-E_a/R$. We use the value for the gas constant R in units of J/mol·K (Table 10.2). We thus obtain

$$\begin{aligned} E_a &= -(\text{slope})(R) = -(-1.9 \times 10^4 \text{ K}) \left(8.314 \frac{\text{J}}{\text{mol}\cdot\text{K}} \right) \left(\frac{1 \text{ kJ}}{1000 \text{ J}} \right) \\ &= 1.6 \times 10^2 \text{ kJ/mol} = 160 \text{ kJ/mol} \end{aligned}$$

We report the activation energy to only two significant figures because we are limited by the precision with which we can read the graph in Figure 14.19.

(b) To determine the rate constant, k_1 , at $T_1 = 430.0$ K, we can use Equation 14.21 with $E_a = 160$ kJ/mol and one of the rate constants and temperatures from the given data, such as $k_2 = 2.52 \times 10^{-5} \text{ s}^{-1}$ and $T_2 = 462.9$ K:

$$\ln\left(\frac{k_1}{2.52 \times 10^{-5} \text{ s}^{-1}}\right) = \left(\frac{160 \text{ kJ/mol}}{8.314 \text{ J/mol-K}}\right)\left(\frac{1}{462.9 \text{ K}} - \frac{1}{430.0 \text{ K}}\right)\left(\frac{1000 \text{ J}}{1 \text{ kJ}}\right) = -3.18$$

Thus,

$$\frac{k_1}{2.52 \times 10^{-5} \text{ s}^{-1}} = e^{-3.18} = 4.15 \times 10^{-2}$$

$$k_1 = (4.15 \times 10^{-2})(2.52 \times 10^{-5} \text{ s}^{-1}) = 1.0 \times 10^{-6} \text{ s}^{-1}$$

Note that the units of k_1 are the same as those of k_2 .

PRACTICE EXERCISE

Using the data in Sample Exercise 14.11, calculate the rate constant for the rearrangement of methyl isonitrile at 280 °C.

Answer: $2.2 \times 10^{-2} \text{ s}^{-1}$

14.6 REACTION MECHANISMS

A balanced equation for a chemical reaction indicates the substances present at the start of the reaction and those present at the end of the reaction. It provides no information, however, about the detailed steps that occur at the molecular level as the reactants are turned into products. The steps by which a reaction occurs is called the **reaction mechanism**. At the most sophisticated level, a reaction mechanism describes the order in which bonds are broken and formed and the changes in relative positions of the atoms in the course of the reaction.

Elementary Reactions

We have seen that reactions take place because of collisions between reacting molecules. For example, the collisions between molecules of methyl isonitrile (CH_3NC) can provide the energy to allow the CH_3NC to rearrange to acetonitrile:

Similarly, the reaction of NO and O_3 to form NO_2 and O_2 appears to occur as a result of a single collision involving suitably oriented and sufficiently energetic NO and O_3 molecules:

Both reactions occur in a single event or step and are called **elementary reactions**.

The number of molecules that participate as reactants in an elementary reaction defines the **molecularity** of the reaction. If a single molecule is involved, the reaction is **unimolecular**. The rearrangement of methyl isonitrile is a unimolecular process. Elementary reactions involving the collision of two reactant molecules are **bimolecular**. The reaction between NO and O_3 is bimolecular. Elementary reactions involving the simultaneous collision of three molecules are **termolecular**. Termolecular reactions are far less probable than unimolecular or bimolecular processes and are rarely encountered. The chance that four or more molecules will collide simultaneously with any regularity is even more remote; consequently, such collisions are never proposed as part of a reaction mechanism.

GIVE IT SOME THOUGHT

What is the molecularity of the elementary reaction?

Multistep Mechanisms

The net change represented by a balanced chemical equation often occurs by a *multistep mechanism* consisting of a sequence of elementary reactions. For example, below 225 °C, the reaction

appears to proceed in two elementary reactions (or two *elementary steps*), each of which is bimolecular. First, two NO_2 molecules collide, and an oxygen atom is transferred from one to the other. The resultant NO_3 then collides with a CO molecule and transfers an oxygen atom to it:

Thus, we say that the reaction occurs by a two-step mechanism.

The chemical equations for the elementary reactions in a multistep mechanism must always add to give the chemical equation of the overall process. In the present example the sum of the two elementary reactions is

Simplifying this equation by eliminating substances that appear on both sides gives Equation 14.23, the net equation for the process.

Because NO_3 is neither a reactant nor a product of the reaction—it is formed in one elementary reaction and consumed in the next—it is called an **intermediate**. Multistep mechanisms involve one or more intermediates. Intermediates are not the same as transition states, as shown in ▼ FIGURE 14.20. Intermediates can be stable and can therefore sometimes be identified and even isolated. Transition states, on the other hand, are always inherently unstable and as such can never be isolated. Nevertheless, the use of advanced “ultrafast” techniques sometimes allows us to characterize them.

► FIGURE 14.20 The energy profile of a reaction, showing transition states and an intermediate.

SAMPLE EXERCISE 14.12 Determining Molecularity and Identifying Intermediates

It has been proposed that the conversion of ozone into O_2 proceeds by a two-step mechanism:

- (a) Describe the molecularity of each elementary reaction in this mechanism.
 (b) Write the equation for the overall reaction. (c) Identify the intermediate(s).

SOLUTION

Analyze We are given a two-step mechanism and asked for (a) the molecularities of each of the two elementary reactions, (b) the equation for the overall process, and (c) the intermediate.

Plan The molecularity of each elementary reaction depends on the number of reactant molecules in the equation for that reaction. The overall equation is the sum of the equations for the elementary reactions. The intermediate is a substance formed in one step of the mechanism and used in another and therefore not part of the equation for the overall reaction.

Solve

(a) The first elementary reaction involves a single reactant and is consequently unimolecular. The second reaction, which involves two reactant molecules, is bimolecular.

(b) Adding the two elementary reactions gives

Because $\text{O}(\text{g})$ appears in equal amounts on both sides of the equation, it can be eliminated to give the net equation for the chemical process:

(c) The intermediate is $\text{O}(\text{g})$. It is neither an original reactant nor a final product but is formed in the first step of the mechanism and consumed in the second.

PRACTICE EXERCISE

For the reaction

the proposed mechanism is

(a) Is the proposed mechanism consistent with the equation for the overall reaction? (b) What is the molecularity of each step of the mechanism? (c) Identify the intermediate(s).

Answers: (a) Yes, the two equations add to yield the equation for the reaction. (b) The first elementary reaction is unimolecular, and the second one is bimolecular. (c) $\text{Mo}(\text{CO})_5$

Rate Laws for Elementary Reactions

In Section 14.3 we stressed that rate laws must be determined experimentally; they cannot be predicted from the coefficients of balanced chemical equations. We are now in a position to understand why this is so. Every reaction is made up of a series of one or more elementary steps, and the rate laws and relative speeds of these steps dictate the overall rate law for the reaction. Indeed, the rate law for a reaction can be determined from its mechanism, as we will see shortly, and compared with the experimental rate law. Thus, our next challenge in kinetics is to arrive at reaction mechanisms that lead to rate laws consistent with those observed experimentally. We start by examining the rate laws of elementary reactions.

Elementary reactions are significant in a very important way: *If a reaction is elementary, its rate law is based directly on its molecularity.* For example, consider the unimolecular reaction

As the number of A molecules increases, the number that react in a given time interval increases proportionally. Thus, the rate of a unimolecular process is first order:

$$\text{Rate} = k[\text{A}]$$

For bimolecular elementary steps, the rate law is second order, as in the reaction

The second-order rate law follows directly from collision theory. If we double the concentration of A, the number of collisions between molecules of A and B doubles; likewise, if we double [B], the number of collisions between A and B doubles. Therefore, the rate law is first order in both [A] and [B] and second order overall.

The rate laws for all feasible elementary reactions are given in ► **TABLE 14.3**. Notice how each rate law follows directly from the molecularity of the reaction. It is important to remember, however, that we cannot tell by merely looking at a balanced, overall chemical equation whether the reaction involves one or several elementary steps.

TABLE 14.3 • Elementary Reactions and Their Rate Laws

Molecularity	Elementary Reaction	Rate Law
Unimolecular	$A \longrightarrow \text{products}$	Rate = $k[A]$
Bimolecular	$A + A \longrightarrow \text{products}$	Rate = $k[A]^2$
Bimolecular	$A + B \longrightarrow \text{products}$	Rate = $k[A][B]$
Termolecular	$A + A + A \longrightarrow \text{products}$	Rate = $k[A]^3$
Termolecular	$A + A + B \longrightarrow \text{products}$	Rate = $k[A]^2[B]$
Termolecular	$A + B + C \longrightarrow \text{products}$	Rate = $k[A][B][C]$

SAMPLE EXERCISE 14.13 Predicting the Rate Law for an Elementary Reaction

If the following reaction occurs in a single elementary reaction, predict its rate law:

SOLUTION

Analyze We are given the equation and asked for its rate law, assuming that it is an elementary process.

Plan Because we are assuming that the reaction occurs as a single elementary reaction, we are able to write the rate law using the coefficients for the reactants in the equation as the reaction orders.

Solve The reaction is bimolecular, involving one molecule of H_2 and one molecule of Br_2 . Thus, the rate law is first order in each reactant and second order overall:

$$\text{Rate} = k[\text{H}_2][\text{Br}_2]$$

Comment Experimental studies of this reaction show that the reaction actually has a very different rate law:

$$\text{Rate} = k[\text{H}_2][\text{Br}_2]^{1/2}$$

Because the experimental rate law differs from the one obtained by assuming a single elementary reaction, we can conclude that the mechanism cannot occur by a single elementary step. It must, therefore, involve two or more elementary steps.

PRACTICE EXERCISE

Consider the following reaction: $2 \text{NO}(\text{g}) + \text{Br}_2(\text{g}) \longrightarrow 2 \text{NOBr}(\text{g})$. (a) Write the rate law for the reaction, assuming it involves a single elementary reaction. (b) Is a single-step mechanism likely for this reaction?

Answers: (a) Rate = $k[\text{NO}]^2[\text{Br}_2]$, (b) No, because termolecular reactions are very rare.

The Rate-Determining Step for a Multistep Mechanism

As with the reaction in Sample Exercise 14.13, most reactions occur by mechanisms that involve two or more elementary reactions. Each step of the mechanism has its own rate constant and activation energy. Often one step is much slower than the others, and the overall rate of a reaction cannot exceed the rate of the slowest elementary step. Because the slow step limits the overall reaction rate, it is called the **rate-determining step** (or *rate-limiting step*).

To understand the concept of the rate-determining step for a reaction, consider a toll road with two toll plazas (► FIGURE 14.21). Cars enter the toll road at point 1 and pass through toll plaza A. They then pass an intermediate point 2 before passing through toll plaza B and arriving at point 3. We can envision this trip along the toll road as occurring in two elementary steps:

(a) Cars slowed at toll plaza A, rate-determining step is passage through A

(b) Cars slowed at toll plaza B, rate-determining step is passage through B

◀ **FIGURE 14.21** Rate-determining steps in traffic flow on a toll road.

Now suppose that one or more gates at toll plaza A are malfunctioning, so that traffic backs up behind the gates, as depicted in Figure 14.21(a). The rate at which cars can get to point 3 is limited by the rate at which they can get through the traffic jam at plaza A. Thus, step 1 is the rate-determining step of the journey along the toll road. If, however, all gates at A are functioning but one or more at B are not, traffic flows quickly through A but gets backed up at B, as depicted in Figure 14.21(b). In this case step 2 is the rate-determining step.

In the same way, *the slowest step in a multistep reaction limits the overall rate*. By analogy to Figure 14.21(a), the rate of a fast step following the rate-determining step does not speed up the overall rate. If the slow step is not the first one, as is the case in Figure 14.21(b), the faster preceding steps produce intermediate products that accumulate before being consumed in the slow step. In either case, *the rate-determining step governs the rate law for the overall reaction*.

▲ GIVE IT SOME THOUGHT

Why can't the rate law for a reaction generally be deduced from the balanced equation for the reaction?

Mechanisms with a Slow Initial Step

We can most easily see the relationship between the slow step in a mechanism and the rate law for the overall reaction by considering an example in which the first step in a multistep mechanism is the rate-determining step. Consider the reaction of NO_2 and CO to produce NO and CO_2 (Equation 14.23). Below 225°C , it is found experimentally that the rate law for this reaction is second order in NO_2 and zero order in CO : $\text{Rate} = k[\text{NO}_2]^2$. Can we propose a reaction mechanism consistent with this rate law? Consider the two-step mechanism:*

Step 2 is much faster than step 1; that is, $k_2 \gg k_1$, telling us that the intermediate $\text{NO}_3(\text{g})$ is slowly produced in step 1 and immediately consumed in step 2.

*Note the rate constants k_1 and k_2 written above the reaction arrows. The subscript on each rate constant identifies the elementary step involved. Thus, k_1 is the rate constant for step 1, and k_2 is the rate constant for step 2. A negative subscript refers to the rate constant for the reverse of an elementary step. For example, k_{-1} is the rate constant for the reverse of the first step.

Because step 1 is slow and step 2 is fast, step 1 is the rate-determining step. Thus, the rate of the overall reaction depends on the rate of step 1, and the rate law of the overall reaction equals the rate law of step 1. Step 1 is a bimolecular process that has the rate law

$$\text{Rate} = k_1[\text{NO}_2]^2$$

Thus, the rate law predicted by this mechanism agrees with the one observed experimentally. The reactant CO is absent from the rate law because it reacts in a step that follows the rate-determining step.

A scientist would not, at this point, say that we have “proved” that this mechanism is correct. All we can say is that the rate law predicted by the mechanism is *consistent with experiment*. There could easily be a different sequence of steps that leads to the same rate law. If, however, the predicted rate law of the proposed mechanism disagrees with experiment, we know for certain that the mechanism cannot be correct.

SAMPLE EXERCISE 14.14 Determining the Rate Law for a Multistep Mechanism

The decomposition of nitrous oxide, N_2O , is believed to occur by a two-step mechanism:

(a) Write the equation for the overall reaction. (b) Write the rate law for the overall reaction.

SOLUTION

Analyze Given a multistep mechanism with the relative speeds of the steps, we are asked to write the overall reaction and the rate law for that overall reaction.

Plan (a) Find the overall reaction by adding the elementary steps and eliminating the intermediates. (b) The rate law for the overall reaction will be that of the slow, rate-determining step.

Solve (a) Adding the two elementary reactions gives

Omitting the intermediate, $\text{O}(\text{g})$, which occurs on both sides of the equation, gives the overall reaction:

(b) The rate law for the overall reaction is just the rate law for the slow, rate-determining elementary reaction. Because that slow step is a unimolecular elementary reaction, the rate law is first order:

$$\text{Rate} = k[\text{N}_2\text{O}]$$

PRACTICE EXERCISE

Ozone reacts with nitrogen dioxide to produce dinitrogen pentoxide and oxygen:

The reaction is believed to occur in two steps:

The experimental rate law is $\text{rate} = k[\text{O}_3][\text{NO}_2]$. What can you say about the relative rates of the two steps of the mechanism?

Answer: Because the rate law conforms to the molecularity of the first step, that must be the rate-determining step. The second step must be much faster than the first one.

Mechanisms with a Fast Initial Step

It is less straightforward to derive the rate law for a mechanism in which an intermediate is a reactant in the rate-determining step. This situation arises in multistep mechanisms when the first step is fast and therefore *not* the rate-determining step. Let's consider one example: the gas-phase reaction of nitric oxide (NO) with bromine (Br_2):

The experimentally determined rate law for this reaction is second order in NO and first order in Br₂:

$$\text{Rate} = k[\text{NO}]^2[\text{Br}_2] \quad [14.25]$$

We seek a reaction mechanism that is consistent with this rate law. One possibility is that the reaction occurs in a single termolecular step:

As noted in Practice Exercise 14.13, this does not seem likely because termolecular processes are so rare.

GIVE IT SOME THOUGHT

Why are termolecular elementary steps rare in gas-phase reactions?

Let's consider an alternative mechanism that does not involve a termolecular step:

In this mechanism, step 1 involves two processes: a forward reaction and its reverse.

Because step 2 is the rate-determining step, the rate law for that step governs the rate of the overall reaction:

$$\text{Rate} = k_2[\text{NOBr}_2][\text{NO}] \quad [14.28]$$

However, NOBr₂ is an intermediate generated in the forward reaction of step 1. Intermediates are usually unstable and have a low, unknown concentration. Thus, the rate law of Equation 14.28 depends on the unknown concentration of an intermediate. This is not desirable. Instead, in general, we want to express the rate law for any reaction in terms of the reactants, or the products if necessary, of the reaction.

With the aid of some assumptions, we can express the concentration of the intermediate NOBr₂ in terms of the concentrations of the starting reactants NO and Br₂. We first assume that NOBr₂ is unstable and does not accumulate to any significant extent in the reaction mixture. Once formed, NOBr₂ can be consumed either by reacting with NO to form NOBr or by re-forming NO and Br₂. The first of these possibilities is step 2 of our alternative mechanism, a slow process. The second is the reverse of step 1, a unimolecular process:

Because step 2 is slow, we assume that most of the NOBr₂ falls apart according to this reaction. Thus, we have both the forward and reverse reactions of step 1 occurring much faster than step 2. Because they occur rapidly relative to step 2, the forward and reverse reactions of step 1 establish an equilibrium. As in any other dynamic equilibrium, the rate of the forward reaction equals that of the reverse reaction:

$$\begin{array}{ccc} k_1[\text{NO}][\text{Br}_2] & = & k_{-1}[\text{NOBr}_2] \\ \text{Rate of forward reaction} & & \text{Rate of reverse reaction} \end{array}$$

Solving for [NOBr₂], we have

$$[\text{NOBr}_2] = \frac{k_1}{k_{-1}} [\text{NO}][\text{Br}_2]$$

Substituting this relationship into Equation 14.28, we have

$$\text{Rate} = k_2 \frac{k_1}{k_{-1}} [\text{NO}][\text{Br}_2][\text{NO}] = k[\text{NO}]^2[\text{Br}_2]$$

where the experimental rate constant k equals k_2k_1/k_{-1} . This expression is consistent with the experimental rate law (Equation 14.25). Thus, our alternative mechanism

(Equation 14.27), which involves two steps but only unimolecular and bimolecular processes, is far more probable than the single-step termolecular mechanism of Equation 14.26.

In general, *whenever a fast step precedes a slow one, we can solve for the concentration of an intermediate by assuming that an equilibrium is established in the fast step.*

SAMPLE EXERCISE 14.15 Deriving the Rate Law for a Mechanism with a Fast Initial Step

Show that the following mechanism for Equation 14.24 also produces a rate law consistent with the experimentally observed one:

SOLUTION

Analyze We are given a mechanism with a fast initial step and asked to write the rate law for the overall reaction.

Plan The rate law of the slow elementary step in a mechanism determines the rate law for the overall reaction. Thus, we first write the rate law based on the molecularity of the slow step. In this case the slow step involves the intermediate N_2O_2 as a reactant. Experimental rate laws, however, do not contain the concentrations of intermediates; instead they are expressed in terms of the concentrations of starting substances. Thus, we must relate the concentration of N_2O_2 to the concentration of NO by assuming that an equilibrium is established in the first step.

Solve The second step is rate determining, so the overall rate is

$$\text{Rate} = k_2[\text{N}_2\text{O}_2][\text{Br}_2]$$

We solve for the concentration of the intermediate N_2O_2 by assuming that an equilibrium is established in step 1; thus, the rates of the forward and reverse reactions in step 1 are equal:

$$k_1[\text{NO}]^2 = k_{-1}[\text{N}_2\text{O}_2]$$

Solving for the concentration of the intermediate, N_2O_2 , gives

$$[\text{N}_2\text{O}_2] = \frac{k_1}{k_{-1}}[\text{NO}]^2$$

Substituting this expression into the rate expression gives

$$\text{Rate} = k_2 \frac{k_1}{k_{-1}}[\text{NO}]^2[\text{Br}_2] = k[\text{NO}]^2[\text{Br}_2]$$

Thus, this mechanism also yields a rate law consistent with the experimental one.

PRACTICE EXERCISE

The first step of a mechanism involving the reaction of bromine is

What is the expression relating the concentration of $\text{Br}(g)$ to that of $\text{Br}_2(g)$?

Answer: $[\text{Br}] = \left(\frac{k_1}{k_{-1}} [\text{Br}_2] \right)^{1/2}$

So far we have considered only three reaction mechanisms: one for a reaction that occurs in a single elementary step and two for simple multistep reactions where there is one rate-determining step. There are other more complex mechanisms, however. If you take a biochemistry class, for example, you will learn about cases in which you have to assume that the concentration of an intermediate cannot be neglected in deriving the rate law. Furthermore, some mechanisms require a large number of steps, sometimes 35 or more, to arrive at a rate law that agrees with experimental data!

14.7 CATALYSIS

A **catalyst** is a substance that changes the speed of a chemical reaction without undergoing a permanent chemical change itself. Most reactions in the body, the atmosphere, and the oceans occur with the help of catalysts. Much industrial chemical research is devoted to the search for more effective catalysts for reactions of commercial importance. Extensive research efforts also are devoted to finding means of inhibiting or removing certain catalysts that promote undesirable reactions, such as those that corrode metals, age our bodies, and cause tooth decay.

Homogeneous Catalysis

A catalyst that is present in the same phase as the reactants in a reaction mixture is called a **homogeneous catalyst**. Examples abound both in solution and in the gas phase. Consider, for example, the decomposition of aqueous hydrogen peroxide, $\text{H}_2\text{O}_2(aq)$, into water and oxygen:

In the absence of a catalyst, this reaction occurs extremely slowly. Many substances are capable of catalyzing the reaction, however, including bromide ion, which reacts with hydrogen peroxide in acidic solution, forming aqueous bromine and water (▼ FIGURE 14.22):

▲ FIGURE 14.22 Homogeneous catalysis. Effect of catalyst on the speed of hydrogen peroxide decomposition to water and oxygen gas.

If this were the complete reaction, bromide ion would not be a catalyst because it undergoes chemical change during the reaction. However, hydrogen peroxide also reacts with the $\text{Br}_2(\text{aq})$ generated in Equation 14.30:

The sum of Equations 14.30 and 14.31 is just Equation 14.29, a result which you can check for yourself.

When the H_2O_2 has been completely decomposed, we are left with a colorless solution of $\text{Br}^-(\text{aq})$, which means that this ion is indeed a catalyst of the reaction because it speeds up the reaction without itself undergoing any net change. In contrast, Br_2 is an intermediate because it is first formed (Equation 14.30) and then consumed (Equation 14.31). Neither the catalyst nor the intermediate appears in the equation for the overall reaction. Notice, however, that *the catalyst is there at the start of the reaction, whereas the intermediate is formed during the course of the reaction.*

How does a catalyst work? If we think about the general form of rate laws (Equation 14.7, $\text{rate} = k[\text{A}]^m[\text{B}]^n$), we must conclude that the catalyst must affect the numerical value of k , the rate constant. On the basis of the Arrhenius equation (Equation 14.19, $k = Ae^{-E_a/RT}$), k is determined by the activation energy (E_a) and the frequency factor (A). A catalyst may affect the rate of reaction by altering the value of either E_a or A . We can envision this happening in two ways: The catalyst could provide a new mechanism for the reaction that has an E_a value lower than the E_a value for the uncatalyzed reaction, or the catalyst could assist in the orientation of reactants and so increase A . The most dramatic catalytic effects come from lowering E_a . As a general rule, *a catalyst lowers the overall activation energy for a chemical reaction.*

A catalyst can lower the activation energy for a reaction by providing a different mechanism for the reaction. In the decomposition of hydrogen peroxide, for example, two successive reactions of H_2O_2 , first with bromide and then with bromine, take place. Because these two reactions together serve as a catalytic pathway for hydrogen peroxide decomposition, *both* of

them must have significantly lower activation energies than the uncatalyzed decomposition (◀ FIGURE 14.23).

GO FIGURE

Where are the intermediates and transition states in this diagram?

▲ FIGURE 14.23 Energy profiles for the uncatalyzed and bromide-catalyzed decomposition of H_2O_2 .

GIVE IT SOME THOUGHT

How does a catalyst increase the rate of a reaction?

Heterogeneous Catalysis

A **heterogeneous catalyst** is one that exists in a phase different from the phase of the reactant molecules, usually as a solid in contact with either gaseous reactants or with reactants in a liquid solution. Many industrially important reactions are catalyzed by the surfaces of solids. For example, hydrocarbon molecules are rearranged to form gasoline with the aid of what are called “cracking” catalysts. Heterogeneous catalysts are often composed of metals or metal oxides. Because the catalyzed reaction occurs on the surface, special methods are often used to prepare catalysts so that they have very large surface areas.

The initial step in heterogeneous catalysis is usually **adsorption** of reactants. *Adsorption* refers to the binding of molecules to a surface, whereas *absorption* refers to the uptake of molecules into the interior of a substance. ∞ (Section 13.6) Adsorption occurs because the atoms or ions at the surface of a solid are extremely reactive. Unlike their counterparts in the interior of the substance, surface atoms and ions have unused bonding capacity that can be used to bond molecules from the gas or solution phase to the surface of the solid.

▲ **FIGURE 14.24** Heterogeneous catalysis. Mechanism for reaction of ethylene with hydrogen on a catalytic surface.

The reaction of hydrogen gas with ethylene gas to form ethane gas provides an example of heterogeneous catalysis:

Even though this reaction is exothermic, it occurs very slowly in the absence of a catalyst. In the presence of a finely powdered metal, however, such as nickel, palladium, or platinum, the reaction occurs easily at room temperature via the mechanism diagrammed in ▲ **FIGURE 14.24**. Both ethylene and hydrogen are adsorbed on the metal surface. Upon adsorption, the H—H bond of H_2 breaks, leaving two H atoms initially bonded to the metal surface but relatively free to move. When a hydrogen encounters an adsorbed ethylene molecule, it can form a σ bond to one of the carbon atoms, effectively destroying the C—C π bond and leaving an *ethyl group* (C_2H_5) bonded to the surface via a metal-to-carbon σ bond. This σ bond is relatively weak, so when the other carbon atom also encounters a hydrogen atom, a sixth C—H σ bond is readily formed, and an ethane molecule (C_2H_6) is released from the metal surface.

▲ GIVE IT SOME THOUGHT

How does a homogeneous catalyst compare with a heterogeneous one regarding the ease of recovery of the catalyst from the reaction mixture?

Enzymes

The human body is characterized by an extremely complex system of interrelated chemical reactions, all of which must occur at carefully controlled rates to maintain life. A large number of marvelously efficient biological catalysts known as **enzymes** are necessary for many of these reactions to occur at suitable rates. Most enzymes are large

CHEMISTRY PUT TO WORK

Catalytic Converters

Heterogeneous catalysis plays a major role in the fight against urban air pollution. Two components of automobile exhausts that help form photochemical smog are nitrogen oxides and unburned hydrocarbons.

In addition, automobile exhaust may contain considerable quantities of carbon monoxide. Even with the most careful attention to engine design, it is impossible under normal driving conditions to reduce the quantity of these pollutants to an acceptable level in the exhaust gases. It is therefore necessary to remove them from the exhaust before they are vented to the air. This removal is accomplished in the *catalytic converter*.

The catalytic converter, which is part of an automobile's exhaust system, must perform two functions: (1) oxidation of CO and unburned hydrocarbons (C_xH_y) to carbon dioxide and water, and (2) reduction of nitrogen oxides to nitrogen gas:

These two functions require different catalysts, so the development of a successful catalyst system is a difficult challenge. The catalysts must be effective over a wide range of operating temperatures. They must continue to be active despite the fact that various components of the exhaust can block the active sites of the catalyst. And the catalysts must be sufficiently rugged to withstand exhaust gas turbulence and the mechanical shocks of driving under various conditions for thousands of miles.

Catalysts that promote the combustion of CO and hydrocarbons are, in general, the transition-metal oxides and the noble metals. These materials are supported on a structure (► **FIGURE 14.25**) that allows the best possible contact between the flowing exhaust gas and the catalyst surface. A honeycomb structure made from alumina (Al_2O_3) and impregnated with the catalyst is employed. Such catalysts operate by first adsorbing oxygen gas present in the exhaust gas. This adsorption

weakens the O—O bond in O_2 , so that oxygen atoms are available for reaction with adsorbed CO to form CO_2 . Hydrocarbon oxidation probably proceeds somewhat similarly, with the hydrocarbons first being adsorbed followed by rupture of a C—H bond.

Transition-metal oxides and noble metals are also the most effective catalysts for reduction of NO to N_2 and O_2 . The catalysts that are most effective in one reaction, however, are usually much less effective in the other. It is therefore necessary to have two catalytic components.

Catalytic converters contain remarkably efficient heterogeneous catalysts. The automotive exhaust gases are in contact with the catalyst for only 100 to 400 ms, but in this very short time, 96% of the hydrocarbons and CO is converted to CO_2 and H_2O , and the emission of nitrogen oxides is reduced by 76%.

There are costs as well as benefits associated with the use of catalytic converters, one being that some of the metals are very expensive. Catalytic converters currently account for about 35% of the platinum, 65% of the palladium, and 95% of the rhodium used annually. All of these metals, which come mainly from Russia and South Africa, can be far more expensive than gold.

RELATED EXERCISES: 14.64, 14.87, 14.88

▲ **FIGURE 14.25** Cross section of a catalytic converter.

▲ **FIGURE 14.26** Enzymes speed up reactions.

protein molecules with molecular weights ranging from about 10,000 to about 1 million amu. They are very selective in the reactions they catalyze, and some are absolutely specific, operating for only one substance in only one reaction. The decomposition of hydrogen peroxide, for example, is an important biological process. Because hydrogen peroxide is strongly oxidizing, it can be physiologically harmful. For this reason, the blood and liver of mammals contain an enzyme, *catalase*, that catalyzes the decomposition of hydrogen peroxide into water and oxygen (Equation 14.29). ◀ **FIGURE 14.26** shows the dramatic acceleration of this chemical reaction by the catalase in beef liver.

GO FIGURE

Which molecules must bind more tightly to the active site, substrates or products?

▲ FIGURE 14.27 Lock-and-key model for enzyme action.

The reaction any given enzyme catalyzes takes place at a specific location in the enzyme, the **active site**. The substances that react at this site are called **substrates**. The **lock-and-key model** provides a simple explanation for the specificity of an enzyme (▲ FIGURE 14.27). The substrate is pictured as fitting neatly into the active site, much like a key fits into a lock. Although this model oversimplifies the situation, since enzymes can “wobble” to adjust the shape and size of the active site, the lock-and-key model is a good place to start understanding enzyme activity.

► FIGURE 14.28 shows a model of the enzyme lysozyme without and with a bound substrate molecule.

The combination of enzyme and substrate is called the *enzyme-substrate complex*. Although Figure 14.27 shows both the active site and its substrate as having a fixed shape, the active site is often fairly flexible and so may change shape as it binds the substrate. The binding between substrate and active site involves dipole–dipole attractions, hydrogen bonds, and dispersion forces. ∞ (Section 11.2)

As substrate molecules enter the active site, they are somehow activated so that they are capable of reacting rapidly. This activation process may occur, for example, by the withdrawal or donation of electron density from a particular bond or group of atoms in the enzyme’s active site. In addition, the substrate may become distorted in the process of fitting into the active site and made more reactive. Once the reaction occurs, the products depart from the active site, allowing another substrate molecule to enter.

The activity of an enzyme is destroyed if some molecule other than the substrate specific to that enzyme binds to the active site and blocks entry of the substrate. Such substances are called *enzyme inhibitors*. Nerve poisons and certain toxic metal ions, such as lead and mercury, are believed to act in this way to inhibit enzyme activity. Some other poisons act by attaching elsewhere on the enzyme, thereby distorting the active site so that the substrate no longer fits.

Enzymes are enormously more efficient than nonbiochemical catalysts. The number of individual catalyzed reaction events occurring at a particular active site, called the *turnover number*, is generally in the range of 10^3 to 10^7 per second. Such large turnover numbers correspond to very low activation energies. Compared with a simple chemical catalyst, enzymes can increase the rate constant for a given reaction by a million-fold or more.

GIVE IT SOME THOUGHT

Is it reasonable to say that enzymes stabilize the transition state for a reaction? Explain your answer.

▲ FIGURE 14.28 Molecular model of lysozyme without and with a bound substrate molecule (yellow).

CHEMISTRY AND LIFE

NITROGEN FIXATION AND NITROGENASE

Nitrogen is one of the most essential elements in living organisms, found in many compounds vital to life, including proteins, nucleic acids, vitamins, and hormones. Nitrogen is continually cycling

▲ FIGURE 14.29 Simplified picture of the nitrogen cycle.

through the biosphere in various forms, as shown in ◀ FIGURE 14.29. For example, certain microorganisms convert the nitrogen in animal waste and dead plants and animals into $N_2(g)$, which then returns to the atmosphere. For the food chain to be sustained, there must be a means of converting atmospheric $N_2(g)$ in a form plants can use. For this reason, if a chemist were asked to name the most important chemical reaction in the world, she might easily say *nitrogen fixation*, the process by which atmospheric $N_2(g)$ is converted into compounds suitable for plant use. Some fixed nitrogen results from the action of lightning on the atmosphere, and some is produced industrially using a process we will discuss in Chapter 15. About 60% of fixed nitrogen, however, is a consequence of the action of the remarkable and complex enzyme *nitrogenase*. This enzyme is *not* present in humans or other animals; rather, it is found in bacteria that live in the root nodules of certain plants, such as the legumes clover and alfalfa.

Nitrogenase converts N_2 into NH_3 , a process that, in the absence of a catalyst, has a very large activation energy. This process is a *reduction* reaction in which the oxidation state of N is reduced from 0 in N_2 to -3 in NH_3 . The mechanism by which nitrogenase reduces N_2 is not fully understood. Like many other enzymes, including catalase, the active site of nitrogenase contains transition-metal atoms; such enzymes are called *metalloenzymes*. Because transition metals can readily change oxidation state, metalloenzymes are especially useful for effecting transformations in which substrates are either oxidized or reduced.

It has been known for nearly 30 years that a portion of nitrogenase contains iron and molybdenum atoms. This portion, called the *FeMo-cofactor*, is thought to serve as the active site of the enzyme. The FeMo-cofactor of nitrogenase is a cluster of seven Fe atoms and one Mo atom, all linked by sulfur atoms (◀ FIGURE 14.30).

It is one of the wonders of life that simple bacteria can contain beautifully complex and vitally important enzymes such as nitrogenase. Because of this enzyme, nitrogen is continually cycled between its comparatively inert role in the atmosphere and its critical role in living organisms. Without nitrogenase, life as we know it could not exist on Earth.

RELATED EXERCISES: 14.91, 14.126

◀ FIGURE 14.30 The FeMo-cofactor of nitrogenase. Nitrogenase is found in nodules in the roots of certain plants, such as the white clover roots shown at the left. The cofactor, which is thought to be the active site of the enzyme, contains seven Fe atoms and one Mo atom, linked by sulfur atoms. The molecules on the outside of the cofactor connect it to the rest of the protein.

SAMPLE INTEGRATIVE EXERCISE Putting Concepts Together

Formic acid (HCOOH) decomposes in the gas phase at elevated temperatures as follows:

The uncatalyzed decomposition reaction is determined to be first order. A graph of the partial pressure of HCOOH versus time for decomposition at 838 K is shown as the red curve in ► **FIGURE 14.31**. When a small amount of solid ZnO is added to the reaction chamber, the partial pressure of acid versus time varies as shown by the blue curve in Figure 14.31.

- Estimate the half-life and first-order rate constant for formic acid decomposition.
- What can you conclude from the effect of added ZnO on the decomposition of formic acid?
- The progress of the reaction was followed by measuring the partial pressure of formic acid vapor at selected times. Suppose that, instead, we had plotted the concentration of formic acid in units of mol/L. What effect would this have had on the calculated value of k ?
- The pressure of formic acid vapor at the start of the reaction is 3.00×10^2 torr. Assuming constant temperature and ideal-gas behavior, what is the pressure in the system at the end of the reaction? If the volume of the reaction chamber is 436 cm^3 , how many moles of gas occupy the reaction chamber at the end of the reaction?
- The standard heat of formation of formic acid vapor is $\Delta H_f^\circ = -378.6 \text{ kJ/mol}$. Calculate ΔH° for the overall reaction. If the activation energy (E_a) for the reaction is 184 kJ/mol , sketch an approximate energy profile for the reaction, and label E_a , ΔH° , and the transition state.

SOLUTION

(a) The initial pressure of HCOOH is 3.00×10^2 torr. On the graph we move to the level at which the partial pressure of HCOOH is 1.50×10^2 torr, half the initial value. This corresponds to a time of about 6.60×10^2 s, which is therefore the half-life. The first-order rate constant is given by Equation 14.15: $k = 0.693/t_{1/2} = 0.693/660 \text{ s} = 1.05 \times 10^{-3} \text{ s}^{-1}$.

(b) The reaction proceeds much more rapidly in the presence of solid ZnO, so the surface of the oxide must be acting as a catalyst for the decomposition of the acid. This is an example of heterogeneous catalysis.

(c) If we had graphed the concentration of formic acid in units of moles per liter, we would still have determined that the half-life for decomposition is 660 s, and we would have computed the same value for k . Because the units for k are s^{-1} , the value for k is independent of the units used for concentration.

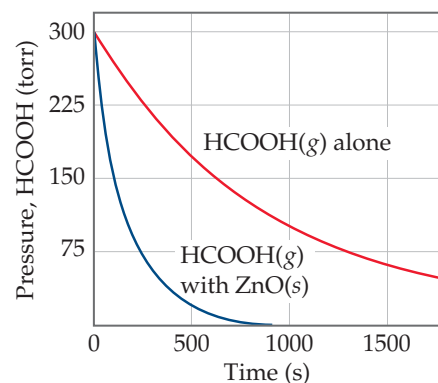

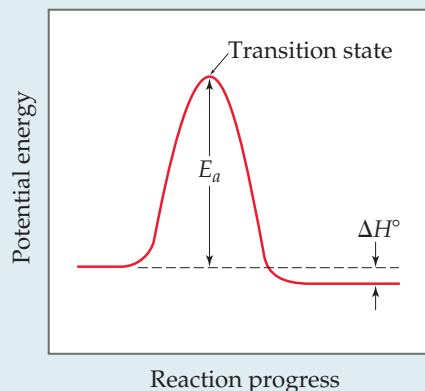

(d) According to the stoichiometry of the reaction, two moles of product are formed for each mole of reactant. When reaction is completed, therefore, the pressure will be 600 torr, just twice the initial pressure, assuming ideal-gas behavior. (Because we are working at quite high temperature and fairly low gas pressure, assuming ideal-gas behavior is reasonable.) The number of moles of gas present can be calculated using the ideal-gas equation: ∞ (Section 10.4)

$$n = \frac{PV}{RT} = \frac{(600/760 \text{ atm})(0.436 \text{ L})}{(0.08206 \text{ L}\cdot\text{atm/mol}\cdot\text{K})(838 \text{ K})} = 5.00 \times 10^{-3} \text{ mole}$$

(e) We first calculate the overall change in energy, ΔH° (∞ Section 5.7 and Appendix C), as in

$$\begin{aligned} \Delta H^\circ &= \Delta H_f^\circ(\text{CO}_2(g)) + \Delta H_f^\circ(\text{H}_2(g)) - \Delta H_f^\circ(\text{HCOOH}(g)) \\ &= -393.5 \text{ kJ/mol} + 0 - (-378.6 \text{ kJ/mol}) \\ &= -14.9 \text{ kJ/mol} \end{aligned}$$

From this and the given value for E_a , we can draw an approximate energy profile for the reaction, in analogy to Figure 14.17.

► **FIGURE 14.31** Variation in pressure of HCOOH(g) as a function of time at 838 K.

CHAPTER SUMMARY AND KEY TERMS

INTRODUCTION AND SECTION 14.1 **Chemical kinetics** is the area of chemistry in which **reaction rates** are studied. Factors that affect reaction rate are the physical state of the reactants; concentration; temperature; and the presence of catalysts.

SECTION 14.2 Reaction rate are usually expressed as changes in concentration per unit time: Typically, for reactions in solution, rates are given in units of molarity per second M/s . For most reactions, a plot of molarity versus time shows that the rate slows down as the reaction proceeds. The **instantaneous rate** is the slope of a line drawn tangent to the concentration-versus-time curve at a specific time. Rates can be written in terms of the appearance of products or the disappearance of reactants; the stoichiometry of the reaction dictates the relationship between rates of appearance and disappearance.

SECTION 14.3 The quantitative relationship between rate and concentration is expressed by a **rate law**, which usually has the following form:

$$\text{Rate} = k[\text{reactant 1}]^m[\text{reactant 2}]^n \dots$$

The constant k in the rate law is called the **rate constant**; the exponents m , n , and so forth are called **reaction orders** for the reactants. The sum of the reaction orders gives the **overall reaction order**. Reaction orders must be determined experimentally. The units of the rate constant depend on the overall reaction order. For a reaction in which the overall reaction order is 1, k has units of s^{-1} ; for one in which the overall reaction order is 2, k has units of $M^{-1} s^{-1}$. Spectroscopy is one technique that can be used to monitor the course of a reaction. According to Beer's law, the absorption of electromagnetic radiation by a substance at a particular wavelength is directly proportional to its concentration.

SECTION 14.4 Rate laws can be used to determine the concentrations of reactants or products at any time during a reaction. In a **first-order reaction** the rate is proportional to the concentration of a single reactant raised to the first power: $\text{Rate} = k[A]$. In such cases the integrated form of the rate law is $\ln[A]_t = -kt + \ln[A]_0$, where $[A]_t$ is the concentration of reactant A at time t , k is the rate constant, and $[A]_0$ is the initial concentration of A. Thus, for a first-order reaction, a graph of $\ln[A]$ versus time yields a straight line of slope $-k$.

A **second-order reaction** is one for which the overall reaction order is 2. If a second-order rate law depends on the concentration of only one reactant, then $\text{rate} = k[A]^2$, and the time dependence of $[A]$ is given by the integrated form of the rate law: $1/[A]_t = 1/[A]_0 + kt$. In this case a graph of $1/[A]_t$ versus time yields a straight line. A **zero-order reaction** is one for which the overall reaction order is 0. $\text{Rate} = k$ if the reaction is zero order.

The **half-life** of a reaction, $t_{1/2}$, is the time required for the concentration of a reactant to drop to one-half of its original value. For a first-order reaction, the half-life depends only on the rate constant and not on the initial concentration: $t_{1/2} = 0.693/k$. The half-life of a second-order reaction depends on both the rate constant and the initial concentration of A: $t_{1/2} = 1/k[A]_0$.

SECTION 14.5 The **collision model**, which assumes that reactions occur as a result of collisions between molecules, helps explain why the magnitudes of rate constants increase with increasing temperature.

The greater the kinetic energy of the colliding molecules, the greater is the energy of collision. The minimum energy required for a reaction to occur is called the **activation energy**, E_a . A collision with energy E_a or greater can cause the atoms of the colliding molecules to reach the **activated complex** (or **transition state**), which is the highest energy arrangement in the pathway from reactants to products. Even if a collision is energetic enough, it may not lead to reaction; the reactants must also be correctly oriented relative to one another in order for a collision to be effective.

Because the kinetic energy of molecules depends on temperature, the rate constant of a reaction is very dependent on temperature. The relationship between k and temperature is given by the **Arrhenius equation**: $k = Ae^{-E_a/RT}$. The term A is called the **frequency factor**; it relates to the number of collisions that are favorably oriented for reaction. The Arrhenius equation is often used in logarithmic form: $\ln k = \ln A - E_a/RT$. Thus, a graph of $\ln k$ versus $1/T$ yields a straight line with slope $-E_a/R$.

SECTION 14.6 A **reaction mechanism** details the individual steps that occur in the course of a reaction. Each of these steps, called **elementary reactions**, has a well-defined rate law that depends on the number of molecules (the **molecularity**) of the step. Elementary reactions are defined as either **unimolecular**, **bimolecular**, or **termolecular**, depending on whether one, two, or three reactant molecules are involved, respectively. Termolecular elementary reactions are very rare. Unimolecular, bimolecular, and termolecular reactions follow rate laws that are first order overall, second order overall, and third order overall, respectively. Many reactions occur by a multistep mechanism, involving two or more elementary reactions, or steps. An **intermediate** is produced in one elementary step, is consumed in a later elementary step, and therefore does not appear in the overall equation for the reaction. When a mechanism has several elementary steps, the overall rate is limited by the slowest elementary step, called the **rate-determining step**. A fast elementary step that follows the rate-determining step will have no effect on the rate law of the reaction. A fast step that precedes the rate-determining step often creates an equilibrium that involves an intermediate. For a mechanism to be valid, the rate law predicted by the mechanism must be the same as that observed experimentally.

SECTION 14.7 A **catalyst** is a substance that increases the rate of a reaction without undergoing a net chemical change itself. It does so by providing a different mechanism for the reaction, one that has a lower activation energy. A **homogeneous catalyst** is one that is in the same phase as the reactants. A **heterogeneous catalyst** has a different phase from the reactants. Finely divided metals are often used as heterogeneous catalysts for solution- and gas-phase reactions. Reacting molecules can undergo binding, or **adsorption**, at the surface of the catalyst. The adsorption of a reactant at specific sites on the surface makes bond breaking easier, lowering the activation energy. Catalysis in living organisms is achieved by **enzymes**, large protein molecules that usually catalyze a very specific reaction. The specific reactant molecules involved in an enzymatic reaction are called **substrates**. The site of the enzyme where the catalysis occurs is called the **active site**. In the **lock-and-key model** for enzyme catalysis, substrate molecules bind very specifically to the active site of the enzyme, after which they can undergo reaction.

KEY SKILLS

- Understand the factors that affect the rate of chemical reactions. (Section 14.1)
- Determine the rate of a reaction given time and concentration. (Section 14.2)
- Relate the rate of formation of products and the rate of disappearance of reactants given the balanced chemical equation for the reaction. (Section 14.2)
- Understand the form and meaning of a rate law including the ideas of reaction order and rate constant. (Section 14.3)
- Determine the rate law and rate constant for a reaction from a series of experiments given the measured rates for various concentrations of reactants. (Section 14.3)
- Use the integrated form of a rate law to determine the concentration of a reactant at a given time. (Section 14.4)
- Explain how the activation energy affects a rate and be able to use the Arrhenius equation. (Section 14.5)
- Predict a rate law for a reaction having a multistep mechanism given the individual steps in the mechanism. (Section 14.6)
- Explain how a catalyst works. (Section 14.7)

KEY EQUATIONS

- $\text{Rate} = -\frac{1}{a} \frac{\Delta[A]}{\Delta t} = -\frac{1}{b} \frac{\Delta[B]}{\Delta t} = \frac{1}{c} \frac{\Delta[C]}{\Delta t} = \frac{1}{d} \frac{\Delta[D]}{\Delta t}$ [14.4] Relating rates to the components of the balanced chemical equation $aA + bB \longrightarrow cC + dD$
- $\text{Rate} = k[A]^m[B]^n$ [14.7] General form of a rate law for the reaction $A + B \longrightarrow \text{products}$
- $\ln[A]_t - \ln[A]_0 = -kt$ or $\ln \frac{[A]_t}{[A]_0} = -kt$ [14.12] The integrated form of a first-order rate law for the reaction $A \longrightarrow \text{products}$
- $\frac{1}{[A]_t} = kt + \frac{1}{[A]_0}$ [14.14] The integrated form of the second-order rate law for the reaction $A \longrightarrow \text{products}$
- $t_{1/2} = \frac{0.693}{k}$ [14.15] Relating the half-life and rate constant for a first-order reaction
- $k = Ae^{-E_a/RT}$ [14.19] The Arrhenius equation, which expresses how the rate constant depends on temperature
- $\ln k = -\frac{E_a}{RT} + \ln A$ [14.20] Linear form of the Arrhenius equation

EXERCISES

VISUALIZING CONCEPTS

- 14.1** For which one of the following vessels for the reaction $A + B \longrightarrow C$ is the reaction the fastest? Assume all vessels are at the same temperature. [Section 4.1]

- 14.2** Consider the following graph of the concentration of a substance over time. (a) Is X a reactant or product of the reaction? (b) Is the reaction speeding up, slowing down, or not changing its rate as time progresses? (c) Why is the average rate of the reaction different between points 1 and 2 than between points 2 and 3? [Section 14.2]

- 14.3 You study the rate of a reaction, measuring both the concentration of the reactant and the concentration of the product as a function of time, and obtain the following results:

Which chemical equation is consistent with these data: (a) $A \rightarrow B$, (b) $B \rightarrow A$, (c) $A \rightarrow 2B$, (d) $B \rightarrow 2A$? Explain your choice. [Section 14.2]

- 14.4 You perform the reaction $K + L \rightarrow M$, monitor the production of M over time, and then plot this graph from your data:

(a) Is the reaction occurring at a constant rate from $t = 0$ to $t = 15$ min? Explain. (b) Is the reaction completed at $t = 15$ min? Explain.

- 14.5 You perform a series of experiments for the reaction $A \rightarrow B + C$ and find that the rate law has the form $\text{rate} = k[A]^x$. Determine the value of x in each of the following cases: (a) There is no rate change when $[A]_0$ is tripled. (b) The rate increases by a factor of 9 when $[A]_0$ is tripled. (c) When $[A]_0$ is doubled, the rate increases by a factor of 8. [Section 14.3]

- 14.6 The following diagrams represent mixtures of $\text{NO}(g)$ and $\text{O}_2(g)$. These two substances react as follows:

It has been determined experimentally that the rate is second order in NO and first order in O_2 . Based on this fact, which of the following mixtures will have the fastest initial rate? [Section 14.3]

- 14.7 A friend studies a first-order reaction and obtains the following three graphs for experiments done at two different temperatures. (a) Which two graphs represent experiments done at the same temperature? What accounts for the difference in these two graphs? In what way are they the same? (b) Which two graphs represent experiments done with the same starting concentration but at different temperatures? Which graph probably represents the lower temperature? How do you know? [Section 14.4]

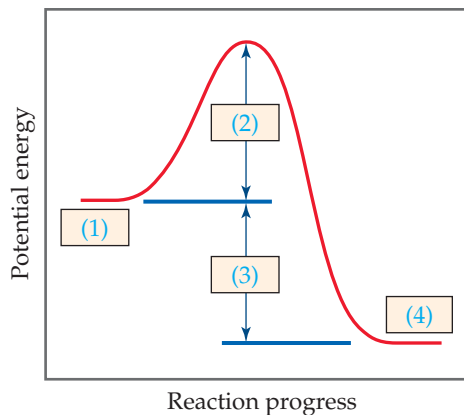

- 14.8 (a) Given the following diagrams at $t = 0$ min and $t = 30$ min, what is the half-life of the reaction if it follows first-order kinetics?

(b) After four half-life periods for a first-order reaction, what fraction of reactant remains? [Section 14.4]

- 14.9 The following diagram shows the reaction profile of a reaction. Label the components indicated by the boxes. [Section 14.5]

- 14.10 You study the effect of temperature on the rate of two reactions and graph the natural logarithm of the rate constant for each reaction as a function of $1/T$. How do the two graphs compare (a) if the activation energy of the second reaction is higher than the activation energy of the first reaction but the two reactions have the same frequency factor, and (b) if the frequency factor of the second reaction is higher than the frequency factor of the first reaction but the two reactions have the same activation energy? [Section 14.5]

- 14.11 The following graph shows two different reaction pathways for the same overall reaction at the same temperature. (a) Which pathway is slower? Why? (b) How can there be two different reaction pathways for the same reaction at the same temperature? Discuss. [Section 14.6]

- 14.12 Consider the diagram that follows, which represents two steps in an overall reaction. The red spheres are oxygen, the blue ones nitrogen, and the green ones fluorine. (a) Write the chemical equation for each step in the reaction. (b) Write the equation for the overall reaction. (c) Identify the intermediate in the mechanism. (d) Write the rate law for the overall reaction if the first step is the slow, rate-determining step. [Section 14.6]

- 14.13 Based on the following reaction profile, how many intermediates are formed in the reaction $A \longrightarrow C$? How many transition states are there? Which step is the fastest? Is the reaction $A \longrightarrow C$ exothermic or endothermic? [Section 14.6]

- 14.14 Draw a possible transition state for the bimolecular reaction depicted here. (The blue spheres are nitrogen atoms, and the red ones are oxygen atoms.) Use dashed lines to represent the bonds that are in the process of being broken or made in the transition state. [Section 14.6]

- 14.15 The following diagram represents an imaginary two-step mechanism. Let the red spheres represent element A, the green ones element B, and the blue ones element C. (a) Write the equation for the net reaction that is occurring. (b) Identify the intermediate. (c) Identify the catalyst. [Sections 14.6 and 14.7]

- 14.16 Draw a graph showing the reaction pathway for an overall exothermic reaction with two intermediates that are produced at different rates. On your graph indicate the reactants, products, intermediates, transition states, and activation energies. [Sections 14.6 and 14.7]

REACTION RATES (sections 14.1 and 14.2)

- 14.17 (a) What is meant by the term *reaction rate*? (b) Name three factors that can affect the rate of a chemical reaction. (c) Is the rate of disappearance of reactants always the same as the rate of appearance of products? Explain.
- 14.18 (a) What are the units usually used to express the rates of reactions occurring in solution? (b) From your everyday experience, give two examples of the effects of temperature on the rates of reactions. (c) What is the difference between average rate and instantaneous rate?
- 14.19 Consider the following hypothetical aqueous reaction: $A(aq) \longrightarrow B(aq)$. A flask is charged with 0.065 mol of A in a total volume of 100.0 mL. The following data are collected:

Time (min)	0	10	20	30	40
Moles of A	0.065	0.051	0.042	0.036	0.031

- (a) Calculate the number of moles of B at each time in the table, assuming that there are no molecules of B at time zero, and that A cleanly converts to B with no intermediates. (b) Calculate the average rate of disappearance of A for each 10-min interval in units of M/s . (c) Between $t = 10$ min and $t = 30$ min, what is the average rate of appearance of B in units of M/s ? Assume that the volume of the solution is constant.

- 14.20 A flask is charged with 0.100 mol of A and allowed to react to form B according to the hypothetical gas-phase reaction $A(g) \longrightarrow B(g)$. The following data are collected:

Time (s)	0	40	80	120	160
Moles of A	0.100	0.067	0.045	0.030	0.020

(a) Calculate the number of moles of B at each time in the table, assuming that A is cleanly converted to B with no intermediates. (b) Calculate the average rate of disappearance of A for each 40-s interval in units of mol/s. (c) What additional information would be needed to calculate the rate in units of concentration per time?

- 14.21** The isomerization of methyl isonitrile (CH_3NC) to acetonitrile (CH_3CN) was studied in the gas phase at 215°C , and the following data were obtained:

Time (s)	$[\text{CH}_3\text{NC}]$ (M)
0	0.0165
2,000	0.0110
5,000	0.00591
8,000	0.00314
12,000	0.00137
15,000	0.00074

(a) Calculate the average rate of reaction, in M/s , for the time interval between each measurement. (b) Calculate the average rate of reaction over the entire time of the data from $t = 0$ to $t = 15,000$ s. (c) Graph $[\text{CH}_3\text{NC}]$ versus time and determine the instantaneous rates in M/s at $t = 5000$ s and $t = 8000$ s.

- 14.22** The rate of disappearance of HCl was measured for the following reaction:

The following data were collected:

Time (min)	$[\text{HCl}]$ (M)
0.0	1.85
54.0	1.58
107.0	1.36
215.0	1.02
430.0	0.580

(a) Calculate the average rate of reaction, in M/s , for the time interval between each measurement. (b) Calculate the average rate of reaction for the entire time for the data from $t = 0.0$ min to $t = 430.0$ min.

(c) Graph $[\text{HCl}]$ versus time and determine the instantaneous rates in M/min and M/s at $t = 75.0$ min and $t = 250$ min.

- 14.23** For each of the following gas-phase reactions, indicate how the rate of disappearance of each reactant is related to the rate of appearance of each product:

- 14.24** For each of the following gas-phase reactions, write the rate expression in terms of the appearance of each product and disappearance of each reactant:

- 14.25** (a) Consider the combustion of $\text{H}_2(g)$: $2 \text{H}_2(g) + \text{O}_2(g) \longrightarrow 2 \text{H}_2\text{O}(g)$. If hydrogen is burning at the rate of 0.48 mol/s, what is the rate of consumption of oxygen? What is the rate of formation of water vapor? (b) The reaction $2 \text{NO}(g) + \text{Cl}_2(g) \longrightarrow 2 \text{NOCl}(g)$ is carried out in a closed vessel. If the partial pressure of NO is decreasing at the rate of 56 torr/min, what is the rate of change of the total pressure of the vessel?

- 14.26** (a) Consider the combustion of ethylene, $\text{C}_2\text{H}_4(g) + 3 \text{O}_2(g) \longrightarrow 2 \text{CO}_2(g) + 2 \text{H}_2\text{O}(g)$. If the concentration of C_2H_4 is decreasing at the rate of 0.036 M/s , what are the rates of change in the concentrations of CO_2 and H_2O ? (b) The rate of decrease in N_2H_4 partial pressure in a closed reaction vessel from the reaction $\text{N}_2\text{H}_4(g) + \text{H}_2(g) \longrightarrow 2 \text{NH}_3(g)$ is 74 torr per hour. What are the rates of change of NH_3 partial pressure and total pressure in the vessel?

RATE LAWS (section 14.3)

- 14.27** A reaction $\text{A} + \text{B} \longrightarrow \text{C}$ obeys the following rate law: $\text{Rate} = k[\text{B}]^2$. (a) If $[\text{A}]$ is doubled, how will the rate change? Will the rate constant change? Explain. (b) What are the reaction orders for A and B? What is the overall reaction order? (c) What are the units of the rate constant?

- 14.28** Consider a hypothetical reaction between A, B, and C that is first order in A, zero order in B, and second order in C. (a) Write the rate law for the reaction. (b) How does the rate change when $[\text{A}]$ is doubled and the other reactant concentrations are held constant? (c) How does the rate change when $[\text{B}]$ is tripled and the other reactant concentrations are held constant? (d) How does the rate change when $[\text{C}]$ is tripled and the other reactant concentrations are held constant? (e) By what factor does the rate change when the concentrations of all three reactants are tripled? (f) By what factor does the rate change when the concentrations of all three reactants are cut in half?

- 14.29** The decomposition reaction of N_2O_5 in carbon tetrachloride is $2 \text{N}_2\text{O}_5 \longrightarrow 4 \text{NO}_2 + \text{O}_2$. The rate law is first order in N_2O_5 . At 64°C the rate constant is $4.82 \times 10^{-3} \text{ s}^{-1}$. (a) Write the rate law for the reaction. (b) What is the rate of reaction when $[\text{N}_2\text{O}_5] = 0.0240$ M ? (c) What happens to the rate when the concentration of N_2O_5 is doubled to 0.0480 M ? (d) What happens to the rate when the concentration of N_2O_5 is halved to 0.0120 M ?

- 14.30** Consider the following reaction:

(a) The rate law for this reaction is first order in H_2 and second order in NO. Write the rate law. (b) If the rate constant for this reaction at 1000 K is $6.0 \times 10^4 \text{ M}^{-2} \text{ s}^{-1}$, what is the reaction rate when $[\text{NO}] = 0.035$ M and $[\text{H}_2] = 0.015$ M ? (c) What is the reaction rate at 1000 K when the concentration of NO is increased to 0.10 M , while the concentration of H_2 is 0.010 M ?

(d) What is the reaction rate at 1000 K if $[\text{NO}]$ is decreased to 0.010 M and $[\text{H}_2]$ is increased to 0.030 M ?

14.31 Consider the following reaction:

The rate law for this reaction is first order in CH_3Br and first order in OH^- . When $[\text{CH}_3\text{Br}]$ is $5.0 \times 10^{-3}\text{ M}$ and $[\text{OH}^-]$ is 0.050 M , the reaction rate at 298 K is 0.0432 M/s . (a) What is the value of the rate constant? (b) What are the units of the rate constant? (c) What would happen to the rate if the concentration of OH^- were tripled? (d) What would happen to the rate if the concentration of both reactants were tripled?

14.32 The reaction between ethyl bromide ($\text{C}_2\text{H}_5\text{Br}$) and hydroxide ion in ethyl alcohol at 330 K, $\text{C}_2\text{H}_5\text{Br}(alc) + \text{OH}^-(alc) \longrightarrow \text{C}_2\text{H}_5\text{OH}(l) + \text{Br}^-(alc)$, is first order each in ethyl bromide and hydroxide ion. When $[\text{C}_2\text{H}_5\text{Br}]$ is 0.0477 M and $[\text{OH}^-]$ is 0.100 M , the rate of disappearance of ethyl bromide is $1.7 \times 10^{-7}\text{ M/s}$. (a) What is the value of the rate constant? (b) What are the units of the rate constant? (c) How would the rate of disappearance of ethyl bromide change if the solution were diluted by adding an equal volume of pure ethyl alcohol to the solution?

14.33 The iodide ion reacts with hypochlorite ion (the active ingredient in chlorine bleaches) in the following way: $\text{OCl}^- + \text{I}^- \longrightarrow \text{OI}^- + \text{Cl}^-$. This rapid reaction gives the following rate data:

$[\text{OCl}^-] (\text{M})$	$[\text{I}^-] (\text{M})$	Initial Rate (M/s)
1.5×10^{-3}	1.5×10^{-3}	1.36×10^{-4}
3.0×10^{-3}	1.5×10^{-3}	2.72×10^{-4}
1.5×10^{-3}	3.0×10^{-3}	2.72×10^{-4}

(a) Write the rate law for this reaction. (b) Calculate the rate constant with proper units. (c) Calculate the rate when $[\text{OCl}^-] = 2.0 \times 10^{-3}\text{ M}$ and $[\text{I}^-] = 5.0 \times 10^{-4}\text{ M}$.

14.34 The reaction $2\text{ClO}_2(aq) + 2\text{OH}^-(aq) \longrightarrow \text{ClO}_3^-(aq) + \text{ClO}_2^-(aq) + \text{H}_2\text{O}(l)$ was studied with the following results:

Experiment	$[\text{ClO}_2] (\text{M})$	$[\text{OH}^-] (\text{M})$	Initial Rate (M/s)
1	0.060	0.030	0.0248
2	0.020	0.030	0.00276
3	0.020	0.090	0.00828

(a) Determine the rate law for the reaction. (b) Calculate the rate constant with proper units. (c) Calculate the rate when $[\text{ClO}_2] = 0.100\text{ M}$ and $[\text{OH}^-] = 0.050\text{ M}$.

14.35 The following data were measured for the reaction $\text{BF}_3(g) + \text{NH}_3(g) \longrightarrow \text{F}_3\text{BNH}_3(g)$:

Experiment	$[\text{BF}_3] (\text{M})$	$[\text{NH}_3] (\text{M})$	Initial Rate (M/s)
1	0.250	0.250	0.2130
2	0.250	0.125	0.1065
3	0.200	0.100	0.0682
4	0.350	0.100	0.1193
5	0.175	0.100	0.0596

(a) What is the rate law for the reaction? (b) What is the overall order of the reaction? (c) Calculate the rate constant with proper units? (d) What is the rate when $[\text{BF}_3] = 0.100\text{ M}$ and $[\text{NH}_3] = 0.500\text{ M}$?

14.36 The following data were collected for the rate of disappearance of NO in the reaction $2\text{NO}(g) + \text{O}_2(g) \longrightarrow 2\text{NO}_2(g)$:

Experiment	$[\text{NO}] (\text{M})$	$[\text{O}_2] (\text{M})$	Initial Rate (M/s)
1	0.0126	0.0125	1.41×10^{-2}
2	0.0252	0.0125	5.64×10^{-2}
3	0.0252	0.0250	1.13×10^{-1}

(a) What is the rate law for the reaction? (b) What are the units of the rate constant? (c) What is the average value of the rate constant calculated from the three data sets? (d) What is the rate of disappearance of NO when $[\text{NO}] = 0.0750\text{ M}$ and $[\text{O}_2] = 0.0100\text{ M}$? (e) What is the rate of disappearance of O_2 at the concentrations given in part (d)?

[14.37] Consider the gas-phase reaction between nitric oxide and bromine at 273°C : $2\text{NO}(g) + \text{Br}_2(g) \longrightarrow 2\text{NOBr}(g)$. The following data for the initial rate of appearance of NOBr were obtained:

Experiment	$[\text{NO}] (\text{M})$	$[\text{Br}_2] (\text{M})$	Initial Rate (M/s)
1	0.10	0.20	24
2	0.25	0.20	150
3	0.10	0.50	60
4	0.35	0.50	735

(a) Determine the rate law. (b) Calculate the average value of the rate constant for the appearance of NOBr from the four data sets. (c) How is the rate of appearance of NOBr related to the rate of disappearance of Br_2 ? (d) What is the rate of disappearance of Br_2 when $[\text{NO}] = 0.075\text{ M}$ and $[\text{Br}_2] = 0.25\text{ M}$?

[14.38] Consider the reaction of peroxydisulfate ion ($\text{S}_2\text{O}_8^{2-}$) with iodide ion (I^-) in aqueous solution:

At a particular temperature the initial rate of disappearance of $\text{S}_2\text{O}_8^{2-}$ varies with reactant concentrations in the following manner:

Experiment	$[\text{S}_2\text{O}_8^{2-}] (\text{M})$	$[\text{I}^-] (\text{M})$	Initial Rate (M/s)
1	0.018	0.036	2.6×10^{-6}
2	0.027	0.036	3.9×10^{-6}
3	0.036	0.054	7.8×10^{-6}
4	0.050	0.072	1.4×10^{-5}

(a) Determine the rate law for the reaction and state the units of the rate constant. (b) What is the average value of the rate constant for the disappearance of $\text{S}_2\text{O}_8^{2-}$ based on the four sets of data? (c) How is the rate of disappearance of $\text{S}_2\text{O}_8^{2-}$ related to the rate of disappearance of I^- ? (d) What is the rate of disappearance of I^- when $[\text{S}_2\text{O}_8^{2-}] = 0.025\text{ M}$ and $[\text{I}^-] = 0.050\text{ M}$?

CHANGE OF CONCENTRATION WITH TIME (section 14.4)

14.39 (a) Define the following symbols that are encountered in rate equations for the generic reaction $A \longrightarrow B$: $[A]_0$, $t_{1/2}$, $[A]_t$, k . (b) What quantity, when graphed versus time, will yield a straight line for a first-order reaction? (c) How can you calculate the rate constant for a first-order reaction from the graph you made in part (b)?

14.40 (a) For a generic second-order reaction $A \longrightarrow B$, what quantity, when graphed versus time, will yield a straight line? (b) What is the slope of the straight line from part (a)? (c) How do the half-lives of first-order and second-order reactions differ?

14.41 For the generic reaction $A \longrightarrow B$ that is zero order in A, what would you graph in order to obtain the rate constant?

14.42 Sketch a graph for the generic first-order reaction $A \longrightarrow B$ that has concentration of A on the vertical axis and time on the horizontal axis. (a) Is this graph linear? Explain. (b) Indicate on your graph the half-life for the reaction.

14.43 (a) The gas-phase decomposition of SO_2Cl_2 , $\text{SO}_2\text{Cl}_2(\text{g}) \longrightarrow \text{SO}_2(\text{g}) + \text{Cl}_2(\text{g})$, is first order in SO_2Cl_2 . At 600 K the half-life for this process is 2.3×10^5 s. What is the rate constant at this temperature? (b) At 320 °C the rate constant is $2.2 \times 10^{-5} \text{ s}^{-1}$. What is the half-life at this temperature?

14.44 Molecular iodine, $\text{I}_2(\text{g})$, dissociates into iodine atoms at 625 K with a first-order rate constant of 0.271 s^{-1} . (a) What is the half-life for this reaction? (b) If you start with 0.050 M I_2 at this temperature, how much will remain after 5.12 s assuming that the iodine atoms do not recombine to form I_2 ?

14.45 As described in Exercise 14.43, the decomposition of sulfuric chloride (SO_2Cl_2) is a first-order process. The rate constant for the decomposition at 660 K is $4.5 \times 10^{-2} \text{ s}^{-1}$. (a) If we begin with an initial SO_2Cl_2 pressure of 450 torr, what is the pressure of this substance after 60 s? (b) At what time will the pressure of SO_2Cl_2 decline to one-tenth its initial value?

14.46 The first-order rate constant for the decomposition of N_2O_5 , $2 \text{N}_2\text{O}_5(\text{g}) \longrightarrow 4 \text{NO}_2(\text{g}) + \text{O}_2(\text{g})$, at 70 °C is $6.82 \times 10^{-3} \text{ s}^{-1}$. Suppose we start with 0.0250 mol of $\text{N}_2\text{O}_5(\text{g})$ in a volume of 2.0 L. (a) How many moles of N_2O_5 will remain after 5.0 min? (b) How many minutes will it take for the quantity of N_2O_5 to drop to 0.010 mol? (c) What is the half-life of N_2O_5 at 70 °C?

14.47 The reaction

is first order in SO_2Cl_2 . Using the following kinetic data, determine the magnitude and units of the first-order rate constant:

Time (s)	Pressure SO_2Cl_2 (atm)
0	1.000
2,500	0.947
5,000	0.895
7,500	0.848
10,000	0.803

14.48 From the following data for the first-order gas-phase isomerization of CH_3NC at 215 °C, calculate the first-order rate constant and half-life for the reaction:

Time (s)	Pressure CH_3NC (torr)
0	502
2,000	335
5,000	180
8,000	95.5
12,000	41.7
15,000	22.4

14.49 Consider the data presented in Exercise 14.19. (a) By using appropriate graphs, determine whether the reaction is first order or second order. (b) What is the rate constant for the reaction? (c) What is the half-life for the reaction?

14.50 Consider the data presented in Exercise 14.20. (a) Determine whether the reaction is first order or second order. (b) What is the rate constant? (c) What is the half-life?

14.51 The gas-phase decomposition of NO_2 , $2 \text{NO}_2(\text{g}) \longrightarrow 2 \text{NO}(\text{g}) + \text{O}_2(\text{g})$, is studied at 383 °C, giving the following data:

Time (s)	$[\text{NO}_2]$ (M)
0.0	0.100
5.0	0.017
10.0	0.0090
15.0	0.0062
20.0	0.0047

(a) Is the reaction first order or second order with respect to the concentration of NO_2 ? (b) What is the rate constant? (c) If you used the method of initial rates to obtain the order for NO_2 , predict what reaction rates you would measure in the beginning of the reaction for initial concentrations of 0.200 M, 0.100 M, and 0.050 M NO_2 .

14.52 Sucrose ($\text{C}_{12}\text{H}_{22}\text{O}_{11}$), commonly known as table sugar, reacts in dilute acid solutions to form two simpler sugars, glucose and fructose, both of which have the formula $\text{C}_6\text{H}_{12}\text{O}_6$. At 23 °C and in 0.5 M HCl, the following data were obtained for the disappearance of sucrose:

Time (min)	$[\text{C}_{12}\text{H}_{22}\text{O}_{11}]$ (M)
0	0.316
39	0.274
80	0.238
140	0.190
210	0.146

(a) Is the reaction first order or second order with respect to $[\text{C}_{12}\text{H}_{22}\text{O}_{11}]$? (b) What is the rate constant? (c) Using this rate constant, calculate the concentration of sucrose at 39, 80, 140, and 210 min if the initial sucrose concentration was 0.316 M and the reaction was zero order in sucrose.

TEMPERATURE AND RATE (section 14.5)

- 14.53** (a) What factors determine whether a collision between two molecules will lead to a chemical reaction? (b) According to the collision model, why does temperature affect the value of the rate constant? (c) Does the rate constant for a reaction generally increase or decrease with an increase in reaction temperature?
- 14.54** (a) In which of the following reactions would you expect the orientation factor to be least important in leading to reaction: $\text{NO} + \text{O} \longrightarrow \text{NO}_2$ or $\text{H} + \text{Cl} \longrightarrow \text{HCl}$? (b) How does the kinetic-molecular theory help us understand the temperature dependence of chemical reactions?
- 14.55** Calculate the fraction of atoms in a sample of argon gas at 400 K that has an energy of 10.0 kJ or greater.
- 14.56** (a) The activation energy for the isomerization of methyl isonitrile (Figure 14.7) is 160 kJ/mol. Calculate the fraction of methyl isonitrile molecules that has an energy of 160.0 kJ or greater at 500 K. (b) Calculate this fraction for a temperature of 520 K. What is the ratio of the fraction at 520 K to that at 500 K?
- 14.57** The gas-phase reaction $\text{Cl}(g) + \text{HBr}(g) \longrightarrow \text{HCl}(g) + \text{Br}(g)$ has an overall enthalpy change of -66 kJ. The activation energy for the reaction is 7 kJ. (a) Sketch the energy profile for the reaction, and label E_a and ΔE . (b) What is the activation energy for the reverse reaction?
- 14.58** For the elementary process $\text{N}_2\text{O}_5(g) \longrightarrow \text{NO}_2(g) + \text{NO}_3(g)$ the activation energy (E_a) and overall ΔE are 154 kJ/mol and 136 kJ/mol, respectively. (a) Sketch the energy profile for this reaction, and label E_a and ΔE . (b) What is the activation energy for the reverse reaction?
- 14.59** Indicate whether each statement is true or false. If it is false, rewrite it so that it is true.
- If you compare two reactions with similar collision factors, the one with the larger activation energy will be faster.
 - A reaction that has a small rate constant must have a small frequency factor.
 - Increasing the reaction temperature increases the fraction of successful collisions between reactants.
- 14.60** Indicate whether each statement is true or false. If it is false, rewrite it so that it is true.
- If you measure the rate constant for a reaction at different temperatures, you can calculate the overall enthalpy change for the reaction.
 - Exothermic reactions are faster than endothermic reactions.
 - If you double the temperature for a reaction, you cut the activation energy in half.
- 14.61** Based on their activation energies and energy changes and assuming that all collision factors are the same, which of the following reactions would be fastest and which would be slowest? Explain your answer.
- $E_a = 45$ kJ/mol; $\Delta E = -25$ kJ/mol
 - $E_a = 35$ kJ/mol; $\Delta E = -10$ kJ/mol
 - $E_a = 55$ kJ/mol; $\Delta E = 10$ kJ/mol
- 14.62** Which of the reactions in Exercise 14.61 will be fastest in the reverse direction? Which will be slowest? Explain.
- 14.63** (a) A certain first-order reaction has a rate constant of $2.75 \times 10^{-2} \text{ s}^{-1}$ at 20 °C. What is the value of k at 60 °C if $E_a = 75.5$ kJ/mol? (b) Another first-order reaction also has a rate constant of $2.75 \times 10^{-2} \text{ s}^{-1}$ at 20 °C. What is the value of k at 60 °C if $E_a = 125$ kJ/mol? (c) What assumptions do you need to make in order to calculate answers for parts (a) and (b)?
- 14.64** Understanding the high-temperature behavior of nitrogen oxides is essential for controlling pollution generated in automobile engines. The decomposition of nitric oxide (NO) to N_2 and O_2 is second order with a rate constant of $0.0796 \text{ M}^{-1} \text{ s}^{-1}$ at 737 °C and $0.0815 \text{ M}^{-1} \text{ s}^{-1}$ at 947 °C. Calculate the activation energy for the reaction.
- 14.65** The rate of the reaction
- $$\text{CH}_3\text{COOC}_2\text{H}_5(aq) + \text{OH}^-(aq) \longrightarrow \text{CH}_3\text{COO}^-(aq) + \text{C}_2\text{H}_5\text{OH}(aq)$$
- was measured at several temperatures, and the following data were collected:
- | Temperature (°C) | k ($\text{M}^{-1} \text{ s}^{-1}$) |
|------------------|--|
| 15 | 0.0521 |
| 25 | 0.101 |
| 35 | 0.184 |
| 45 | 0.332 |
- Calculate the value of E_a by constructing an appropriate graph.
- 14.66** The temperature dependence of the rate constant for a reaction is tabulated as follows:
- | Temperature (K) | k ($\text{M}^{-1} \text{ s}^{-1}$) |
|-----------------|--|
| 600 | 0.028 |
| 650 | 0.22 |
| 700 | 1.3 |
| 750 | 6.0 |
| 800 | 23 |
- Calculate E_a and A .
- [14.67]** The activation energy of a certain reaction is 65.7 kJ/mol. How many times faster will the reaction occur at 50 °C than at 0 °C? State the assumptions you need to make in order to perform this calculation.
- [14.68]** The following is a quote from an article in the August 18, 1998, issue of *The New York Times* about the breakdown of cellulose and starch: "A drop of 18 degrees Fahrenheit [from 77 °F to 59 °F] lowers the reaction rate six times; a 36-degree drop [from 77 °F to 41 °F] produces a fortyfold decrease in the rate." (a) Calculate activation energies for the breakdown process based on the two estimates of the effect of temperature on rate. Are the values consistent? (b) Assuming the value of E_a calculated from the 36-degree drop and that the rate of breakdown is first order with a half-life at 25 °C of 2.7 years, calculate the half-life for breakdown at a temperature of -15 °C.

REACTION MECHANISMS (section 14.6)

14.69 (a) What is meant by the term *elementary reaction*? (b) What is the difference between a *unimolecular* and a *bimolecular elementary reaction*? (c) What is a *reaction mechanism*?

14.70 (a) What is meant by the term *molecularity*? (b) Why are termolecular elementary reactions so rare? (c) What is an *intermediate* in a mechanism?

14.71 What are the differences between an intermediate and a transition state?

14.72 What is meant by the term *rate-determining step*?

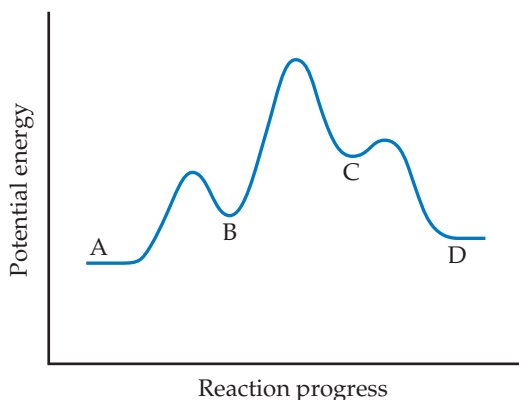

14.73 What is the molecularity of each of the following elementary reactions? Write the rate law for each.

14.74 What is the molecularity of each of the following elementary reactions? Write the rate law for each.

14.75 (a) Based on the following reaction profile, how many intermediates are formed in the reaction $\text{A} \longrightarrow \text{D}$? (b) How many transition states are there? (c) Which step is the fastest? (d) Is the reaction $\text{A} \longrightarrow \text{D}$ exothermic or endothermic?

14.76 Consider the following energy profile.

(a) How many elementary reactions are in the reaction mechanism? (b) How many intermediates are formed in the reaction? (c) Which step is rate limiting? (d) Is the overall reaction exothermic or endothermic?

14.77 The following mechanism has been proposed for the gas-phase reaction of H_2 with ICl :

(a) Write the balanced equation for the overall reaction. (b) Identify any intermediates in the mechanism. (c) If the first step is slow and the second one is fast, which rate law do you expect to be observed for the overall reaction?

14.78 The decomposition of hydrogen peroxide is catalyzed by iodide ion. The catalyzed reaction is thought to proceed by a two-step mechanism:

(a) Write the chemical equation for the overall process. (b) Identify the intermediate, if any, in the mechanism. (c) Assuming that the first step of the mechanism is rate determining, predict the rate law for the overall process.

14.79 The reaction $2 \text{NO}(\text{g}) + \text{Cl}_2(\text{g}) \longrightarrow 2 \text{NOCl}(\text{g})$ was performed and the following data obtained:

Is the following mechanism consistent with the data? Explain.

14.80 You have studied the gas-phase oxidation of HBr by O_2 :

You find the reaction to be first order with respect to HBr and first order with respect to O_2 . You propose the following mechanism:

(a) Confirm that the elementary reactions add to give the overall reaction. (b) Based on the experimentally determined rate law, which step is rate determining? (c) What are the intermediates in this mechanism? (d) If you are unable to detect HOBr or HOBr among the products, does this disprove your mechanism?

CATALYSIS (section 14.7)

- 14.81** (a) What is a catalyst? (b) What is the difference between a homogeneous and a heterogeneous catalyst? (c) Do catalysts affect the overall enthalpy change for a reaction, the activation energy, or both?
- 14.82** (a) Most commercial heterogeneous catalysts are extremely finely divided solid materials. Why is particle size important? (b) What role does adsorption play in the action of a heterogeneous catalyst?
-
- [14.83]** Platinum nanoparticles of diameter ~ 2 nm are important catalysts in carbon monoxide oxidation to carbon dioxide. Platinum crystallizes in a face-centered cubic arrangement with an edge length of 3.924 Å. (a) Estimate how many platinum atoms would fit into a 2.0-nm sphere; the volume of a sphere is $(4/3)\pi r^3$. Recall that $1\text{Å} = 1 \times 10^{-10}$ m and $1\text{ nm} = 1 \times 10^{-9}$ m. (b) Estimate how many platinum atoms are on the surface of a 2.0-nm Pt sphere, using the surface area of a sphere ($4\pi r^2$) and assuming that the “footprint” of one Pt atom can be estimated from its atomic diameter of 2.8 Å. (c) Using your results from (a) and (b), calculate the percentage of Pt atoms that are on the surface of a 2.0-nm nanoparticle. (d) Repeat these calculations for a 5.0-nm platinum nanoparticle. (e) Which size of nanoparticle would you expect to be more catalytically active and why?
- 14.84** In solution, chemical species as simple as H^+ and OH^- can serve as catalysts for reactions. Imagine you could measure the $[\text{H}^+]$ of a solution containing an acid-catalyzed reaction as it occurs. Assume the reactants and products themselves are neither acids nor bases. Sketch the $[\text{H}^+]$ concentration profile you would measure as a function of time for the reaction, assuming $t = 0$ is when you add a drop of acid to the reaction.
-
- 14.85** The oxidation of SO_2 to SO_3 is catalyzed by NO_2 . The reaction proceeds according to:
- $$\text{NO}_2(\text{g}) + \text{SO}_2(\text{g}) \longrightarrow \text{NO}(\text{g}) + \text{SO}_3(\text{g})$$
- $$2\text{NO}(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 2\text{NO}_2(\text{g})$$
- (a) Show that the two reactions can be summed to give the overall oxidation of SO_2 by O_2 to give SO_3 . (b) Why do we consider NO_2 a catalyst and not an intermediate in this reaction? (c) Is this an example of homogeneous catalysis or heterogeneous catalysis?
- 14.86** NO catalyzes the decomposition of N_2O , possibly by the following mechanism:
- $$\text{NO}(\text{g}) + \text{N}_2\text{O}(\text{g}) \longrightarrow \text{N}_2(\text{g}) + \text{NO}_2(\text{g})$$
- $$2\text{NO}_2(\text{g}) \longrightarrow 2\text{NO}(\text{g}) + \text{O}_2(\text{g})$$
- (a) What is the chemical equation for the overall reaction? Show how the two steps can be added to give the overall equation. (b) Why is NO considered a catalyst and not an intermediate? (c) If experiments show that during the decomposition of N_2O , NO_2 does not accumulate in measurable quantities, does this rule out the proposed mechanism? If you think not, suggest what might be going on.
-
- 14.87** Many metallic catalysts, particularly the precious-metal ones, are often deposited as very thin films on a substance of high surface area per unit mass, such as alumina (Al_2O_3) or silica (SiO_2). (a) Why is this an effective way of utilizing the catalyst material compared to having powdered metals? (b) How does the surface area affect the rate of reaction?
- 14.88** (a) If you were going to build a system to check the effectiveness of automobile catalytic converters on cars, what substances would you want to look for in the car exhaust? (b) Automobile catalytic converters have to work at high temperatures, as hot exhaust gases stream through them. In what ways could this be an advantage? In what ways a disadvantage? (c) Why is the rate of flow of exhaust gases over a catalytic converter important?
-
- 14.89** When D_2 reacts with ethylene (C_2H_4) in the presence of a finely divided catalyst, ethane with two deuteriums, $\text{CH}_2\text{D}-\text{CH}_2\text{D}$, is formed. (Deuterium, D, is an isotope of hydrogen of mass 2). Very little ethane forms in which two deuteriums are bound to one carbon (for example, CH_3-CHD_2). Use the sequence of steps involved in the reaction (Figure 14.24) to explain why this is so.
- 14.90** Heterogeneous catalysts that perform hydrogenation reactions, as illustrated in Figure 14.24, are subject to “poisoning,” which shuts down their catalytic ability. Compounds of sulfur are often poisons. Suggest a mechanism by which such compounds might act as poisons.
-
- 14.91** (a) Explain the importance of enzymes in biological systems. (b) What chemical transformations are catalyzed (i) by the enzyme catalase, (ii) by nitrogenase? (c) Many enzymes follow this generic reaction mechanism, where E is enzyme, S is substrate, ES is the enzyme-substrate complex (where the substrate is bound to the enzyme’s active site), and P is the product:
- $\text{E} + \text{S} \rightleftharpoons \text{ES}$
 - $\text{ES} \longrightarrow \text{E} + \text{P}$
- What assumptions are made in this model with regard to the rate of the bound substrate being chemically transformed into bound product in the active site?
- 14.92** There are literally thousands of enzymes at work in complex living systems such as human beings. What properties of enzymes give rise to their ability to distinguish one substrate from another?
-
- 14.93** The enzyme carbonic anhydrase catalyzes the reaction $\text{CO}_2(\text{g}) + \text{H}_2\text{O}(\text{l}) \longrightarrow \text{HCO}_3^-(\text{aq}) + \text{H}^+(\text{aq})$. In water, without the enzyme, the reaction proceeds with a rate constant of 0.039 s^{-1} at 25°C . In the presence of the enzyme in water, the reaction proceeds with a rate constant of $1.0 \times 10^6\text{ s}^{-1}$ at 25°C . Assuming the collision factor is the same for both situations, calculate the difference in activation energies for the uncatalyzed versus enzyme-catalyzed reaction.
- 14.94** The enzyme urease catalyzes the reaction of urea, $(\text{NH}_2\text{CONH}_2)$, with water to produce carbon dioxide and ammonia. In water, without the enzyme, the reaction proceeds with a first-order rate constant of $4.15 \times 10^{-5}\text{ s}^{-1}$ at 100°C . In the presence of the enzyme in water, the reaction proceeds with a rate constant of $3.4 \times 10^4\text{ s}^{-1}$ at 21°C . (a) Write out the balanced equation for the reaction catalyzed by urease. (b) Assuming the collision factor is the same for both situations, estimate the difference in activation energies for the uncatalyzed versus enzyme-catalyzed reaction.
-
- [14.95]** The activation energy of an uncatalyzed reaction is 95 kJ/mol. The addition of a catalyst lowers the activation energy to 55 kJ/mol. Assuming that the collision factor remains the same, by what factor will the catalyst increase the rate of the reaction at (a) 25°C , (b) 125°C ?

[14.96] Suppose that a certain biologically important reaction is quite slow at physiological temperature (37 °C) in the absence of a catalyst. Assuming that the collision factor remains the same,

by how much must an enzyme lower the activation energy of the reaction in order to achieve a 1×10^5 -fold increase in the reaction rate?

ADDITIONAL EXERCISES

14.97 Explain why rate laws generally cannot be written from balanced equations. Under what circumstance is the rate law related directly to the balanced equation for a reaction?

14.98 Hydrogen sulfide (H_2S) is a common and troublesome pollutant in industrial wastewaters. One way to remove H_2S is to treat the water with chlorine, in which case the following reaction occurs:

The rate of this reaction is first order in each reactant. The rate constant for the disappearance of H_2S at 28 °C is $3.5 \times 10^{-2} \text{ M}^{-1} \text{ s}^{-1}$. If at a given time the concentration of H_2S is $2.0 \times 10^{-4} \text{ M}$ and that of Cl_2 is 0.025 M, what is the rate of formation of Cl^- ?

14.99 The reaction $2\text{NO}(g) + \text{O}_2(g) \longrightarrow 2\text{NO}_2(g)$ is second order in NO and first order in O_2 . When $[\text{NO}] = 0.040 \text{ M}$ and $[\text{O}_2] = 0.035 \text{ M}$, the observed rate of disappearance of NO is $9.3 \times 10^{-5} \text{ M/s}$. (a) What is the rate of disappearance of O_2 at this moment? (b) What is the value of the rate constant? (c) What are the units of the rate constant? (d) What would happen to the rate if the concentration of NO were increased by a factor of 1.8?

14.100 Consider the following reaction between mercury(II) chloride and oxalate ion:

The initial rate of this reaction was determined for several concentrations of HgCl_2 and $\text{C}_2\text{O}_4^{2-}$, and the following rate data were obtained for the rate of disappearance of $\text{C}_2\text{O}_4^{2-}$:

Experiment	$[\text{HgCl}_2] \text{ (M)}$	$[\text{C}_2\text{O}_4^{2-}] \text{ (M)}$	Rate (M/s)
1	0.164	0.15	3.2×10^{-5}
2	0.164	0.45	2.9×10^{-4}
3	0.082	0.45	1.4×10^{-4}
4	0.246	0.15	4.8×10^{-5}

(a) What is the rate law for this reaction? (b) What is the value of the rate constant with proper units? (c) What is the reaction rate when the initial concentration of HgCl_2 is 0.100 M and that of ($\text{C}_2\text{O}_4^{2-}$) is 0.25 M if the temperature is the same as that used to obtain the data shown?

14.101 The reaction $2\text{NO}_2 \longrightarrow 2\text{NO} + \text{O}_2$ has the rate constant $k = 0.63 \text{ M}^{-1} \text{ s}^{-1}$. Based on the units for k , is the reaction first or second order in NO_2 ? If the initial concentration of NO_2 is 0.100 M, how would you determine how long it would take for the concentration to decrease to 0.025 M?

14.102 Consider two reactions. Reaction (1) has a constant half-life, whereas reaction (2) has a half-life that gets longer as the reaction proceeds. What can you conclude about the rate laws of these reactions from these observations?

[14.103] When chemists are performing kinetics experiments, the general rule of thumb is to allow the reaction to proceed for 4 half-lives. (a) Explain how you would be able to tell that the reaction has proceeded for 4 half-lives. (b) Let us suppose a reaction $\text{A} \rightarrow \text{B}$ takes 6 days to proceed for 4 half-lives and is first order in A. However, when your lab partner performs this reaction for the first time, he does not realize how long it takes, and he stops taking kinetic data, monitoring the loss of A, after only 2 hours. Your lab partner concludes the reaction is zero order in A based on the data. Sketch a graph of [A] versus time to convince your lab partner the two of you need to be in the lab for a few days to obtain the proper rate law for the reaction.

14.104 (a) The reaction $\text{H}_2\text{O}_2(aq) \longrightarrow \text{H}_2\text{O}(l) + \frac{1}{2}\text{O}_2(g)$ is first order. Near room temperature, the rate constant equals $7.0 \times 10^{-4} \text{ s}^{-1}$. Calculate the half-life at this temperature. (b) At 415 °C, $(\text{CH}_2)_2\text{O}$ decomposes in the gas phase, $(\text{CH}_2)_2\text{O}(g) \longrightarrow \text{CH}_4(g) + \text{CO}(g)$. If the reaction is first order with a half-life of 56.3 min at this temperature, calculate the rate constant in s^{-1} .

14.105 Americium-241 is used in smoke detectors. It has a first order rate constant for radioactive decay of $k = 1.6 \times 10^{-3} \text{ yr}^{-1}$. By contrast, iodine-125, which is used to test for thyroid functioning, has a rate constant for radioactive decay of $k = 0.011 \text{ day}^{-1}$. (a) What are the half-lives of these two isotopes? (b) Which one decays at a faster rate? (c) How much of a 1.00-mg sample of each isotope remains after 3 half-lives? (d) How much of a 1.00-mg sample of each isotope remains after 4 days?

14.106 Urea (NH_2CONH_2) is the end product in protein metabolism in animals. The decomposition of urea in 0.1 M HCl occurs according to the reaction

The reaction is first order in urea and first order overall. When $[\text{NH}_2\text{CONH}_2] = 0.200 \text{ M}$, the rate at 61.05 °C is $8.56 \times 10^{-5} \text{ M/s}$. (a) What is the rate constant, k ? (b) What is the concentration of urea in this solution after $4.00 \times 10^3 \text{ s}$ if the starting concentration is 0.500 M? (c) What is the half-life for this reaction at 61.05 °C?

14.107 The rate of a first-order reaction is followed by spectroscopy, monitoring the absorbance of a colored reactant at 520 nm. The reaction occurs in a 1.00-cm sample cell, and the only colored species in the reaction has an extinction coefficient of $5.60 \times 10^3 \text{ M}^{-1} \text{ cm}^{-1}$ at 520 nm. (a) Calculate the initial concentration of the colored reactant if the absorbance is 0.605 at the beginning of the reaction. (b) The absorbance falls to 0.250 at 30.0 min. Calculate the rate constant in units of s^{-1} . (c) Calculate the half-life of the reaction. (d) How long does it take for the absorbance to fall to 0.100?

- [14.108] A colored dye compound decomposes to give a colorless product. The original dye absorbs at 608 nm and has an extinction coefficient of $4.7 \times 10^4 \text{ M}^{-1}\text{cm}^{-1}$ at that wavelength. You perform the decomposition reaction in a 1-cm cuvette in a spectrometer and obtain the following data:

Time (min)	Absorbance at 608 nm
0	1.254
30	0.941
60	0.752
90	0.672
120	0.545

From these data, determine the rate law for the reaction "dye \longrightarrow product" and determine the rate constant.

- 14.109 Cyclopentadiene (C_5H_6) reacts with itself to form dicyclopentadiene ($\text{C}_{10}\text{H}_{12}$). A 0.0400 M solution of C_5H_6 was monitored as a function of time as the reaction $2 \text{C}_5\text{H}_6 \longrightarrow \text{C}_{10}\text{H}_{12}$ proceeded. The following data were collected:

Time (s)	$[\text{C}_5\text{H}_6]$ (M)
0.0	0.0400
50.0	0.0300
100.0	0.0240
150.0	0.0200
200.0	0.0174

Plot $[\text{C}_5\text{H}_6]$ versus time, $\ln [\text{C}_5\text{H}_6]$ versus time, and $1/[\text{C}_5\text{H}_6]$ versus time. What is the order of the reaction? What is the value of the rate constant?

- 14.110 (a) Two reactions have identical values for E_a . Does this ensure that they will have the same rate constant if run at the same temperature? Explain. (b) Two similar reactions have the same rate constant at 25 °C, but at 35 °C one of the reactions has a larger rate constant than the other. Account for these observations.
- 14.111 The first-order rate constant for reaction of a particular organic compound with water varies with temperature as follows:

Temperature (K)	Rate Constant (s^{-1})
300	3.2×10^{-11}
320	1.0×10^{-9}
340	3.0×10^{-8}
355	2.4×10^{-7}

From these data, calculate the activation energy in units of kJ/mol.

- 14.112 The following mechanism has been proposed for the reaction of NO with H_2 to form N_2O and H_2O :

(a) Show that the elementary reactions of the proposed mechanism add to provide a balanced equation for the reaction. (b) Write a rate law for each elementary reaction in the mechanism. (c) Identify any intermediates in the mechanism. (d) The observed rate law is $\text{rate} = k[\text{NO}]^2[\text{H}_2]$. If the proposed mechanism is correct, what can we conclude about the relative speeds of the first and second reactions?

- 14.113 Ozone in the upper atmosphere can be destroyed by the following two-step mechanism:

(a) What is the overall equation for this process? (b) What is the catalyst in the reaction? How do you know? (c) What is the intermediate in the reaction? How do you distinguish it from the catalyst?

- 14.114 Using Figure 14.23 as your basis, draw the energy profile for the bromide-catalyzed decomposition of hydrogen peroxide. (a) Label the curve with the activation energies for reactions [14.30] and [14.31]. (b) Notice from Figure 14.22 that when $\text{Br}^-(aq)$ is first added, Br_2 accumulates to some extent during the reaction and the solution turns brown. What does this tell us about the relative rates of the reactions represented by Equations 14.30 and 14.31?

- [14.115] The following mechanism has been proposed for the gas-phase reaction of chloroform (CHCl_3) and chlorine:

(a) What is the overall reaction? (b) What are the intermediates in the mechanism? (c) What is the molecularity of each of the elementary reactions? (d) What is the rate-determining step? (e) What is the rate law predicted by this mechanism? (Hint: The overall reaction order is not an integer.)

- [14.116] In a hydrocarbon solution, the gold compound $(\text{CH}_3)_3\text{AuPH}_3$ decomposes into ethane (C_2H_6) and a different gold compound, $(\text{CH}_3)\text{AuPH}_3$. The following mechanism has been proposed for the decomposition of $(\text{CH}_3)_3\text{AuPH}_3$:

(a) What is the overall reaction? (b) What are the intermediates in the mechanism? (c) What is the molecularity of each of the elementary steps? (d) What is the rate-determining step? (e) What is the rate law predicted by this mechanism? (f) What would be the effect on the reaction rate of adding PH_3 to the solution of $(\text{CH}_3)_3\text{AuPH}_3$?

- 14.117 One of the many remarkable enzymes in the human body is carbonic anhydrase, which catalyzes the interconversion of carbon dioxide and water with bicarbonate ion and protons. If it were not for this enzyme, the body could not rid itself

rapidly enough of the CO_2 accumulated by cell metabolism. The enzyme catalyzes the dehydration (release to air) of up to 10^7 CO_2 molecules per second. Which components of this description correspond to the terms *enzyme*, *substrate*, and *turnover number*?

- 14.118** Enzymes are often described as following the two-step mechanism:

where E = enzyme, S = substrate, ES = enzyme-substrate complex, and P = product.

INTEGRATIVE EXERCISES

- 14.119** Dinitrogen pentoxide (N_2O_5) decomposes in chloroform as a solvent to yield NO_2 and O_2 . The decomposition is first order with a rate constant at 45°C of $1.0 \times 10^{-5} \text{ s}^{-1}$. Calculate the partial pressure of O_2 produced from 1.00 L of 0.600 M N_2O_5 solution at 45°C over a period of 20.0 hr if the gas is collected in a 10.0-L container. (Assume that the products do not dissolve in chloroform.)

- [14.120]** The reaction between ethyl iodide and hydroxide ion in ethanol ($\text{C}_2\text{H}_5\text{OH}$) solution, $\text{C}_2\text{H}_5\text{I}(\text{alc}) + \text{OH}^-(\text{alc}) \longrightarrow \text{C}_2\text{H}_5\text{OH}(\text{l}) + \text{I}^-(\text{alc})$, has an activation energy of 86.8 kJ/mol and a frequency factor of $2.10 \times 10^{11} \text{ M}^{-1} \text{ s}^{-1}$. (a) Predict the rate constant for the reaction at 35°C . (b) A solution of KOH in ethanol is made up by dissolving 0.335 g KOH in ethanol to form 250.0 mL of solution. Similarly, 1.453 g of $\text{C}_2\text{H}_5\text{I}$ is dissolved in ethanol to form 250.0 mL of solution. Equal volumes of the two solutions are mixed. Assuming the reaction is first order in each reactant, what is the initial rate at 35°C ? (c) Which reagent in the reaction is limiting, assuming the reaction proceeds to completion? (d) Assuming the frequency factor and activation energy do not change as a function of temperature, calculate the rate constant for the reaction at 50°C .

- [14.121]** You obtain kinetic data for a reaction at a set of different temperatures. You plot $\ln k$ versus $1/T$ and obtain the following graph:

Suggest a molecular-level interpretation of these unusual data.

- (a) If an enzyme follows this mechanism, what rate law is expected for the reaction? (b) Molecules that can bind to the active site of an enzyme but are not converted into product are called *enzyme inhibitors*. Write an additional elementary step to add into the preceding mechanism to account for the reaction of E with I, an inhibitor.

- 14.122** The gas-phase reaction of NO with F_2 to form NOF and F has an activation energy of $E_a = 6.3 \text{ kJ/mol}$ and a frequency factor of $A = 6.0 \times 10^8 \text{ M}^{-1} \text{ s}^{-1}$. The reaction is believed to be bimolecular:

- (a) Calculate the rate constant at 100°C . (b) Draw the Lewis structures for the NO and the NOF molecules, given that the chemical formula for NOF is misleading because the nitrogen atom is actually the central atom in the molecule. (c) Predict the shape for the NOF molecule. (d) Draw a possible transition state for the formation of NOF, using dashed lines to indicate the weak bonds that are beginning to form. (e) Suggest a reason for the low activation energy for the reaction.

- 14.123** The mechanism for the oxidation of HBr by O_2 to form 2 H_2O and Br_2 is shown in Exercise 14.80. (a) Calculate the overall standard enthalpy change for the reaction process. (b) HBr does not react with O_2 at a measurable rate at room temperature under ordinary conditions. What can you infer from this about the magnitude of the activation energy for the rate-determining step? (c) Draw a plausible Lewis structure for the intermediate HOObBr. To what familiar compound of hydrogen and oxygen does it appear similar?

- [14.124]** The rates of many atmospheric reactions are accelerated by the absorption of light by one of the reactants. For example, consider the reaction between methane and chlorine to produce methyl chloride and hydrogen chloride:

This reaction is very slow in the absence of light. However, $\text{Cl}_2(\text{g})$ can absorb light to form Cl atoms:

Once the Cl atoms are generated, they can catalyze the reaction of CH_4 and Cl_2 , according to the following proposed mechanism:

The enthalpy changes and activation energies for these two reactions are tabulated as follows:

Reaction	ΔH° (kJ/mol)	E_a (kJ/mol)
3	+4	17
4	-109	4

(a) By using the bond enthalpy for Cl_2 (Table 8.4), determine the longest wavelength of light that is energetic enough to cause reaction 2 to occur. In which portion of the electromagnetic spectrum is this light found? (b) By using the data tabulated here, sketch a quantitative energy profile for the catalyzed reaction represented by reactions 3 and 4. (c) By using bond enthalpies, estimate where the reactants, $\text{CH}_4(g) + \text{Cl}_2(g)$, should be placed on your diagram in part (b). Use this result to estimate the value of E_a for the reaction $\text{CH}_4(g) + \text{Cl}_2(g) \longrightarrow \text{CH}_3(g) + \text{HCl}(g) + \text{Cl}(g)$. (d) The species $\text{Cl}(g)$ and $\text{CH}_3(g)$ in reactions 3 and 4 are radicals, that is, atoms or molecules with unpaired electrons. Draw a Lewis structure of CH_3 , and verify that it is a radical. (e) The

sequence of reactions 3 and 4 comprises a radical chain mechanism. Why do you think this is called a “chain reaction”? Propose a reaction that will terminate the chain reaction.

- [14.125] Many primary amines, RNH_2 , where R is a carbon-containing fragment such as CH_3 , CH_3CH_2 , and so on, undergo reactions where the transition state is tetrahedral. (a) Draw a hybrid orbital picture to visualize the bonding at the nitrogen in a primary amine (just use a C atom for “R”). (b) What kind of reactant with a primary amine can produce a tetrahedral intermediate?
- [14.126] The NO_x waste stream from automobile exhaust includes species such as NO and NO_2 . Catalysts that convert these species to N_2 are desirable to reduce air pollution. (a) Draw the Lewis dot and VSEPR structures of NO, NO_2 , and N_2 . (b) Using a resource such as Table 8.4, look up the energies of the bonds in these molecules. In what region of the electromagnetic spectrum are these energies? (c) Design a spectroscopic experiment to monitor the conversion of NO_x into N_2 , describing what wavelengths of light need to be monitored as a function of time.

WHAT'S AHEAD

15.1 THE CONCEPT OF EQUILIBRIUM

We begin by examining reversible reactions and the concept of equilibrium.

15.2 THE EQUILIBRIUM CONSTANT

We define the *equilibrium constant* based on rates of forward and reverse reactions, and learn how to write *equilibrium-constant expressions* for homogeneous reactions.

15.3 UNDERSTANDING AND WORKING WITH EQUILIBRIUM CONSTANTS

We learn to interpret the magnitude of an equilibrium constant and how its value depends on the way the corresponding chemical equation is expressed.

15.4 HETEROGENEOUS EQUILIBRIA

We then learn how to write equilibrium-constant expressions for heterogeneous reactions.

TRAFFIC ENTERING AND LEAVING a city.

15.5 CALCULATING EQUILIBRIUM CONSTANTS

We see that the value of an equilibrium constant can be calculated from equilibrium concentrations of reactants and products.

15.6 APPLICATIONS OF EQUILIBRIUM CONSTANTS

We also see that equilibrium constants can be used to predict equilibrium concentrations of reactants and products and to

determine the direction in which a reaction mixture must proceed to achieve equilibrium.

15.7 LE CHÂTELIER'S PRINCIPLE

We discuss *Le Châtelier's principle*, which predicts how a system at equilibrium responds to changes in concentration, volume, pressure, and temperature.

CHEMICAL EQUILIBRIUM

TO BE IN EQUILIBRIUM IS to be in a state of balance. A tug of war in which the two sides pull with equal force so that the rope does not move is an example of a *static* equilibrium, one in which an object is at rest. Equilibria can also be *dynamic*, as illustrated in the chapter-opening photograph, which shows cars traveling

in both directions over a bridge that serves as the entry to a city. If the rate at which cars leave the city equals the rate at which they enter, the two opposing processes are in balance, and the net number of cars in the city is constant.

We have already encountered several instances of dynamic equilibrium. For example, the vapor above a liquid in a closed container is in equilibrium with the liquid phase \rightleftharpoons (Section 11.5), which means that the rate at which molecules escape from the liquid into the gas phase equals the rate at which molecules in the gas phase become part of the liquid. Similarly, in a saturated sodium chloride solution in contact with undissolved sodium chloride, the solid is in equilibrium with the ions dispersed in water. \rightleftharpoons (Section 13.2) The rate at which ions leave the solid surface equals the rate at which other ions leave the liquid and become part of the solid.

In this chapter we consider dynamic equilibria in chemical reactions. **Chemical equilibrium** occurs when opposing reactions proceed at equal rates: The rate at which the products form from the reactants equals the rate at which the reactants form from the products. As a result, concentrations cease to change, making the reaction appear to be

stopped. Chemical equilibria are involved in many natural phenomena and play important roles in many industrial processes. In this and the next two chapters, we will explore chemical equilibrium in some detail. Later, in Chapter 19, we will learn how to relate chemical equilibria to thermodynamics. Here we learn how to express the equilibrium state of a reaction in quantitative terms and study the factors that determine the relative concentrations of reactants and products in equilibrium mixtures.

15.1 THE CONCEPT OF EQUILIBRIUM

Let's examine a simple chemical reaction to see how it reaches an *equilibrium state*—a mixture of reactants and products whose concentrations no longer change with time. We begin with N_2O_4 , a colorless substance that dissociates to form brown NO_2 . **▼ FIGURE 15.1** shows a sample of frozen N_2O_4 inside a sealed tube. The solid N_2O_4 vaporizes as it is warmed above its boiling point (21.2°C), and the gas turns darker as the colorless N_2O_4 gas dissociates into brown NO_2 gas. Eventually, even though there is still N_2O_4 in the tube, the color stops getting darker because the system reaches equilibrium. We are left with an *equilibrium mixture* of N_2O_4 and NO_2 in which the concentrations of the gases no longer change as time passes. Because the reaction is in a closed system, where no gases can escape, equilibrium will eventually be reached.

GO FIGURE

How can you tell if you are at equilibrium?

▲ FIGURE 15.1 The equilibrium between NO_2 and N_2O_4 .

The equilibrium mixture results because the reaction is *reversible*: N_2O_4 can form NO_2 , and NO_2 can form N_2O_4 . This situation is represented by writing the equation for the reaction with two half arrows pointing in opposite directions: \rightleftharpoons (Section 4.1)

We can analyze this equilibrium using our knowledge of kinetics. Let's call the decomposition of N_2O_4 the forward reaction and the formation of N_2O_4 the reverse reaction. In this case, both the forward reaction and the reverse reaction are elementary reactions. As we learned in Section 14.6, the rate laws for elementary reactions can be written from their chemical equations:

At equilibrium, the rate at which NO_2 forms in the forward reaction equals the rate at which N_2O_4 forms in the reverse reaction:

$$\underset{\text{Forward reaction}}{k_f[\text{N}_2\text{O}_4]} = \underset{\text{Reverse reaction}}{k_r[\text{NO}_2]^2} \quad [15.4]$$

Rearranging this equation gives

$$\frac{[\text{NO}_2]^2}{[\text{N}_2\text{O}_4]} = \frac{k_f}{k_r} = \text{a constant} \quad [15.5]$$

From Equation 15.5 we see that the quotient of two rate constants is another constant. We also see that, at equilibrium, the ratio of the concentration terms equals this same constant. (We consider this constant, called the equilibrium constant, in Section 15.2.) It makes no difference whether we start with N_2O_4 or with NO_2 , or even with some mixture of the two. At equilibrium, at a given temperature, the ratio equals a specific value. Thus, there is an important constraint on the proportions of N_2O_4 and NO_2 at equilibrium.

Once equilibrium is established, the concentrations of N_2O_4 and NO_2 no longer change, as shown in **FIGURE 15.2(a)**. However, the fact that the composition of the equilibrium mixture remains constant with time does not mean that N_2O_4 and NO_2 stop reacting. On the contrary, the equilibrium is *dynamic*—which means some N_2O_4 is always converting to NO_2 and some NO_2 is always converting to N_2O_4 . At equilibrium, however, the two processes occur at the same rate, as shown in Figure 15.2(b).

We learn several important lessons about equilibrium from this example:

- At equilibrium, the concentrations of reactants and products no longer change with time.
- For equilibrium to occur, neither reactants nor products can escape from the system.
- At equilibrium, a particular ratio of concentration terms equals a constant.

GO FIGURE

At equilibrium, are the concentrations of NO_2 and N_2O_4 equal?

FIGURE 15.2 Achieving chemical equilibrium in the $\text{N}_2\text{O}_4(\text{g}) \rightleftharpoons 2 \text{NO}_2(\text{g})$ reaction. Equilibrium occurs when the rate of the forward reaction equals the rate of the reverse reaction.

GIVE IT SOME THOUGHT

- Which quantities are equal in a dynamic equilibrium?
- If the rate constant for the forward reaction in Equation 15.1 is larger than the rate constant for the reverse reaction, will the constant in Equation 15.5 be greater than 1 or smaller than 1?

15.2 THE EQUILIBRIUM CONSTANT

A reaction in which reactants convert to products and products convert to reactants in the same reaction vessel naturally leads to an equilibrium, regardless of how complicated the reaction is and regardless of the nature of the kinetic processes for the forward and reverse reactions. Consider the synthesis of ammonia from nitrogen and hydrogen:

This reaction is the basis for the **Haber process**, which is critical for the production of fertilizers and therefore critical to the world's food supply. In the Haber process, N_2 and H_2 react at high pressure and temperature in the presence of a catalyst to form ammonia. In a closed system, however, the reaction does not lead to complete consumption of the N_2 and H_2 . Rather, at some point the reaction appears to stop with all three components of the reaction mixture present at the same time.

How the concentrations of H_2 , N_2 , and NH_3 vary with time is shown in  **FIGURE 15.3**. Notice that an equilibrium mixture is obtained regardless of whether we begin with N_2 and H_2 or with NH_3 . *The equilibrium condition is reached from either direction.*

GIVE IT SOME THOUGHT

How do we know when equilibrium has been reached in a chemical reaction?

An expression similar to Equation 15.5 governs the concentrations of N_2 , H_2 , and NH_3 at equilibrium. If we were to systematically change the relative amounts of the three gases in the starting mixture and then analyze each equilibrium mixture, we could determine the relationship among the equilibrium concentrations.

Chemists carried out studies of this kind on other chemical systems in the nineteenth century before Haber's work. In 1864, Cato Maximilian Guldberg (1836–1902) and Peter Waage (1833–1900) postulated their **law of mass action**, which expresses, for any reaction, the relationship between the concentrations of the reactants and products present at equilibrium. Suppose we have the general equilibrium equation

where A, B, D, and E are the chemical species involved and a , b , d , and e are their coefficients in the balanced chemical equation. According to the law of mass action, the equilibrium condition is described by the expression

$$K_c = \frac{[\text{D}]^d [\text{E}]^e}{[\text{A}]^a [\text{B}]^b} \quad \begin{array}{l} \longleftarrow \text{products} \\ \longleftarrow \text{reactants} \end{array} \quad [15.8]$$

We call this relationship the **equilibrium-constant expression** (or merely the *equilibrium expression*) for the reaction. The constant K_c , the **equilibrium constant**, is the numerical value obtained when we substitute molar equilibrium concentrations

 **FIGURE 15.3** The same equilibrium is reached whether we start with only reactants (N_2 and H_2) or with only product (NH_3).

CHEMISTRY PUT TO WORK

The Haber Process

The quantity of food required to feed the ever-increasing human population far exceeds that provided by nitrogen-fixing plants. ∞ (Section 14.7) Therefore, human agriculture requires substantial amounts of ammonia-based fertilizers for croplands. Of all the chemical reactions that humans have learned to control for their own purposes, the synthesis of ammonia from hydrogen and atmospheric nitrogen is one of the most important.

In 1912 the German chemist Fritz Haber (1868–1934) developed the Haber process (Equation 15.6). The process is sometimes also called the *Haber–Bosch process* to honor Karl Bosch, the engineer who developed the industrial process on a large scale. The engineering needed to implement the Haber process requires the use of temperatures and pressures (approximately 500 °C and 200 to 600 atm) that were difficult to achieve at that time.

◀ **FIGURE 15.4** Liquid ammonia used as fertilizer by direct injection into soil.

The Haber process provides a historically interesting example of the complex impact of chemistry on our lives. At the start of World War I, in 1914, Germany depended on nitrate deposits in Chile for the nitrogen-containing compounds needed to manufacture explosives. During the war, the Allied naval blockade of South America cut off this supply. However, by using the Haber reaction to fix nitrogen from air, Germany was able to continue to produce explosives. Experts have estimated that World War I would have ended before 1918 had it not been for the Haber process.

From these unhappy beginnings as a major factor in international warfare, the Haber process has become the world's principal source of fixed nitrogen. The same process that prolonged World War I has enabled the manufacture of fertilizers that have increased crop yields, thereby saving millions of people from starvation. About 40 billion pounds of ammonia are manufactured annually in the United States, mostly by the Haber process. The ammonia can be applied directly to the soil (▼ **FIGURE 15.4**), or it can be converted into ammonium salts that are also used as fertilizers.

Haber was a patriotic German who gave enthusiastic support to his nation's war effort. He served as chief of Germany's Chemical Warfare Service during World War I and developed the use of chlorine as a poison-gas weapon. Consequently, the decision to award him the Nobel Prize in Chemistry in 1918 was the subject of considerable controversy and criticism. The ultimate irony, however, came in 1933 when Haber was expelled from Germany because he was Jewish.

RELATED EXERCISES: 15.46 and 15.76

into the equilibrium-constant expression. The subscript *c* on the *K* indicates that concentrations expressed in molarity are used to evaluate the constant.

The numerator of the equilibrium-constant expression is the product of the concentrations of all substances on the product side of the equilibrium equation, each raised to a power equal to its coefficient in the balanced equation. The denominator is similarly derived from the reactant side of the equilibrium equation. Thus, for the Haber process, $\text{N}_2(\text{g}) + 3 \text{H}_2(\text{g}) \rightleftharpoons 2 \text{NH}_3(\text{g})$, the equilibrium-constant expression is

$$K_c = \frac{[\text{NH}_3]^2}{[\text{N}_2][\text{H}_2]^3} \quad [15.9]$$

Once we know the balanced chemical equation for a reaction that reaches equilibrium, we can write the equilibrium-constant expression even if we do not know the reaction mechanism. *The equilibrium-constant expression depends only on the stoichiometry of the reaction, not on its mechanism.*

The value of the equilibrium constant at any given temperature does not depend on the initial amounts of reactants and products. It also does not matter whether other substances are present, as long as they do not react with a reactant or a product. The value of K_c depends only on the particular reaction and on the temperature.

SAMPLE EXERCISE 15.1 Writing Equilibrium-Constant Expressions

Write the equilibrium expression for K_c for the following reactions:

- (a) $2 \text{O}_3(g) \rightleftharpoons 3 \text{O}_2(g)$
 (b) $2 \text{NO}(g) + \text{Cl}_2(g) \rightleftharpoons 2 \text{NOCl}(g)$
 (c) $\text{Ag}^+(aq) + 2 \text{NH}_3(aq) \rightleftharpoons \text{Ag}(\text{NH}_3)_2^+(aq)$

SOLUTION

Analyze We are given three equations and are asked to write an equilibrium-constant expression for each.

Plan Using the law of mass action, we write each expression as a quotient having the product concentration terms in the numerator and the reactant concentration terms in the denominator. Each concentration term is raised to the power of its coefficient in the balanced chemical equation.

Solve

$$\text{(a) } K_c = \frac{[\text{O}_2]^3}{[\text{O}_3]^2} \quad \text{(b) } K_c = \frac{[\text{NOCl}]^2}{[\text{NO}]^2[\text{Cl}_2]} \quad \text{(c) } K_c = \frac{[\text{Ag}(\text{NH}_3)_2^+]}{[\text{Ag}^+][\text{NH}_3]^2}$$

PRACTICE EXERCISE

Write the equilibrium-constant expression K_c for (a) $\text{H}_2(g) + \text{I}_2(g) \rightleftharpoons 2 \text{HI}(g)$,
 (b) $\text{Cd}^{2+}(aq) + 4 \text{Br}^-(aq) \rightleftharpoons \text{CdBr}_4^{2-}(aq)$.

$$\text{Answers: (a) } K_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]} \quad \text{(b) } K_c = \frac{[\text{CdBr}_4^{2-}]}{[\text{Cd}^{2+}][\text{Br}^-]^4}$$

Evaluating K_c

We can illustrate how the law of mass action was discovered empirically and demonstrate that the equilibrium constant is independent of starting concentrations by examining a series of experiments involving dinitrogen tetroxide and nitrogen dioxide:

We start with several sealed tubes containing different concentrations of NO_2 and N_2O_4 . The tubes are kept at 100°C until equilibrium is reached. We then analyze the mixtures and determine the equilibrium concentrations of NO_2 and N_2O_4 , which are shown in

TABLE 15.1.

To evaluate K_c , we insert the equilibrium concentrations into the equilibrium-constant expression. For example, using Experiment 1 data, $[\text{NO}_2] = 0.0172 \text{ M}$ and $[\text{N}_2\text{O}_4] = 0.00140 \text{ M}$, we find

$$K_c = \frac{[\text{NO}_2]^2}{[\text{N}_2\text{O}_4]} = \frac{[0.0172]^2}{0.00140} = 0.211$$

TABLE 15.1 • Initial and Equilibrium Concentrations of $\text{N}_2\text{O}_4(g)$ and $\text{NO}_2(g)$ at 100°C

Experiment	Initial $[\text{N}_2\text{O}_4] (M)$	Initial $[\text{NO}_2] (M)$	Equilibrium $[\text{N}_2\text{O}_4] (M)$	Equilibrium $[\text{NO}_2] (M)$	K_c
1	0.0	0.0200	0.00140	0.0172	0.211
2	0.0	0.0300	0.00280	0.0243	0.211
3	0.0	0.0400	0.00452	0.0310	0.213
4	0.0200	0.0	0.00452	0.0310	0.213

Proceeding in the same way, the values of K_c for the other samples are calculated. Note from Table 15.1 that the value for K_c is constant (within the limits of experimental error) even though the initial concentrations vary. Furthermore, Experiment 4 shows that equilibrium can be achieved beginning with N_2O_4 rather than with NO_2 . That is, equilibrium can be approached from either direction. ► **FIGURE 15.5** shows how Experiments 3 and 4 result in the same equilibrium mixture even though the two experiments start with very different NO_2 concentrations.

Notice that no units are given for K_c either in Table 15.1 or in the calculation we just did using Experiment 1 data. It is common practice to write equilibrium constants without units for reasons that we address later in this section.

Recall that we began our discussion of equilibrium in terms of rates. Equation 15.5 shows that K_c is equal to k_f/k_r , the ratio of the forward rate constant to the reverse rate constant. For the $\text{N}_2\text{O}_4/\text{NO}_2$ reaction, $K_c = 0.212$, which means that k_r is 4.72 times as large as k_f (since $1/0.212 = 4.72$). It is not possible to obtain the absolute value of either rate constant knowing only the value of K_c .

▲ GIVE IT SOME THOUGHT

How does the value of K_c in Equation 15.10 depend on the starting concentrations of NO_2 and N_2O_4 ?

Equilibrium Constants in Terms of Pressure, K_p

When the reactants and products in a chemical reaction are gases, we can formulate the equilibrium-constant expression in terms of partial pressures. When partial pressures in atmospheres are used in the expression, we denote the equilibrium constant K_p (where the subscript p stands for pressure). For the general reaction in Equation 15.7, we have

$$K_p = \frac{(P_D)^d (P_E)^e}{(P_A)^a (P_B)^b} \quad [15.11]$$

where P_A is the partial pressure of A in atmospheres, P_B is the partial pressure of B in atmospheres, and so forth. For example, for our $\text{N}_2\text{O}_4/\text{NO}_2$ reaction we have

$$K_p = \frac{(P_{\text{NO}_2})^2}{P_{\text{N}_2\text{O}_4}}$$

▲ GIVE IT SOME THOUGHT

What is the difference between the equilibrium constant K_c and the equilibrium constant K_p ?

For a given reaction, the numerical value of K_c is generally different from the numerical value of K_p . We must therefore take care to indicate, via subscript c or p , which constant we are using. It is possible, however, to calculate one from the other using the ideal-gas equation: ∞ (Section 10.4)

$$PV = nRT, \text{ so } P = \frac{n}{V}RT \quad [15.12]$$

The usual units for n/V are mol/L, which equals molarity, M . For substance A in our generic reaction, we therefore see that

$$P_A = \frac{n_A}{V}RT = [A]RT \quad [15.13]$$

When we substitute Equation 15.13 and like expressions for the other gaseous components of the reaction into Equation 15.11, we obtain a general expression relating K_p and K_c :

$$K_p = K_c(RT)^{\Delta n} \quad [15.14]$$

The quantity Δn is the change in the number of moles of gas in the balanced chemical equation. It equals the sum of the coefficients of the gaseous products minus the sum of the coefficients of the gaseous reactants:

$$\Delta n = (\text{moles of gaseous product}) - (\text{moles of gaseous reactant}) \quad [15.15]$$

▲ **FIGURE 15.5** The same equilibrium mixture is produced regardless of the initial NO_2 concentration. The concentration of NO_2 either increases or decreases until equilibrium is reached.

For example, in the $\text{N}_2\text{O}_4(\text{g}) \rightleftharpoons 2 \text{NO}_2(\text{g})$ reaction, there are two moles of product NO_2 and one mole of reactant N_2O_4 . Therefore, $\Delta n = 2 - 1 = 1$, and $K_p = K_c(RT)$ for this reaction.

From Equation 15.14, we see that $K_p = K_c$ only when the same number of moles of gas appears on both sides of the balanced chemical equation, so that $\Delta n = 0$.

SAMPLE EXERCISE 15.2 Converting between K_c and K_p

For the Haber process,

$K_c = 9.60$ at 300°C . Calculate K_p for this reaction at this temperature.

SOLUTION

Analyze We are given K_c for a reaction and asked to calculate K_p .

Plan The relationship between K_c and K_p is given by Equation 15.14. To apply that equation, we must determine Δn by comparing the number of moles of product with the number of moles of reactants (Equation 15.15).

Solve With 2 mol of gaseous products (2NH_3) and 4 mol of gaseous reactants ($1 \text{N}_2 + 3 \text{H}_2$), $\Delta n = 2 - 4 = -2$. (Remember that Δ functions are always based on *products minus reactants*.) The temperature is $273 + 300 = 573 \text{K}$. The value for the ideal-gas constant, R , is $0.08206 \text{L}\cdot\text{atm}/\text{mol}\cdot\text{K}$. Using $K_c = 9.60$, we therefore have

$$K_p = K_c(RT)^{\Delta n} = (9.60)(0.08206 \times 573)^{-2} = \frac{(9.60)}{(0.08206 \times 573)^2} = 4.34 \times 10^{-3}$$

PRACTICE EXERCISE

For the equilibrium $2 \text{SO}_3(\text{g}) \rightleftharpoons 2 \text{SO}_2(\text{g}) + \text{O}_2(\text{g})$, K_c is 4.08×10^{-3} at 1000K . Calculate the value for K_p .

Answer: 0.335

Equilibrium Constants and Units

You may wonder why equilibrium constants are reported without units. The equilibrium constant is related to the kinetics of a reaction as well as to the thermodynamics. (We explore this latter connection in Chapter 19.) Equilibrium constants derived from thermodynamic measurements are defined in terms of *activities* rather than concentrations or partial pressures.

The activity of any substance in an *ideal* mixture is the ratio of the concentration or pressure of the substance either to a reference concentration (1M) or to a reference pressure (1atm). For example, if the concentration of a substance in an equilibrium mixture is 0.010M , its activity is $0.010 \text{M}/1 \text{M} = 0.010$. The units of such ratios always cancel and, consequently, activities have no units. Furthermore, the numerical value of the activity equals the concentration. For pure solids and pure liquids, the situation is even simpler because the activities then merely equal 1 (again with no units).

In real systems, activities are also ratios that have no units. Even though these activities may not be exactly numerically equal to concentrations, we will ignore the differences. All we need to know at this point is that activities have no units. As a result, the *thermodynamic equilibrium constants* derived from them also have no units. It is therefore common practice to write all types of equilibrium constants without units, a practice that we adhere to in this text. In more advanced chemistry courses, you may make more rigorous distinctions between concentrations and activities.

GIVE IT SOME THOUGHT

If the concentration of N_2O_4 in an equilibrium mixture is 0.00140M , what is its activity? (Assume the solution is ideal.)

15.3 UNDERSTANDING AND WORKING WITH EQUILIBRIUM CONSTANTS

Before doing calculations with equilibrium constants, it is valuable to understand what the magnitude of an equilibrium constant can tell us about the relative concentrations of reactants and products in an equilibrium mixture. It is also useful to consider how the magnitude of any equilibrium constant depends on how the chemical equation is expressed.

The Magnitude of Equilibrium Constants

The magnitude of the equilibrium constant for a reaction gives us important information about the composition of the equilibrium mixture. For example, consider the experimental data for the reaction of carbon monoxide gas and chlorine gas at 100 °C to form phosgene (COCl₂), a toxic gas used in the manufacture of certain polymers and insecticides:

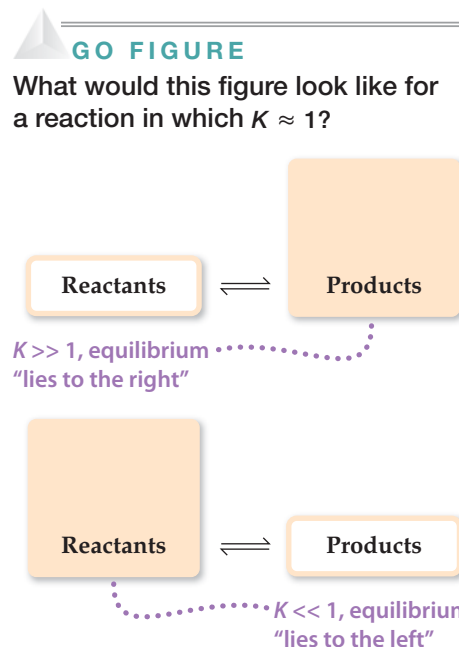

For the equilibrium constant to be so large, the numerator of the equilibrium-constant expression must be approximately a billion (10⁹) times larger than the denominator. Thus, the equilibrium concentration of COCl₂ must be much greater than that of CO or Cl₂, and in fact this is just what we find experimentally. We say that this equilibrium *lies to the right* (that is, toward the product side). Likewise, a very small equilibrium constant indicates that the equilibrium mixture contains mostly reactants. We then say that the equilibrium *lies to the left*. In general,

If $K \gg 1$ (large K): Equilibrium lies to right, products predominate

If $K \ll 1$ (small K): Equilibrium lies to left, reactants predominate

These situations are summarized in ► **FIGURE 15.6**. Remember, it is forward and reverse *rates* that are equal at equilibrium, not concentrations.

▲ **FIGURE 15.6** Relationship between magnitude of K and composition of an equilibrium mixture.

SAMPLE EXERCISE 15.3 Interpreting the Magnitude of an Equilibrium Constant

The following diagrams represent three systems at equilibrium, all in the same-size containers. (a) Without doing any calculations, rank the systems in order of increasing K_c . (b) If the volume of the containers is 1.0 L and each sphere represents 0.10 mol, calculate K_c for each system.

SOLUTION

Analyze We are asked to judge the relative magnitudes of three equilibrium constants and then to calculate them.

Plan (a) The more product present at equilibrium, relative to reactant, the larger the equilibrium constant. (b) The equilibrium constant is given by Equation 15.8.

Solve

(a) Each box contains 10 spheres. The amount of product in each varies as follows: (i) 6, (ii) 1, (iii) 8. Therefore, the equilibrium constant varies in the order (ii) < (i) < (iii), from smallest (most reactant) to largest (most products).

(b) In (i) we have 0.60 mol/L product and 0.40 mol/L reactant, giving $K_c = 0.60/0.40 = 1.5$. (You will get the same result by merely dividing the number of spheres of each kind: 6 spheres/4 spheres = 1.5.) In (ii) we have 0.10 mol/L product and 0.90 mol/L reactant, giving $K_c = 0.10/0.90 = 0.11$ (or 1 sphere/9 spheres = 0.11). In (iii) we have 0.80 mol/L product and 0.20 mol/L reactant, giving $K_c = 0.80/0.20 = 4.0$ (or 8 spheres/2 spheres = 4.0). These calculations verify the order in (a).

Comment Imagine a drawing that represents a reaction with a very small or very large value of K_c . For example, what would the drawing look like if $K_c = 1 \times 10^{-5}$? In that case there would need to be 100,000 reactant molecules for only 1 product molecule. But then, that would be impractical to draw.

PRACTICE EXERCISE

For the reaction $\text{H}_2(\text{g}) + \text{I}_2(\text{g}) \rightleftharpoons 2 \text{HI}(\text{g})$, $K_p = 794$ at 298 K and $K_p = 55$ at 700 K. Is the formation of HI favored more at the higher or lower temperature?

Answer: at the lower temperature because K_p is larger at the lower temperature

The Direction of the Chemical Equation and K

We have seen that we can represent the $\text{N}_2\text{O}_4/\text{NO}_2$ equilibrium as

We could equally well consider this equilibrium in terms of the reverse reaction:

The equilibrium expression is then

$$K_c = \frac{[\text{N}_2\text{O}_4]}{[\text{NO}_2]^2} = \frac{1}{0.212} = 4.72 \quad (\text{at } 100^\circ\text{C}) \quad [15.17]$$

Equation 15.17 is the reciprocal of the expression in Equation 15.16. *The equilibrium-constant expression for a reaction written in one direction is the reciprocal of the expression for the reaction written in the reverse direction.* Consequently, the numerical value of the equilibrium constant for the reaction written in one direction is the reciprocal of that for the reverse reaction. Both expressions are equally valid, but it is meaningless to say that the equilibrium constant for the equilibrium between NO_2 and N_2O_4 is “0.212” or “4.72” unless we indicate how the equilibrium reaction is written and specify the temperature. Therefore, whenever you are using an equilibrium constant, you should always write the associated balanced chemical equation.

SAMPLE EXERCISE 15.4 Evaluating an Equilibrium Constant When an Equation Is Reversed

For the reaction

that is run at 25 °C, $K_c = 1 \times 10^{-30}$. Use this information to write the equilibrium-constant expression and calculate the equilibrium constant for the reaction

SOLUTION

Analyze We are asked to write the equilibrium-constant expression for a reaction and to determine the value of K_c given the chemical equation and equilibrium constant for the reverse reaction.

Plan The equilibrium-constant expression is a quotient of products over reactants, each raised to a power equal to its coefficient in the balanced equation. The value of the equilibrium constant is the reciprocal of that for the reverse reaction.

Solve

Writing products over reactants, we have

$$K_c = \frac{[\text{N}_2][\text{O}_2]}{[\text{NO}]^2}$$

Both the equilibrium-constant expression and the numerical value of the equilibrium constant are the reciprocals of those for the formation of NO from N₂ and O₂:

$$K_c = \frac{[\text{N}_2][\text{O}_2]}{[\text{NO}]^2} = \frac{1}{1 \times 10^{-30}} = 1 \times 10^{30}$$

Comment Regardless of the way we express the equilibrium among NO, N₂, and O₂, at 25 °C it lies on the side that favors N₂ and O₂. Thus, the equilibrium mixture will contain mostly N₂ and O₂ with very little NO present.

PRACTICE EXERCISE

For $\text{N}_2(\text{g}) + 3 \text{H}_2(\text{g}) \rightleftharpoons 2 \text{NH}_3(\text{g})$, $K_p = 4.34 \times 10^{-3}$ at 300 °C. What is the value of K_p for the reverse reaction?

Answer: 2.30×10^2

Relating Chemical Equation Stoichiometry and Equilibrium Constants

There are many ways to write a balanced chemical equation for a given reaction. For example, if we multiply Equation 15.1, $\text{N}_2\text{O}_4(\text{g}) \rightleftharpoons 2 \text{NO}_2(\text{g})$ by 2, we have

This chemical equation is balanced and might be written this way in some contexts. Therefore, the equilibrium-constant expression for this equation is

$$K_c = \frac{[\text{NO}_2]^4}{[\text{N}_2\text{O}_4]^2}$$

which is the square of the equilibrium-constant expression given in Equation 15.10 for the reaction as written in Equation 15.1: $[\text{NO}_2]^2/[\text{N}_2\text{O}_4]$. Because the new equilibrium-constant expression equals the original expression squared, the new equilibrium constant K_c equals the original constant squared: $0.212^2 = 0.0449$ (at 100 °C). Once again, it is important to remember that you must relate each equilibrium constant you work with to a *specific* balanced chemical equation. The concentrations of the substances in the equilibrium mixture will be the same no matter how you write the chemical equation, but the value of K_c you calculate depends completely on how you write the reaction.

GIVE IT SOME THOUGHT

How does the magnitude of K_p for the reaction $2 \text{HI}(\text{g}) \rightleftharpoons \text{H}_2(\text{g}) + \text{I}_2(\text{g})$ change if the equilibrium is written $6 \text{HI}(\text{g}) \rightleftharpoons 3 \text{H}_2(\text{g}) + 3 \text{I}_2(\text{g})$?

It is also possible to calculate the equilibrium constant for a reaction if we know the equilibrium constants for other reactions that add up to give us the one we want, similar to Hess's law. ∞ (Section 5.6) For example, consider the following two reactions, their equilibrium-constant expressions, and their equilibrium constants at 100 °C:

The net sum of these two equations is

You can prove algebraically that the equilibrium-constant expression for reaction 3 is the product of the expressions for reactions 1 and 2:

$$K_c = \frac{[\text{NO}]^2[\text{BrCl}]^2}{[\text{NOBr}]^2[\text{Cl}_2]} = \frac{[\text{NO}]^2[\text{Br}_2]}{[\text{NOBr}]^2} \times \frac{[\text{BrCl}]^2}{[\text{Br}_2][\text{Cl}_2]}$$

Thus,

$$K_{c3} = (K_{c1})(K_{c2}) = (0.014)(7.2) = 0.10$$

To summarize:

1. The equilibrium constant of a reaction in the *reverse* direction is the *inverse* (or *reciprocal*) of the equilibrium constant of the reaction in the forward direction:

2. The equilibrium constant of a reaction that has been *multiplied* by a number is equal to the original equilibrium constant raised to a *power* equal to that number.

3. The equilibrium constant for a net reaction made up of *two or more reactions* is the *product* of the equilibrium constants for the individual reactions:

SAMPLE EXERCISE 15.5 Combining Equilibrium Expressions

Given the reactions

determine the value of K_c for the reaction

SOLUTION

Analyze We are given two equilibrium equations and the corresponding equilibrium constants and are asked to determine the equilibrium constant for a third equation, which is related to the first two.

Plan We cannot simply add the first two equations to get the third. Instead, we need to determine how to manipulate the equations to come up with the steps that will add to give us the desired equation.

Solve

If we multiply the first equation by 2 and make the corresponding change to its equilibrium constant (raising to the power 2), we get

Reversing the second equation and again making the corresponding change to its equilibrium constant (taking the reciprocal) gives

Now we have two equations that sum to give the net equation, and we can multiply the individual K_c values to get the desired equilibrium constant.

PRACTICE EXERCISE

Given that, at 700 K, $K_p = 54.0$ for the reaction $\text{H}_2(g) + \text{I}_2(g) \rightleftharpoons 2\text{HI}(g)$ and $K_p = 1.04 \times 10^{-4}$ for the reaction $\text{N}_2(g) + 3\text{H}_2(g) \rightleftharpoons 2\text{NH}_3(g)$, determine the value of K_p for the reaction $2\text{NH}_3(g) + 3\text{I}_2(g) \rightleftharpoons 6\text{HI}(g) + \text{N}_2(g)$ at 700 K.

Answer: $\frac{(54.0)^3}{1.04 \times 10^{-4}} = 1.51 \times 10^9$

15.4 HETEROGENEOUS EQUILIBRIA

Many equilibria involve substances that are all in the same phase, usually gas or liquid. Such equilibria are called **homogeneous equilibria**. In some cases, however, the substances in equilibrium are in different phases, giving rise to **heterogeneous equilibria**. As an example of the latter, consider the equilibrium that occurs when solid lead(II) chloride dissolves in water to form a saturated solution:

This system consists of a solid in equilibrium with two aqueous species. If we want to write the equilibrium-constant expression for this process, we encounter a problem we have not encountered previously: How do we express the concentration of a solid? Although we can express that concentration in moles per unit volume, it is unnecessary to do so in writing equilibrium-constant expressions. *Whenever a pure solid or a pure liquid is involved in a heterogeneous equilibrium, its concentration is not included in the equilibrium-constant expression.* Thus, the equilibrium-constant expression for the reaction of Equation 15.18 is

$$K_c = [\text{Pb}^{2+}][\text{Cl}^-]^2 \quad [15.19]$$

Even though $\text{PbCl}_2(s)$ does not appear in the equilibrium-constant expression, it must be present for equilibrium to occur.

The fact that pure solids and pure liquids are excluded from equilibrium-constant expressions can be explained in two ways. First, the concentration of a pure solid or liquid has a constant value. If the mass of a solid is doubled, its volume also doubles. Thus, its concentration, which relates to the ratio of mass to volume, stays the same. Because equilibrium-constant expressions include terms only for reactants and products whose concentrations can change during a chemical reaction, the concentrations of pure solids and pure liquids are omitted.

The omission can also be rationalized in a second way. Recall from Section 15.2 that what is substituted into a thermodynamic equilibrium expression is the activity of each substance, which is a ratio of the concentration to a reference value. For a pure substance, the reference value is the concentration of the pure substance, so that the activity of any pure solid or liquid is always 1.

GIVE IT SOME THOUGHT

Write the equilibrium-constant expression for the evaporation of water, $\text{H}_2\text{O}(l) \rightleftharpoons \text{H}_2\text{O}(g)$, in terms of partial pressures.

Decomposition of calcium carbonate is another example of a heterogeneous reaction:

Omitting the concentrations of the solids from the equilibrium-constant expression gives

$$K_c = [\text{CO}_2] \quad \text{and} \quad K_p = P_{\text{CO}_2}$$

These equations tell us that at a given temperature, an equilibrium among CaCO_3 , CaO , and CO_2 always leads to the same CO_2 partial pressure as long as all three components are present. As shown in ► **FIGURE 15.7**, we have the same CO_2 pressure regardless of the relative amounts of CaO and CaCO_3 .

SAMPLE EXERCISE 15.6 Writing Equilibrium-Constant Expressions for Heterogeneous Reactions

Write the equilibrium-constant expression K_c for

GO FIGURE

Imagine starting with only CaO in a bell jar and adding $\text{CO}_2(g)$ to make its pressure the same as it is in these two bell jars. How does the equilibrium concentration of $\text{CO}_2(g)$ in your jar compare with the $\text{CO}_2(g)$ equilibrium concentration in these two jars?

Large amount of CaCO_3 ,
small amount of CaO ,
gas pressure P

Small amount of CaCO_3 ,
large amount of CaO ,
gas pressure still P

▲ **FIGURE 15.7** At a given temperature, the equilibrium pressure of CO_2 in the bell jars is the same no matter how much of each solid is present.

SOLUTION

Analyze We are given two chemical equations, both for heterogeneous equilibria, and asked to write the corresponding equilibrium-constant expressions.

Plan We use the law of mass action, remembering to omit any pure solids and pure liquids from the expressions.

Solve

(a) The equilibrium-constant expression is

$$K_c = \frac{[\text{CO}]}{[\text{CO}_2][\text{H}_2]}$$

Because H_2O appears in the reaction as a liquid, its concentration does not appear in the equilibrium-constant expression.

(b) The equilibrium-constant expression is

$$K_c = \frac{[\text{CO}_2]^2}{[\text{CO}]^2}$$

Because SnO_2 and Sn are pure solids, their concentrations do not appear in the equilibrium-constant expression.

PRACTICE EXERCISE

Write the following equilibrium-constant expressions:

Answers: (a) $K_c = \frac{[\text{Cr}^{3+}]}{[\text{Ag}^+]^3}$ (b) $K_p = \frac{(P_{\text{H}_2})^4}{(P_{\text{H}_2\text{O}})^4}$

SAMPLE EXERCISE 15.7 Analyzing a Heterogeneous Equilibrium

Each of these mixtures was placed in a closed container and allowed to stand:

- (a) $\text{CaCO}_3(s)$
- (b) $\text{CaO}(s)$ and $\text{CO}_2(g)$ at a pressure greater than the value of K_p
- (c) $\text{CaCO}_3(s)$ and $\text{CO}_2(g)$ at a pressure greater than the value of K_p
- (d) $\text{CaCO}_3(s)$ and $\text{CaO}(s)$

Determine whether or not each mixture can attain the equilibrium

**SOLUTION**

Analyze We are asked which of several combinations of species can establish an equilibrium between calcium carbonate and its decomposition products, calcium oxide and carbon dioxide.

Plan For equilibrium to be achieved, it must be possible for both the forward process and the reverse process to occur. For the forward process to occur, there must be some calcium carbonate present. For the reverse process to occur, there must be both calcium oxide and carbon dioxide. In both cases, either the necessary compounds may be present initially or they may be formed by reaction of the other species.

Solve Equilibrium can be reached in all cases except (c) as long as sufficient quantities of solids are present. (a) CaCO_3 simply decomposes, forming $\text{CaO}(s)$ and $\text{CO}_2(g)$ until the equilibrium pressure of CO_2 is attained. There must be enough CaCO_3 , however, to allow the CO_2 pressure to reach equilibrium. (b) CO_2 continues to combine with CaO until the partial pressure of the CO_2 decreases to the equilibrium value. (c) There is no CaO present, so equilibrium cannot be attained because there is no way the CO_2 pressure can decrease to its equilibrium value (which would require some of the CO_2 to react with CaO). (d) The situation is essentially the same as in (a): CaCO_3 decomposes until equilibrium is attained. The presence of CaO initially makes no difference.

PRACTICE EXERCISE

When added to $\text{Fe}_3\text{O}_4(s)$ in a closed container, which one of the following substances — $\text{H}_2(g)$, $\text{H}_2\text{O}(g)$, $\text{O}_2(g)$ — allows equilibrium to be established in the reaction $3 \text{Fe}(s) + 4 \text{H}_2\text{O}(g) \rightleftharpoons \text{Fe}_3\text{O}_4(s) + 4 \text{H}_2(g)$?

Answer: $\text{H}_2(g)$

When a solvent is a reactant or product in an equilibrium, its concentration is omitted from the equilibrium-constant expression, provided the concentrations of reactants and products are low, so that the solvent is essentially a pure substance. Applying this guideline to an equilibrium involving water as a solvent,

gives an equilibrium-constant expression that does not contain $[\text{H}_2\text{O}]$:

$$K_c = \frac{[\text{OH}^-][\text{HCO}_3^-]}{[\text{CO}_3^{2-}]} \quad [15.21]$$

GIVE IT SOME THOUGHT

Write the equilibrium-constant expression for the reaction $\text{NH}_3(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{NH}_4^+(aq) + \text{OH}^-(aq)$

15.5 CALCULATING EQUILIBRIUM CONSTANTS

If we can measure the equilibrium concentrations of all the reactants and products in a chemical reaction, as we did with the data in Table 15.1, calculating the value of the equilibrium constant is straightforward. We simply insert all the equilibrium concentrations into the equilibrium-constant expression for the reaction.

SAMPLE EXERCISE 15.8 Calculating K When All Equilibrium Concentrations Are Known

After a mixture of hydrogen and nitrogen gases in a reaction vessel is allowed to attain equilibrium at 472 °C, it is found to contain 7.38 atm H_2 , 2.46 atm N_2 , and 0.166 atm NH_3 . From these data, calculate the equilibrium constant K_p for the reaction

SOLUTION

Analyze We are given a balanced equation and equilibrium partial pressures and are asked to calculate the value of the equilibrium constant.

Plan Using the balanced equation, we write the equilibrium-constant expression. We then substitute the equilibrium partial pressures into the expression and solve for K_p .

Solve

$$K_p = \frac{(P_{\text{NH}_3})^2}{P_{\text{N}_2}(P_{\text{H}_2})^3} = \frac{(0.166)^2}{(2.46)(7.38)^3} = 2.79 \times 10^{-5}$$

PRACTICE EXERCISE

An aqueous solution of acetic acid is found to have the following equilibrium concentrations at 25 °C: $[\text{CH}_3\text{COOH}] = 1.65 \times 10^{-2} \text{ M}$; $[\text{H}^+] = 5.44 \times 10^{-4} \text{ M}$; and $[\text{CH}_3\text{COO}^-] = 5.44 \times 10^{-4} \text{ M}$. Calculate the equilibrium constant K_c for the ionization of acetic acid at 25 °C. The reaction is

Answer: 1.79×10^{-5}

Often we do not know the equilibrium concentrations of all species in an equilibrium mixture. If we know the equilibrium concentration of at least one species, however, we can generally use the stoichiometry of the reaction to deduce the equilibrium concentrations of the others. The following steps outline the procedure:

1. Tabulate all known initial and equilibrium concentrations of the species that appear in the equilibrium-constant expression.
2. For those species for which initial and equilibrium concentrations are known, calculate the change in concentration that occurs as the system reaches equilibrium.

- Use the stoichiometry of the reaction (that is, the coefficients in the balanced chemical equation) to calculate the changes in concentration for all other species in the equilibrium-constant expression.
- Use initial concentrations from step 1 and changes in concentration from step 3 to calculate any equilibrium concentrations not tabulated in step 1.
- Determine the value of the equilibrium constant.

SAMPLE EXERCISE 15.9 Calculating K from Initial and Equilibrium Concentrations

A closed system initially containing $1.000 \times 10^{-3} M \text{H}_2$ and $2.000 \times 10^{-3} M \text{I}_2$ at 448°C is allowed to reach equilibrium, and at equilibrium the HI concentration is $1.87 \times 10^{-3} M$. Calculate K_c at 448°C for the reaction taking place, which is

SOLUTION

Analyze We are given the initial concentrations of H_2 and I_2 and the equilibrium concentration of HI . We are asked to calculate the equilibrium constant K_c for $\text{H}_2(\text{g}) + \text{I}_2(\text{g}) \rightleftharpoons 2 \text{HI}(\text{g})$.

Plan We construct a table to find equilibrium concentrations of all species and then use the equilibrium concentrations to calculate the equilibrium constant.

Solve First, we tabulate the initial and equilibrium concentrations of as many species as we can. We also provide space in our table for listing the changes in concentrations. As shown, it is convenient to use the chemical equation as the heading for the table.

Second, we calculate the change in HI concentration, which is the difference between the equilibrium and initial values:

$$\text{Change in } [\text{HI}] = 1.87 \times 10^{-3} M - 0 = 1.87 \times 10^{-3} M$$

Third, we use the coefficients in the balanced equation to relate the change in $[\text{HI}]$ to the changes in $[\text{H}_2]$ and $[\text{I}_2]$:

$$\left(1.87 \times 10^{-3} \frac{\text{mol HI}}{\text{L}}\right) \left(\frac{1 \text{ mol H}_2}{2 \text{ mol HI}}\right) = 0.935 \times 10^{-3} \frac{\text{mol H}_2}{\text{L}}$$

$$\left(1.87 \times 10^{-3} \frac{\text{mol HI}}{\text{L}}\right) \left(\frac{1 \text{ mol I}_2}{2 \text{ mol HI}}\right) = 0.935 \times 10^{-3} \frac{\text{mol I}_2}{\text{L}}$$

Fourth, we calculate the equilibrium concentrations of H_2 and I_2 , using initial concentrations and changes in concentration. The equilibrium concentration equals the initial concentration minus that consumed:

$$[\text{H}_2] = 1.000 \times 10^{-3} M - 0.935 \times 10^{-3} M = 0.065 \times 10^{-3} M$$

$$[\text{I}_2] = 2.000 \times 10^{-3} M - 0.935 \times 10^{-3} M = 1.065 \times 10^{-3} M$$

Our table now looks like this (with equilibrium concentrations in blue for emphasis):

	$\text{H}_2(\text{g})$	+	$\text{I}_2(\text{g})$	\rightleftharpoons	$2 \text{HI}(\text{g})$
Initial concentration (M)	1.000×10^{-3}		2.000×10^{-3}		0
Change in concentration (M)	-0.935×10^{-3}		-0.935×10^{-3}		$+1.87 \times 10^{-3}$
Equilibrium concentration (M)	0.065×10^{-3}		1.065×10^{-3}		1.87×10^{-3}

Notice that the entries for the changes are negative when a reactant is consumed and positive when a product is formed.

Finally, we use the equilibrium-constant expression to calculate the equilibrium constant:

$$K_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]} = \frac{(1.87 \times 10^{-3})^2}{(0.065 \times 10^{-3})(1.065 \times 10^{-3})} = 51$$

Comment The same method can be applied to gaseous equilibrium problems to calculate K_p , in which case partial pressures are used as table entries in place of molar concentrations. Your instructor may refer to this kind of table as an ICE chart, where ICE stands for Initial – Change – Equilibrium.

PRACTICE EXERCISE

Sulfur trioxide decomposes at high temperature in a sealed container: $2 \text{SO}_3(\text{g}) \rightleftharpoons 2 \text{SO}_2(\text{g}) + \text{O}_2(\text{g})$. Initially, the vessel is charged at 1000 K with $\text{SO}_3(\text{g})$ at a partial pressure of 0.500 atm . At equilibrium the SO_3 partial pressure is 0.200 atm . Calculate the value of K_p at 1000 K .

Answer: 0.338

15.6 APPLICATIONS OF EQUILIBRIUM CONSTANTS

We have seen that the magnitude of K indicates the extent to which a reaction proceeds. If K is very large, the equilibrium mixture contains mostly substances on the product side of the equation for the reaction. (That is, the reaction proceeds far to the right.) If K is very small (that is, much less than 1), the equilibrium mixture contains mainly substances on the reactant side of the equation. The equilibrium constant also allows us to (1) predict the direction in which a reaction mixture achieves equilibrium and (2) calculate equilibrium concentrations of reactants and products.

Predicting the Direction of Reaction

For the formation of NH_3 from N_2 and H_2 (Equation 15.6), $K_c = 0.105$ at 472°C . Suppose we place 2.00 mol of H_2 , 1.00 mol of N_2 , and 2.00 mol of NH_3 in a 1.00-L container at 472°C . How will the mixture react to reach equilibrium? Will N_2 and H_2 react to form more NH_3 , or will NH_3 decompose to N_2 and H_2 ?

To answer this question, we substitute the starting concentrations of N_2 , H_2 , and NH_3 into the equilibrium-constant expression and compare its value to the equilibrium constant:

$$\frac{[\text{NH}_3]^2}{[\text{N}_2][\text{H}_2]^3} = \frac{(2.00)^2}{(1.00)(2.00)^3} = 0.500 \quad \text{whereas} \quad K_c = 0.105 \quad [15.22]$$

To reach equilibrium, the quotient $[\text{NH}_3]^2/[\text{N}_2][\text{H}_2]^3$ must decrease from the starting value of 0.500 to the equilibrium value of 0.105. Because the system is closed, this change can happen only if $[\text{NH}_3]$ decreases and $[\text{N}_2]$ and $[\text{H}_2]$ increase. Thus, the reaction proceeds toward equilibrium by forming N_2 and H_2 from NH_3 ; that is, the reaction as written in Equation 15.6 proceeds from right to left.

This approach can be formalized by defining a quantity called the reaction quotient. The **reaction quotient**, Q , is a number obtained by substituting reactant and product concentrations or partial pressures at any point during a reaction into an equilibrium-constant expression. Therefore, for the general reaction

the reaction quotient in terms of molar concentrations is

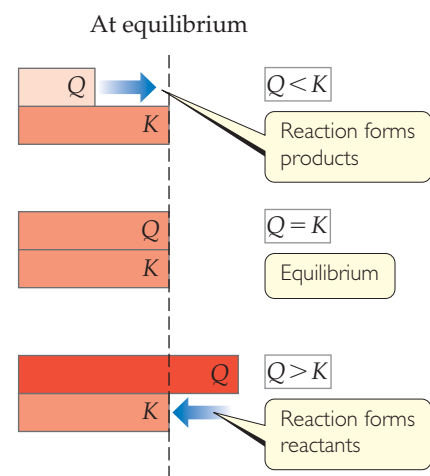

$$Q_c = \frac{[\text{D}]^d[\text{E}]^e}{[\text{A}]^a[\text{B}]^b} \quad [15.23]$$

(A related quantity Q_p can be written for any reaction that involves gases by using partial pressures instead of concentrations.)

Although we use what looks like the equilibrium-constant expression to calculate the reaction quotient, the concentrations we use may or may not be the equilibrium concentrations. For example, when we substituted the starting concentrations into the equilibrium-constant expression of Equation 15.22, we obtained $Q_c = 0.500$ whereas $K_c = 0.105$. The equilibrium constant has only one value at each temperature. The reaction quotient, however, varies as the reaction proceeds.

Of what use is Q ? One practical thing we can do with Q is tell whether our reaction really is at equilibrium, which is an especially valuable option when a reaction is very slow. We can take samples of our reaction mixture as the reaction proceeds, separate the components, and measure their concentrations. Then we insert these numbers into Equation 15.23 for our reaction. To determine whether or not we are at equilibrium, or in which direction the reaction proceeds to achieve equilibrium, we compare the values of Q_c and K_c or Q_p and K_p . Three possible situations arise:

- $Q = K$: The reaction quotient equals the equilibrium constant only if the system is at equilibrium.

▲ **FIGURE 15.8** Predicting the direction of a reaction by comparing Q and K at a given temperature.

- $Q > K$: The concentration of products is too large and that of reactants too small. Substances on the right side of the chemical equation react to form substances on the left; the reaction proceeds from right to left to approach equilibrium.
- $Q < K$: The concentration of products is too small and that of reactants too large. The reaction achieves equilibrium by forming more products; it proceeds from left to right.

These relationships are summarized in ◀ **FIGURE 15.8**.

SAMPLE EXERCISE 15.10 Predicting the Direction of Approach to Equilibrium

At 448 °C the equilibrium constant K_c for the reaction

is 50.5. Predict in which direction the reaction proceeds to reach equilibrium if we start with 2.0×10^{-2} mol of HI, 1.0×10^{-2} mol of H_2 , and 3.0×10^{-2} mol of I_2 in a 2.00-L container.

SOLUTION

Analyze We are given a volume and initial molar amounts of the species in a reaction and asked to determine in which direction the reaction must proceed to achieve equilibrium.

Plan We can determine the starting concentration of each species in the reaction mixture. We can then substitute the starting concentrations into the equilibrium-constant expression to calculate the reaction quotient, Q_c . Comparing the magnitudes of the equilibrium constant, which is given, and the reaction quotient will tell us in which direction the reaction will proceed.

Solve

The initial concentrations are

$$[\text{HI}] = 2.0 \times 10^{-2} \text{ mol}/2.00 \text{ L} = 1.0 \times 10^{-2} \text{ M}$$

$$[\text{H}_2] = 1.0 \times 10^{-2} \text{ mol}/2.00 \text{ L} = 5.0 \times 10^{-3} \text{ M}$$

$$[\text{I}_2] = 3.0 \times 10^{-2} \text{ mol}/2.00 \text{ L} = 1.5 \times 10^{-2} \text{ M}$$

The reaction quotient is therefore

$$Q_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]} = \frac{(1.0 \times 10^{-2})^2}{(5.0 \times 10^{-3})(1.5 \times 10^{-2})} = 1.3$$

Because $Q_c < K_c$, the concentration of HI must increase and the concentrations of H_2 and I_2 must decrease to reach equilibrium; the reaction as written proceeds left to right to attain equilibrium.

PRACTICE EXERCISE

At 1000 K the value of K_p for the reaction $2 \text{SO}_3(\text{g}) \rightleftharpoons 2 \text{SO}_2(\text{g}) + \text{O}_2(\text{g})$ is 0.338. Calculate the value for Q_p , and predict the direction in which the reaction proceeds toward equilibrium if the initial partial pressures are $P_{\text{SO}_3} = 0.16$ atm; $P_{\text{SO}_2} = 0.41$ atm; $P_{\text{O}_2} = 2.5$ atm.

Answer: $Q_p = 16$; $Q_p > K_p$, and so the reaction will proceed from right to left, forming more SO_3 .

Calculating Equilibrium Concentrations

Chemists frequently need to calculate the amounts of reactants and products present at equilibrium in a reaction for which they know the equilibrium constant. The approach in solving problems of this type is similar to the one we used for evaluating equilibrium constants: We tabulate initial concentrations or partial pressures, changes in those concentrations or pressures, and final equilibrium concentrations or partial pressures. Usually we end up using the equilibrium-constant expression to derive an equation that must be solved for an unknown quantity, as demonstrated in Sample Exercise 15.11.

SAMPLE EXERCISE 15.11 Calculating Equilibrium Concentrations

For the Haber process, $\text{N}_2(\text{g}) + 3 \text{H}_2(\text{g}) \rightleftharpoons 2 \text{NH}_3(\text{g})$, $K_p = 1.45 \times 10^{-5}$ at 500 °C. In an equilibrium mixture of the three gases at 500 °C, the partial pressure of H_2 is 0.928 atm and that of N_2 is 0.432 atm. What is the partial pressure of NH_3 in this equilibrium mixture?

SOLUTION

Analyze We are given an equilibrium constant, K_p , and the equilibrium partial pressures of two of the three substances in the equation (N_2 and H_2), and we are asked to calculate the equilibrium partial pressure for the third substance (NH_3).

Plan We can set K_p equal to the equilibrium-constant expression and substitute in the partial pressures that we know. Then we can solve for the only unknown in the equation.

Solve We tabulate the equilibrium pressures:

Because we do not know the equilibrium pressure of NH_3 , we represent it with x . At equilibrium the pressures must satisfy the equilibrium-constant expression:

$$K_p = \frac{(P_{\text{NH}_3})^2}{P_{\text{N}_2}(P_{\text{H}_2})^3} = \frac{x^2}{(0.432)(0.928)^3} = 1.45 \times 10^{-5}$$

We now rearrange the equation to solve for x :

$$x^2 = (1.45 \times 10^{-5})(0.432)(0.928)^3 = 5.01 \times 10^{-6}$$

$$x = \sqrt{5.01 \times 10^{-6}} = 2.24 \times 10^{-3} \text{ atm} = P_{\text{NH}_3}$$

Check We can always check our answer by using it to recalculate the value of the equilibrium constant:

$$K_p = \frac{(2.24 \times 10^{-3})^2}{(0.432)(0.928)^3} = 1.45 \times 10^{-5}$$

PRACTICE EXERCISE

At 500 K the reaction $\text{PCl}_5(\text{g}) \rightleftharpoons \text{PCl}_3(\text{g}) + \text{Cl}_2(\text{g})$ has $K_p = 0.497$. In an equilibrium mixture at 500 K, the partial pressure of PCl_5 is 0.860 atm and that of PCl_3 is 0.350 atm. What is the partial pressure of Cl_2 in the equilibrium mixture?

Answer: 1.22 atm

In many situations we know the value of the equilibrium constant and the initial amounts of all species. We must then solve for the equilibrium amounts. Solving this type of problem usually entails treating the change in concentration as a variable. The stoichiometry of the reaction gives us the relationship between the changes in the amounts of all the reactants and products, as illustrated in Sample Exercise 15.12. The calculations frequently involve the quadratic formula, as you will see in this exercise.

SAMPLE EXERCISE 15.12 Calculating Equilibrium Concentrations from Initial Concentrations

A 1.000-L flask is filled with 1.000 mol of $\text{H}_2(\text{g})$ and 2.000 mol of $\text{I}_2(\text{g})$ at 448 °C. The value of the equilibrium constant K_c for the reaction

at 448 °C is 50.5. What are the equilibrium concentrations of H_2 , I_2 , and HI in moles per liter?

SOLUTION

Analyze We are given the volume of a container, an equilibrium constant, and starting amounts of reactants in the container and are asked to calculate the equilibrium concentrations of all species.

Plan In this case we are not given any of the equilibrium concentrations. We must develop some relationships that relate the initial concentrations to those at equilibrium. The procedure is similar in many regards to that outlined in Sample Exercise 15.9, where we calculated an equilibrium constant using initial concentrations.

Solve First, we note the initial concentrations of H_2 and I_2 :

$$[\text{H}_2] = 1.000 \text{ M} \quad \text{and} \quad [\text{I}_2] = 2.000 \text{ M}$$

Second, we construct a table in which we tabulate the initial concentrations:

	$\text{H}_2(\text{g})$	+	$\text{I}_2(\text{g})$	\rightleftharpoons	$2 \text{HI}(\text{g})$
Initial concentration (M)	1.000		2.000		0
Change in concentration (M)					
Equilibrium concentration (M)					

Third, we use the stoichiometry of the reaction to determine the changes in concentration that occur as the reaction proceeds to equilibrium. The H_2 and I_2 concentrations will decrease as equilibrium is established and that of HI will increase. Let's represent the change in concentration of H_2 by x . The balanced chemical equation tells us the relationship between the changes in the concentrations of the three gases. For each x mol of H_2 that reacts, x mol of I_2 are consumed and $2x$ mol of HI are produced:

$$\text{H}_2(\text{g}) + \text{I}_2(\text{g}) \rightleftharpoons 2 \text{HI}(\text{g})$$

Initial concentration (M)	1.000	2.000	0
Change in concentration (M)	$-x$	$-x$	$+2x$
Equilibrium concentration (M)			

Fourth, we use initial concentrations and changes in concentrations, as dictated by stoichiometry, to express the equilibrium concentrations. With all our entries, our table now looks like this:

$$\text{H}_2(\text{g}) + \text{I}_2(\text{g}) \rightleftharpoons 2 \text{HI}(\text{g})$$

Initial concentration (M)	1.000	2.000	0
Change in concentration (M)	$-x$	$-x$	$+2x$
Equilibrium concentration (M)	$1.000 - x$	$2.000 - x$	$2x$

Fifth, we substitute the equilibrium concentrations into the equilibrium-constant expression and solve for x :

$$K_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]} = \frac{(2x)^2}{(1.000 - x)(2.000 - x)} = 50.5$$

If you have an equation-solving calculator, you can solve this equation directly for x . If not, expand this expression to obtain a quadratic equation in x :

$$4x^2 = 50.5(x^2 - 3.000x + 2.000)$$

$$46.5x^2 - 151.5x + 101.0 = 0$$

Solving the quadratic equation (Appendix A.3) leads to two solutions for x :

$$x = \frac{-(-151.5) \pm \sqrt{(-151.5)^2 - 4(46.5)(101.0)}}{2(46.5)} = 2.323 \text{ or } 0.935$$

When we substitute $x = 2.323$ into the expressions for the equilibrium concentrations, we find *negative* concentrations of H_2 and I_2 . Because a negative concentration is not chemically meaningful, we reject this solution. We then use $x = 0.935$ to find the equilibrium concentrations:

$$[\text{H}_2] = 1.000 - x = 0.065 \text{ M}$$

$$[\text{I}_2] = 2.000 - x = 1.065 \text{ M}$$

$$[\text{HI}] = 2x = 1.87 \text{ M}$$

Check We can check our solution by putting these numbers into the equilibrium-constant expression to assure that we correctly calculate the equilibrium constant:

$$K_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]} = \frac{(1.87)^2}{(0.065)(1.065)} = 51$$

Comment Whenever you use a quadratic equation to solve an equilibrium problem, one of the solutions to the equation will give you a value that leads to negative concentrations and thus is not chemically meaningful. Reject this solution to the quadratic equation.

PRACTICE EXERCISE

For the equilibrium $\text{PCl}_5(\text{g}) \rightleftharpoons \text{PCl}_3(\text{g}) + \text{Cl}_2(\text{g})$, the equilibrium constant K_p is 0.497 at 500 K. A gas cylinder at 500 K is charged with $\text{PCl}_5(\text{g})$ at an initial pressure of 1.66 atm. What are the equilibrium pressures of PCl_5 , PCl_3 , and Cl_2 at this temperature?

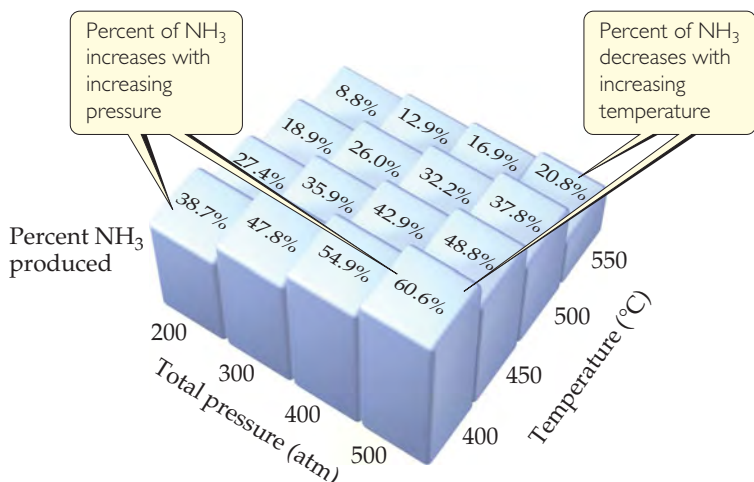

Answer: $P_{\text{PCl}_5} = 0.967 \text{ atm}$, $P_{\text{PCl}_3} = P_{\text{Cl}_2} = 0.693 \text{ atm}$

15.7 | LE CHÂTELIER'S PRINCIPLE

Many of the products we use in everyday life are obtained from the chemical industry. Chemists and chemical engineers in industry spend a great deal of time and effort to maximize the yield of valuable products and minimize waste. For example, when Haber developed his process for making ammonia from N_2 and H_2 , he examined how reaction conditions might be varied to increase yield. Using the values of the equilibrium constant at various temperatures, he calculated the equilibrium amounts of NH_3 formed under a variety of conditions. Some of Haber's results are shown in ► **FIGURE 15.9**.

GO FIGURE

At what combination of pressure and temperature should you run the reaction to maximize NH_3 yield?

◀ **FIGURE 15.9** Effect of temperature and pressure on NH_3 yield in the Haber process. Each mixture was produced by starting with a 3:1 molar mixture of H_2 and N_2 .

Notice that the percent of NH_3 present at equilibrium decreases with increasing temperature and increases with increasing pressure.

We can understand these effects in terms of a principle first put forward by Henri-Louis Le Châtelier* (1850–1936), a French industrial chemist: *If a system at equilibrium is disturbed by a change in temperature, pressure, or a component concentration, the system will shift its equilibrium position so as to counteract the effect of the disturbance.*

Le Châtelier's Principle

If a system at equilibrium is disturbed by a change in **concentration**, **pressure**, or **temperature**, the system will shift its equilibrium position so as to counter the effect of the disturbance.

Concentration: adding or removing a reactant or product

If a substance is added to a system at equilibrium, the system reacts to consume some of the substance. If a substance is removed from a system, the system reacts to produce more of substance.

**Pressure:** changing the pressure by changing the volume

At constant temperature, reducing the volume of a gaseous equilibrium mixture causes the system to shift in the direction that reduces the number of moles of gas.

**Temperature:**

If the temperature of a system at equilibrium is increased, the system reacts as if we added a reactant to an endothermic reaction or a product to an exothermic reaction. The equilibrium shifts in the direction that consumes the "excess reactant," namely heat.

*Pronounced "le-SHOT-lee-ay."

In this section we use Le Châtelier's principle to make qualitative predictions about how a system at equilibrium responds to various changes in external conditions. We consider three ways in which a chemical equilibrium can be disturbed: (1) adding or removing a reactant or product, (2) changing the pressure by changing the volume, and (3) changing the temperature.

Change in Reactant or Product Concentration

A system at dynamic equilibrium is in a state of balance. When the concentrations of species in the reaction are altered, the equilibrium shifts until a new state of balance is attained. What does *shift* mean? It means that reactant and product concentrations change over time to accommodate the new situation. *Shift* does *not* mean that the equilibrium constant itself is altered; the equilibrium constant remains the same. Le Châtelier's principle states that the shift is in the direction that minimizes or reduces the effect of the change. Therefore, *if a chemical system is already at equilibrium and the concentration of any substance in the mixture is increased (either reactant or product), the system reacts to consume some of that substance. Conversely, if the concentration of a substance is decreased, the system reacts to produce some of that substance.*

There is no change in the equilibrium constant when we change the concentrations of reactants or products. As an example, consider our familiar equilibrium mixture of N_2 , H_2 , and NH_3 :

Adding H_2 causes the system to shift so as to reduce the increased concentration of H_2 (▼ FIGURE 15.10). This change can occur only if the reaction consumes H_2 and simultaneously consumes N_2 to form more NH_3 . Adding N_2 to the equilibrium mixture likewise causes the reaction to shift toward forming more NH_3 . Removing NH_3 also causes a shift toward producing more NH_3 , whereas *adding* NH_3 to the system at equilibrium causes the reaction to shift in the direction that reduces the increased NH_3 concentration: Some of the added ammonia decomposes to form N_2 and H_2 .

In the Haber reaction, therefore, removing NH_3 from an equilibrium mixture of N_2 , H_2 , and NH_3 causes the reaction to shift right to form more NH_3 . If the NH_3 can be removed continuously as it is produced, the yield can be increased dramatically. In the

GO FIGURE

Why does the nitrogen concentration decrease after hydrogen is added?

► **FIGURE 15.10** Effect of adding H_2 to an equilibrium mixture of N_2 , H_2 , and NH_3 . Adding H_2 causes the reaction as written to shift to the right, consuming some H_2 to produce more NH_3 .

▲ FIGURE 15.11 Diagram of the industrial production of ammonia. Incoming $\text{N}_2(g)$ and $\text{H}_2(g)$ are heated to approximately $500\text{ }^\circ\text{C}$ and passed over a catalyst. When the resultant N_2 , H_2 , and NH_3 mixture is cooled, the NH_3 liquefies and is removed from the mixture, shifting the reaction to produce more NH_3 .

industrial production of ammonia, the NH_3 is continuously removed by selectively liquefying it (▲ FIGURE 15.11). (The boiling point of NH_3 , $-33\text{ }^\circ\text{C}$, is much higher than those of N_2 , $-196\text{ }^\circ\text{C}$, and H_2 , $-253\text{ }^\circ\text{C}$.) The liquid NH_3 is removed, and the N_2 and H_2 are recycled to form more NH_3 . As a result of the product being continuously removed, the reaction is driven essentially to completion.

▲ GIVE IT SOME THOUGHT

What happens to the equilibrium $2\text{NO}(g) + \text{O}_2(g) \rightleftharpoons 2\text{NO}_2(g)$ if

- O_2 is added to the system,
- NO is removed?

Effects of Volume and Pressure Changes

If a system containing one or more gases is at equilibrium and its volume is decreased, thereby increasing its total pressure, Le Châtelier's principle indicates that the system responds by shifting its equilibrium position to reduce the pressure. A system can reduce its pressure by reducing the total number of gas molecules (fewer molecules of gas exert a lower pressure). Thus, at constant temperature, *reducing the volume of a gaseous equilibrium mixture causes the system to shift in the direction that reduces the number of moles of gas*. Increasing the volume causes a shift in the direction that produces more gas molecules (► FIGURE 15.12).

▲ GIVE IT SOME THOUGHT

What happens to the equilibrium $2\text{SO}_2(g) + \text{O}_2(g) \rightleftharpoons 2\text{SO}_3(g)$ if the volume of the system is increased?

▲ **FIGURE 15.12** Pressure and Le Châtelier's principle.

In the reaction $N_2(g) + 3 H_2(g) \rightleftharpoons 2 NH_3(g)$, four molecules of reactant are consumed for every two molecules of product produced. Consequently, an increase in pressure (caused by a decrease in volume) shifts the reaction in the direction that produces fewer gas molecules, which leads to the formation of more NH_3 , as indicated in Figure 15.9. In the reaction $H_2(g) + I_2(g) \rightleftharpoons 2 HI(g)$, the number of molecules of gaseous products (two) equals the number of molecules of gaseous reactants; therefore, changing the pressure does not influence the position of equilibrium.

Keep in mind that, as long as temperature remains constant, pressure-volume changes do *not* change the value of K . Rather, these changes alter the partial pressures of the gaseous substances. In Sample Exercise 15.8, we calculated $K_p = 2.79 \times 10^{-5}$ for the Haber reaction, $N_2(g) + 3 H_2(g) \rightleftharpoons 2 NH_3(g)$, in an equilibrium mixture at $472^\circ C$ containing 7.38 atm H_2 , 2.46 atm N_2 , and 0.166 atm NH_3 . Consider what happens when we suddenly reduce the volume of the system by one-half. If there were no shift in equilibrium, this volume change would cause the partial pressures of all substances to double, giving $P_{H_2} = 14.76$ atm, $P_{N_2} = 4.92$ atm, and $P_{NH_3} = 0.332$ atm. The reaction quotient would then no longer equal the equilibrium constant:

$$Q_p = \frac{(P_{NH_3})^2}{P_{N_2}(P_{H_2})^3} = \frac{(0.332)^2}{(4.92)(14.76)^3} = 6.97 \times 10^{-6} \neq K_p$$

Because $Q_p < K_p$, the system would no longer be at equilibrium. Equilibrium would be reestablished by increasing P_{NH_3} and/or decreasing P_{N_2} and P_{H_2} until $Q_p = K_p = 2.79 \times 10^{-5}$. Therefore, the equilibrium shifts to the right in the reaction as written, as Le Châtelier's principle predicts.

It is possible to change the pressure of a system in which a chemical reaction is running without changing its volume. For example, pressure increases if additional amounts of any reacting components are added to the system. We have already seen how to deal with a change in concentration of a reactant or product. The total pressure in the reaction vessel might also be increased by adding a gas that is not involved in the equilibrium. For example, argon might be added to the ammonia equilibrium system. The argon would not alter the partial pressures of any of the reacting components and therefore would not cause a shift in equilibrium.

Effect of Temperature Changes

Changes in concentrations or partial pressures shift equilibria without changing the value of the equilibrium constant. In contrast, almost every equilibrium constant

changes as the temperature changes. For example, consider the equilibrium established when cobalt(II) chloride (CoCl_2) is dissolved in hydrochloric acid, $\text{HCl}(aq)$, in the endothermic reaction

Because $\text{Co}(\text{H}_2\text{O})_6^{2+}$ is pink and CoCl_4^{2-} is blue, the position of this equilibrium is readily apparent from the color of the solution (▼ FIGURE 15.13). When the solution is heated it turns blue, indicating that the equilibrium has shifted to form more CoCl_4^{2-} . Cooling the solution leads to a pink solution, indicating that the equilibrium has shifted to produce more $\text{Co}(\text{H}_2\text{O})_6^{2+}$. We can monitor this reaction by spectroscopic methods, measuring the concentration of all species at the different temperatures. ∞ (Section 14.2) We can then calculate the equilibrium constant at each temperature. How can we explain the fact that the equilibrium constants and therefore the position of equilibrium both depend on temperature?

We can deduce the rules for the relationship between K and temperature from Le Châtelier's principle. We do this by treating heat as a chemical reagent. In an *endothermic* (heat-absorbing) reaction, we consider heat a *reactant*, and in an *exothermic* (heat-releasing) reaction, we consider heat a *product*:

Endothermic: Reactants + heat \rightleftharpoons products

Exothermic: Reactants \rightleftharpoons products + heat

When the temperature of a system at equilibrium is increased, the system reacts as if we added a reactant to an endothermic reaction or a product to an exothermic reaction. The equilibrium shifts in the direction that consumes the excess reactant (or product), namely heat.

$\Delta H > 0$, endothermic reaction

At equilibrium, significant amounts of both pink $\text{Co}(\text{H}_2\text{O})_6^{2+}$ and blue CoCl_4^{2-} are present; solution appears violet

Add heat: reaction shifts right to increase blue CoCl_4^{2-} concentration and decrease pink $\text{Co}(\text{H}_2\text{O})_6^{2+}$ concentration

Remove heat: reaction shifts left to decrease blue CoCl_4^{2-} concentration and increase pink $\text{Co}(\text{H}_2\text{O})_6^{2+}$ concentration

◀ FIGURE 15.13 Temperature and Le Châtelier's principle.

GIVE IT SOME THOUGHT

Use Le Châtelier's principle to explain why the equilibrium vapor pressure of a liquid increases with increasing temperature.

In an endothermic reaction, such as Equation 15.24, heat is absorbed as reactants are converted to products. Thus, increasing the temperature causes the equilibrium to shift to the right, in the direction of making more products, and K increases. In an exothermic reaction, the opposite occurs: Heat is produced as reactants are converted to products. Thus, increasing the temperature in this case causes the equilibrium to shift to the left, in the direction of making more reactants, and K decreases.

Endothermic: Increasing T results in higher K value

Exothermic: Increasing T results in lower K value

Cooling a reaction has the opposite effect. As we lower the temperature, the equilibrium shifts in the direction that produces heat. Thus, cooling an endothermic reaction shifts the equilibrium to the left, decreasing K , as shown in Figure 15.13, and cooling an exothermic reaction shifts the equilibrium to the right, increasing K .

SAMPLE EXERCISE 15.13 Using Le Châtelier's Principle to Predict Shifts in Equilibrium

Consider the equilibrium

In which direction will the equilibrium shift when (a) N_2O_4 is added, (b) NO_2 is removed, (c) the pressure is increased by addition of $\text{N}_2(\text{g})$, (d) the volume is increased, (e) the temperature is decreased?

SOLUTION

Analyze We are given a series of changes to be made to a system at equilibrium and are asked to predict what effect each change will have on the position of the equilibrium.

Plan Le Châtelier's principle can be used to determine the effects of each of these changes.

Solve

(a) The system will adjust to decrease the concentration of the added N_2O_4 , so the equilibrium shifts to the right, in the direction of product.

(b) The system will adjust to the removal of NO_2 by shifting to the side that produces more NO_2 ; thus, the equilibrium shifts to the right.

(c) Adding N_2 will increase the total pressure of the system, but N_2 is not involved in the reaction. The partial pressures of NO_2 and N_2O_4 are therefore unchanged, and there is no shift in the position of the equilibrium.

(d) If the volume is increased, the system will shift in the direction that occupies a larger volume (more gas molecules); thus, the equilibrium shifts to the right.

(e) The reaction is endothermic, so we can imagine heat as a reagent on the reactant side of the equation. Decreasing the temperature will shift the equilibrium in the direction that produces heat, so the equilibrium shifts to the left, toward the formation of more N_2O_4 . Note that only this last change also affects the value of the equilibrium constant, K .

PRACTICE EXERCISE

For the reaction

in which direction will the equilibrium shift when (a) $\text{Cl}_2(\text{g})$ is removed, (b) the temperature is decreased, (c) the volume of the reaction system is increased, (d) $\text{PCl}_3(\text{g})$ is added?

Answers: (a) right, (b) left, (c) right, (d) left

SAMPLE EXERCISE 15.14 Predicting the Effect of Temperature on K

(a) Using the standard heat of formation data in Appendix C, determine the standard enthalpy change for the reaction

(b) Determine how the equilibrium constant for this reaction should change with temperature.

SOLUTION

Analyze We are asked to determine the standard enthalpy change of a reaction and how the equilibrium constant for the reaction varies with temperature.

Plan (a) We can use standard enthalpies of formation to calculate ΔH° for the reaction. (b) We can then use Le Châtelier's principle to determine what effect temperature will have on the equilibrium constant.

Solve

(a) Recall that the standard enthalpy change for a reaction is given by the sum of the standard molar enthalpies of formation of the products, each multiplied by its coefficient in the balanced chemical equation, less the same quantities for the reactants. ∞ (Section 5.7) At 25 °C, ΔH_f° for $\text{NH}_3(\text{g})$ is -46.19 kJ/mol . The ΔH_f° values for $\text{H}_2(\text{g})$ and $\text{N}_2(\text{g})$ are zero by definition because the enthalpies of formation of the elements in their normal states at 25 °C are defined as zero. ∞ (Section 5.7) Because 2 mol of NH_3 is formed, the total enthalpy change is

$$(2 \text{ mol})(-46.19 \text{ kJ/mol}) - 0 = -92.38 \text{ kJ}$$

(b) Because the reaction in the forward direction is exothermic, we can consider heat a product of the reaction. An increase in temperature causes the reaction to shift in the direction of less NH_3 and more N_2 and H_2 . This effect is seen in the values for K_p presented in **TABLE 15.2**. Notice that K_p changes markedly with changes in temperature and that it is larger at lower temperatures.

Comment The fact that K_p for the formation of NH_3 from N_2 and H_2 decreases with increasing temperature is a matter of great practical importance. To form NH_3 at a reasonable rate requires higher temperatures. At higher temperatures, however, the equilibrium constant is smaller, and so the percentage conversion to NH_3 is smaller. To compensate for this, higher pressures are needed because high pressure favors NH_3 formation.

PRACTICE EXERCISE

Using the thermodynamic data in Appendix C, determine the enthalpy change for the reaction

Use this result to determine how the equilibrium constant for the reaction should change with temperature.

Answer: $\Delta H^\circ = 508.3 \text{ kJ}$; the equilibrium constant will increase with increasing temperature

TABLE 15.2 • Variation in K_p with Temperature for $\text{N}_2 + 3 \text{H}_2 \rightleftharpoons 2 \text{NH}_3$

Temperature (°C)	K_p
300	4.34×10^{-3}
400	1.64×10^{-4}
450	4.51×10^{-5}
500	1.45×10^{-5}
550	5.38×10^{-6}
600	2.25×10^{-6}

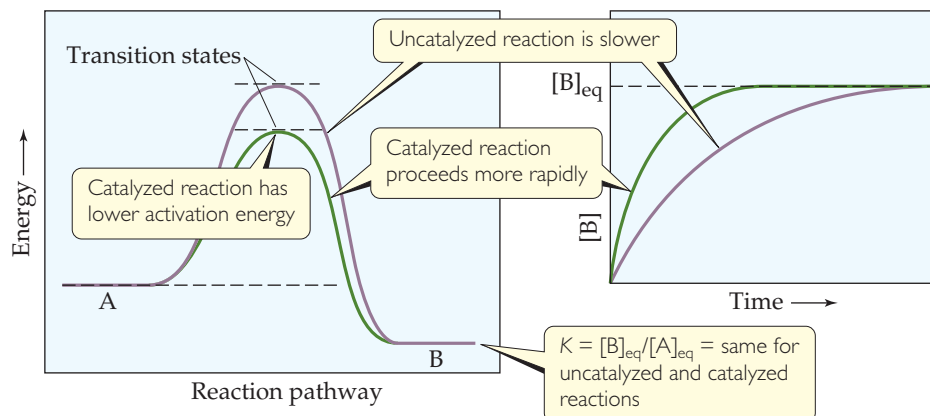

The Effect of Catalysts

What happens if we add a catalyst to a chemical system that is at equilibrium? As shown in **FIGURE 15.14**, ∞ (Figure 14.23) a catalyst lowers the activation barrier between reactants and products. The activation energies for both the forward and reverse reactions are lowered. The catalyst thereby increases the rates of both forward and reverse reactions. Since K is the ratio of the forward and reverse rate constants for a reaction, you can predict, correctly, that the presence of a catalyst, even though it changes the reaction *rate*, does not affect the numeric value of K (Figure 15.14). As a result, *a catalyst increases the rate at which equilibrium is achieved but does not change the composition of the equilibrium mixture.*

The rate at which a reaction approaches equilibrium is an important practical consideration. As an example, let's again consider the synthesis of ammonia from N_2 and H_2 . In designing his process, Haber had to deal with a rapid decrease in the equilibrium constant with increasing temperature (Table 15.2). At temperatures sufficiently high to

GO FIGURE

How much faster is the catalyzed reaction compared to the uncatalyzed reaction?

▲ FIGURE 15.14 A catalyst increases the rate at which equilibrium is reached but does not change the overall composition of the mixture at equilibrium.

give a satisfactory reaction rate, the amount of ammonia formed was too small. The solution to this dilemma was to develop a catalyst that would produce a reasonably rapid approach to equilibrium at a sufficiently low temperature, so that the equilibrium constant remained reasonably large. The development of a suitable catalyst thus became the focus of Haber's research efforts.

After trying different substances to see which would be most effective, Carl Bosch (see "Chemistry Put to Work: The Haber Process," page 615) settled on iron mixed with metal oxides, and variants of this catalyst formulation are still used today. These catalysts make it possible to obtain a reasonably rapid approach to equilibrium at around 400 to 500 °C and 200 to 600 atm. The high pressures are needed to obtain a satisfactory equilibrium amount of NH₃. If chemists and chemical engineers could identify a catalyst that leads to sufficiently rapid reaction at temperatures lower than 400 °C, it would be possible to obtain the same extent of equilibrium conversion at pressures much lower than 200 to 600 atm. This would result in great savings in the cost of the high-pressure equipment used in ammonia synthesis today.

As noted in Section 15.2, our need for nitrogen as fertilizer is growing globally, making the fixation of nitrogen a process of ever-increasing importance.

▲ GIVE IT SOME THOUGHT

Does the addition of a catalyst have any effect on the position of an equilibrium?

SAMPLE INTEGRATIVE EXERCISE Putting Concepts Together

At temperatures near 800 °C, steam passed over hot coke (a form of carbon obtained from coal) reacts to form CO and H₂:

The mixture of gases that results is an important industrial fuel called *water gas*. (a) At 800 °C the equilibrium constant for this reaction is $K_p = 14.1$. What are the equilibrium partial pressures of H₂O, CO, and H₂ in the equilibrium mixture at this temperature if we start with solid carbon and 0.100 mol of H₂O in a 1.00-L vessel? (b) What is the minimum amount of carbon required to achieve equilibrium under these conditions? (c) What is the total pressure in the vessel at equilibrium? (d) At 25 °C the value of K_p for this reaction is 1.7×10^{-21} . Is the reaction exothermic or endothermic? (e) To produce the maximum amount of CO and H₂ at equilibrium, should the pressure of the system be increased or decreased?

SOLUTION

(a) To determine the equilibrium partial pressures, we use the ideal-gas equation, first determining the starting partial pressure of hydrogen.

$$P_{\text{H}_2\text{O}} = \frac{n_{\text{H}_2\text{O}}RT}{V} = \frac{(0.100 \text{ mol})(0.08206 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(1073 \text{ K})}{1.00 \text{ L}} = 8.81 \text{ atm}$$

We then construct a table of initial partial pressures and their changes as equilibrium is achieved:

Initial partial pressure (atm)		8.81	0	0
Change in partial pressure (atm)		-x	+x	+x
Equilibrium partial pressure (atm)		8.81 - x	x	x

There are no entries in the table under C(s) because the reactant, being a solid, does not appear in the equilibrium-constant expression. Substituting the equilibrium partial pressures of the other species into the equilibrium-constant expression for the reaction gives

$$K_p = \frac{P_{\text{CO}}P_{\text{H}_2}}{P_{\text{H}_2\text{O}}} = \frac{(x)(x)}{(8.81 - x)} = 14.1$$

Multiplying through by the denominator gives a quadratic equation in x:

$$x^2 = (14.1)(8.81 - x)$$

$$x^2 + 14.1x - 124.22 = 0$$

Solving this equation for x using the quadratic formula yields $x = 6.14 \text{ atm}$. Hence, the equilibrium partial pressures are $P_{\text{CO}} = x = 6.14 \text{ atm}$, $P_{\text{H}_2} = x = 6.14 \text{ atm}$, and $P_{\text{H}_2\text{O}} = (8.81 - x) = 2.67 \text{ atm}$.

(b) Part (a) shows that $x = 6.14 \text{ atm}$ of H_2O must react for the system to achieve equilibrium. We can use the ideal-gas equation to convert this partial pressure into a mole amount.

$$n = \frac{PV}{RT} = \frac{(6.14 \text{ atm})(1.00 \text{ L})}{(0.08206 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(1073 \text{ K})} = 0.0697 \text{ mol}$$

Thus, 0.0697 mol of H_2O and the same amount of C must react to achieve equilibrium. As a result, there must be at least 0.0697 mol of C (0.836 g C) present among the reactants at the start of the reaction.

(c) The total pressure in the vessel at equilibrium is simply the sum of the equilibrium partial pressures:

$$P_{\text{total}} = P_{\text{H}_2\text{O}} + P_{\text{CO}} + P_{\text{H}_2} = 2.67 \text{ atm} + 6.14 \text{ atm} + 6.14 \text{ atm} = 14.95 \text{ atm}$$

(d) In discussing Le Châtelier's principle, we saw that endothermic reactions exhibit an increase in K_p with increasing temperature. Because the equilibrium constant for this reaction increases as temperature increases, the reaction must be endothermic. From the enthalpies of formation given in Appendix C, we can verify our prediction by calculating the enthalpy change for the reaction, $\Delta H^\circ = \Delta H_f^\circ(\text{CO}(g)) + \Delta H_f^\circ(\text{H}_2(g)) - \Delta H_f^\circ(\text{C}(s, \text{graphite})) - \Delta H_f^\circ(\text{H}_2\text{O}(g)) = +131.3 \text{ kJ}$. The positive sign for ΔH° indicates that the reaction is endothermic.

(e) According to Le Châtelier's principle, a decrease in the pressure causes a gaseous equilibrium to shift toward the side of the equation with the greater number of moles of gas. In this case there are two moles of gas on the product side and only one on the reactant side. Therefore, the pressure should be decreased to maximize the yield of the CO and H_2 .

CHEMISTRY PUT TO WORK

Controlling Nitric Oxide Emissions

The formation of NO from N₂ and O₂,

provides an interesting example of the practical importance of the fact that equilibrium constants and reaction rates change with temperature. By applying Le Châtelier's principle to this endothermic reaction and treating heat as a reactant, we deduce that an increase in temperature shifts the equilibrium in the direction of more NO. The equilibrium constant K_p for formation of 1 mol of NO from its elements at 300 K is only about 1×10^{-15} (► FIGURE 15.15). At 2400 K, however, the equilibrium constant is about 0.05, which is 10^{13} times larger than the 300 K value.

Figure 15.15 helps explain why NO is a pollution problem. In the cylinder of a modern high-compression automobile engine, the temperature during the fuel-burning part of the cycle is approximately 2400 K. Also, there is a fairly large excess of air in the cylinder. These conditions favor the formation of NO. After combustion, however, the gases cool quickly. As the temperature drops, the equilibrium in Equation 15.25 shifts to the left (because the reactant heat is being removed). The lower temperature also means that the reaction rate decreases, however, so the NO formed at 2400 K is essentially “frozen” in that form as the gas cools.

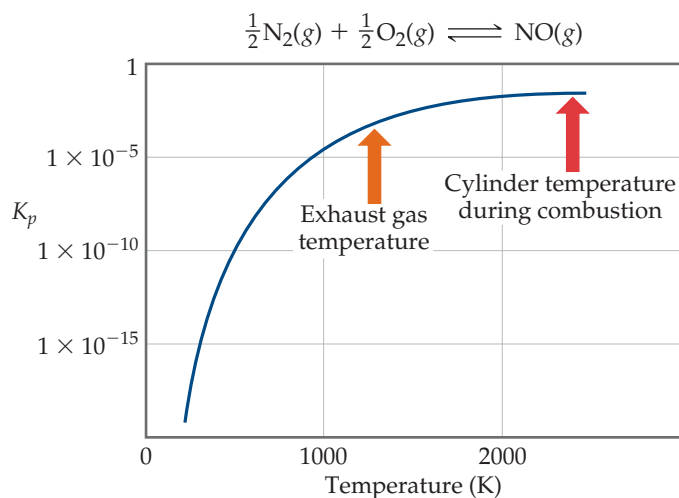

The gases exhausting from the cylinder are still quite hot, perhaps 1200 K. At this temperature, as shown in Figure 15.15, the equilibrium constant for formation of NO is about 5×10^{-4} , much smaller than the value at 2400 K. However, the rate of conversion of NO to N₂ and O₂ is too slow to permit much loss of NO before the gases are cooled further.

As discussed in the “Chemistry Put to Work” box in Section 14.7, one of the goals of automotive catalytic converters is to achieve rapid conversion of NO to N₂ and O₂ at the temperature of the

exhaust gas. Some catalysts developed for this reaction are reasonably effective under the grueling conditions in automotive exhaust systems. Nevertheless, scientists and engineers are continuously searching for new materials that provide even more effective catalysis of the decomposition of nitrogen oxides.

GO FIGURE

Estimate the value of K_p at 1200 K, the exhaust gas temperature.

▲ FIGURE 15.15 Equilibrium and temperature. The equilibrium constant increases with increasing temperature because the reaction is endothermic. It is necessary to use a log scale for K_p because the values vary over such a large range.

CHAPTER SUMMARY AND KEY TERMS

INTRODUCTION AND SECTION 15.1 A chemical reaction can achieve a state in which the forward and reverse processes are occurring at the same rate. This condition is called **chemical equilibrium**, and it results in the formation of an equilibrium mixture of the reactants and products of the reaction. The composition of an equilibrium mixture does not change with time if temperature is held constant.

SECTION 15.2 An equilibrium that is used throughout this chapter is the reaction $\text{N}_2(\text{g}) + 3\text{H}_2(\text{g}) \rightleftharpoons 2\text{NH}_3(\text{g})$. This reaction is the basis of the **Haber process** for the production of ammonia. The relationship between the concentrations of the reactants and products of a system at equilibrium is given by the **law of mass action**. For an

equilibrium equation of the form $aA + bB \rightleftharpoons dD + eE$, the **equilibrium-constant expression** is written as

$$K_c = \frac{[\text{D}]^d[\text{E}]^e}{[\text{A}]^a[\text{B}]^b}$$

where K_c is a constant called the **equilibrium constant**. When the equilibrium system of interest consists of gases, it is often convenient to express the concentrations of reactants and products in terms of gas pressures:

$$K_p = \frac{(P_D)^d(P_E)^e}{(P_A)^a(P_B)^b}$$

K_c and K_p are related by the expression $K_p = K_c(RT)^{\Delta n}$.

SECTION 15.3 The value of the equilibrium constant changes with temperature. A large value of K_c indicates that the equilibrium mixture contains more products than reactants and therefore lies toward the product side of the equation. A small value for the equilibrium constant means that the equilibrium mixture contains less products than reactants and therefore lies toward the reactant side. The equilibrium-constant expression and the equilibrium constant of the reverse of a reaction are the reciprocals of those of the forward reaction. If a reaction is the sum of two or more reactions, its equilibrium constant will be the product of the equilibrium constants for the individual reactions.

SECTION 15.4 Equilibria for which all substances are in the same phase are called **homogeneous equilibria**; in **heterogeneous equilibria** two or more phases are present. The concentrations of pure solids and liquids are left out of the equilibrium-constant expression for a heterogeneous equilibrium.

SECTION 15.5 If the concentrations of all species in an equilibrium are known, the equilibrium-constant expression can be used to calculate the equilibrium constant. The changes in the concentrations of reactants and products on the way to achieving equilibrium are governed by the stoichiometry of the reaction.

SECTION 15.6 The **reaction quotient**, Q , is found by substituting reactant and product concentrations or partial pressures at any point

during a reaction into the equilibrium-constant expression. If the system is at equilibrium, $Q = K$. If $Q \neq K$, however, the system is not at equilibrium. When $Q < K$, the reaction will move toward equilibrium by forming more products (the reaction proceeds from left to right); when $Q > K$, the reaction will proceed from right to left. Knowing the value of K makes it possible to calculate the equilibrium amounts of reactants and products, often by the solution of an equation in which the unknown is the change in a partial pressure or concentration.

SECTION 15.7 **Le Châtelier's principle** states that if a system at equilibrium is disturbed, the equilibrium will shift to minimize the disturbing influence. By this principle, if a reactant or product is added to a system at equilibrium, the equilibrium will shift to consume the added substance. The effects of removing reactants or products and of changing the pressure or volume of a reaction can be similarly deduced. For example, if the volume of the system is reduced, the equilibrium will shift in the direction that decreases the number of gas molecules. The enthalpy change for a reaction indicates how an increase in temperature affects the equilibrium: For an endothermic reaction, an increase in temperature shifts the equilibrium to the right; for an exothermic reaction, a temperature increase shifts the equilibrium to the left. Catalysts affect the speed at which equilibrium is reached but do not affect the magnitude of K .

KEY SKILLS

- Understand what is meant by chemical equilibrium and how it relates to reaction rates (Section 15.1).
- Write the equilibrium-constant expression for any reaction (Section 15.2).
- Relate K_c and K_p (Section 15.2).
- Relate the magnitude of an equilibrium constant to the relative amounts of reactants and products present in an equilibrium mixture (Section 15.3).
- Manipulate the equilibrium constant to reflect changes in the chemical equation (Section 15.3).
- Write the equilibrium-constant expression for a heterogeneous reaction (Section 15.4).
- Calculate an equilibrium constant from concentration measurements (Section 15.5).
- Predict the direction of a reaction given the equilibrium constant and the concentrations of reactants and products (Section 15.6).
- Calculate equilibrium concentrations given the equilibrium constant and all but one equilibrium concentration (Section 15.6).
- Calculate equilibrium concentrations, given the equilibrium constant and the starting concentrations (Section 15.6).
- Understand how changing the concentrations, volume, or temperature of a system at equilibrium affects the equilibrium position (Section 15.7).

KEY EQUATIONS

- $K_c = \frac{[D]^d[E]^e}{[A]^a[B]^b}$ [15.8] The equilibrium-constant expression for a general reaction of the type $a A + b B \rightleftharpoons d D + e E$; the concentrations are equilibrium concentrations only
- $K_p = \frac{(P_D)^d(P_E)^e}{(P_A)^a(P_B)^b}$ [15.11] The equilibrium-constant expression in terms of equilibrium partial pressures
- $K_p = K_c(RT)^{\Delta n}$ [15.14] Relating the equilibrium constant based on pressures to the equilibrium constant based on concentration
- $Q_c = \frac{[D]^d[E]^e}{[A]^a[B]^b}$ [15.23] The reaction quotient. The concentrations are for any time during a reaction. If the concentrations are equilibrium concentrations, then $Q_c = K_c$.

EXERCISES

VISUALIZING CONCEPTS

- 15.1 (a) Based on the following energy profile, predict whether $k_f > k_r$ or $k_f < k_r$. (b) Using Equation 15.5, predict whether the equilibrium constant for the process is greater than 1 or less than 1. [Section 15.1]

- 15.2 The following diagrams represent a hypothetical reaction $A \rightarrow B$, with A represented by red spheres and B represented by blue spheres. The sequence from left to right represents the system as time passes. Do the diagrams indicate that the system reaches an equilibrium state? Explain. [Sections 15.1 and 15.2]

- 15.3 The following diagram represents an equilibrium mixture produced for a reaction of the type $A + X \rightleftharpoons AX$. If the volume is 1 L, is K greater or smaller than 1? [Section 15.2]

- 15.4 The following diagram represents a reaction shown going to completion. (a) Letting A = red spheres and B = blue spheres, write a balanced equation for the reaction. (b) Write the equilibrium-constant expression for the reaction. (c) Assuming that all of the molecules are in the gas phase, calculate Δn , the change in the number of gas molecules that accompanies the reaction. (d) How can you calculate K_p if you know K_c at a particular temperature? [Section 15.2]

- 15.5 A friend says that the faster the reaction, the larger the equilibrium constant. Is your friend correct? Why or why not? [Sections 15.1 and 15.2]
- 15.6 A certain chemical reaction has $K_c = 1.5 \times 10^6$. Does this mean that at equilibrium there are 1.5×10^6 times as many product molecules as reactant molecules? Explain. [Sections 15.1 and 15.2]
- 15.7 Ethene (C_2H_4) reacts with halogens (X_2) by the following reaction:

The following figures represent the concentrations at equilibrium at the same temperature when X_2 is Cl_2 (green), Br_2 (brown), and I_2 (purple). List the equilibria from smallest to largest equilibrium constant. [Section 15.3]

(a)

(b)

(c)

- 15.8 The reaction $A_2 + B_2 \rightleftharpoons 2 AB$ has an equilibrium constant $K_c = 1.5$. The following diagrams represent reaction mixtures containing A_2 molecules (red), B_2 molecules (blue), and AB molecules. (a) Which reaction mixture is at equilibrium? (b) For those mixtures that are not at equilibrium, how will the reaction proceed to reach equilibrium? [Sections 15.5 and 15.6]

(i)

(ii)

(iii)

- 15.9 The reaction $A_2(g) + B(g) \rightleftharpoons A(g) + AB(g)$ has an equilibrium constant of $K_p = 2$. The accompanying diagram shows a mixture containing A atoms (red), A_2 molecules, and AB molecules (red and blue). How many B atoms should be added to the diagram to illustrate an equilibrium mixture? [Section 15.6]

- 15.10 The diagram shown here represents the equilibrium state for the reaction $A_2(g) + 2 B(g) \rightleftharpoons 2 AB(g)$. (a) Assuming the volume is 2 L, calculate the equilibrium constant K_c for the reaction. (b) If the volume of the equilibrium mixture is decreased, will the number of AB molecules increase or decrease? [Sections 15.5 and 15.7]

- 15.11 The following diagrams represent equilibrium mixtures for the reaction $A_2 + B \rightleftharpoons A + AB$ at (a) 300 K and (b) 500 K. The A atoms are red, and the B atoms are blue. Is the reaction exothermic or endothermic? [Section 15.7]

- 15.12 The following graph represents the yield of the compound AB at equilibrium in the reaction $A(g) + B(g) \rightarrow AB(g)$ at two different pressures, x and y , as a function of temperature.

- (a) Is this reaction exothermic or endothermic? (b) Is $P = x$ greater or smaller than $P = y$? [Section 15.7]

EQUILIBRIUM; THE EQUILIBRIUM CONSTANT (sections 15.1, 15.2, 15.3, 15.4)

- 15.13 Suppose that the gas-phase reactions $A \rightarrow B$ and $B \rightarrow A$ are both elementary processes with rate constants of $4.7 \times 10^{-3} \text{ s}^{-1}$ and $5.8 \times 10^{-1} \text{ s}^{-1}$, respectively. (a) What is the value of the equilibrium constant for the equilibrium $A(g) \rightleftharpoons B(g)$? (b) Which is greater at equilibrium, the partial pressure of A or the partial pressure of B? Explain.
- 15.14 Consider the reaction $A + B \rightleftharpoons C + D$. Assume that both the forward reaction and the reverse reaction are elementary processes and that the value of the equilibrium constant is very large. (a) Which species predominate at equilibrium, reactants or products? (b) Which reaction has the larger rate constant, the forward or the reverse? Explain.
- 15.15 Write the expression for K_c for the following reactions. In each case indicate whether the reaction is homogeneous or heterogeneous.
- $3 \text{ NO}(g) \rightleftharpoons \text{N}_2\text{O}(g) + \text{NO}_2(g)$
 - $\text{CH}_4(g) + 2 \text{ H}_2\text{S}(g) \rightleftharpoons \text{CS}_2(g) + 4 \text{ H}_2(g)$
 - $\text{Ni}(\text{CO})_4(g) \rightleftharpoons \text{Ni}(s) + 4 \text{ CO}(g)$
 - $\text{HF}(aq) \rightleftharpoons \text{H}^+(aq) + \text{F}^-(aq)$
 - $2 \text{ Ag}(s) + \text{Zn}^{2+}(aq) \rightleftharpoons 2 \text{ Ag}^+(aq) + \text{Zn}(s)$
 - $\text{H}_2\text{O}(l) \rightleftharpoons \text{H}^+(aq) + \text{OH}^-(aq)$
 - $2 \text{ H}_2\text{O}(l) \rightleftharpoons 2 \text{ H}^+(aq) + 2 \text{ OH}^-(aq)$
- 15.16 Write the expressions for K_c for the following reactions. In each case indicate whether the reaction is homogeneous or heterogeneous.
- $2 \text{ O}_3(g) \rightleftharpoons 3 \text{ O}_2(g)$
 - $\text{Ti}(s) + 2 \text{ Cl}_2(g) \rightleftharpoons \text{TiCl}_4(l)$
 - $2 \text{ C}_2\text{H}_4(g) + 2 \text{ H}_2\text{O}(g) \rightleftharpoons 2 \text{ C}_2\text{H}_6(g) + \text{O}_2(g)$
 - $\text{C}(s) + 2 \text{ H}_2(g) \rightleftharpoons \text{CH}_4(g)$
 - $4 \text{ HCl}(aq) + \text{O}_2(g) \rightleftharpoons 2 \text{ H}_2\text{O}(l) + 2 \text{ Cl}_2(g)$
 - $2 \text{ C}_8\text{H}_{18}(l) + 25 \text{ O}_2(g) \rightleftharpoons 16 \text{ CO}_2(g) + 18 \text{ H}_2\text{O}(g)$
 - $2 \text{ C}_8\text{H}_{18}(l) + 25 \text{ O}_2(g) \rightleftharpoons 16 \text{ CO}_2(g) + 18 \text{ H}_2\text{O}(l)$
- 15.17 When the following reactions come to equilibrium, does the equilibrium mixture contain mostly reactants or mostly products?
- $\text{N}_2(g) + \text{O}_2(g) \rightleftharpoons 2 \text{ NO}(g); K_c = 1.5 \times 10^{-10}$
 - $2 \text{ SO}_2(g) + \text{O}_2(g) \rightleftharpoons 2 \text{ SO}_3(g); K_p = 2.5 \times 10^9$

15.18 Which of the following reactions lies to the right, favoring the formation of products, and which lies to the left, favoring formation of reactants?

15.19 Can the equilibrium constant ever be a negative number? Explain.

15.20 Can the equilibrium constant ever be zero? Explain.

15.21 If $K_c = 0.042$ for $\text{PCl}_3(g) + \text{Cl}_2(g) \rightleftharpoons \text{PCl}_5(g)$ at 500 K, what is the value of K_p for this reaction at this temperature?

15.22 Calculate K_c at 303 K for $\text{SO}_2(g) + \text{Cl}_2(g) \rightleftharpoons \text{SO}_2\text{Cl}_2(g)$ if $K_p = 34.5$ at this temperature.

15.23 The equilibrium constant for the reaction

is $K_c = 1.3 \times 10^{-2}$ at 1000 K. (a) At this temperature does the equilibrium favor NO and Br_2 , or does it favor NOBr? (b) Calculate K_c for $2 \text{NOBr}(g) \rightleftharpoons 2 \text{NO}(g) + \text{Br}_2(g)$. (c) Calculate K_c for $\text{NOBr}(g) \rightarrow \text{NO}(g) + \frac{1}{2} \text{Br}_2(g)$.

15.24 Consider the following equilibrium:

(a) Calculate K_p . (b) Does the equilibrium mixture contain mostly H_2 and S_2 or mostly H_2S ? (c) Calculate the values of K_c and K_p if you rewrote the balanced chemical equation with 1 mol of $\text{H}_2(g)$ instead of 2 mol.

15.25 At 1000 K, $K_p = 1.85$ for the reaction

(a) What is the value of K_p for the reaction $\text{SO}_3(g) \rightleftharpoons \text{SO}_2(g) + \frac{1}{2} \text{O}_2(g)$? (b) What is the value of K_p for the reaction $2 \text{SO}_2(g) + \text{O}_2(g) \rightleftharpoons 2 \text{SO}_3(g)$? (c) What is the value of K_c for the reaction in part (b)?

15.26 Consider the following equilibrium, for which $K_p = 0.0752$ at 480°C :

(a) What is the value of K_p for the reaction $4 \text{HCl}(g) + \text{O}_2(g) \rightleftharpoons 2 \text{Cl}_2(g) + 2 \text{H}_2\text{O}(g)$? (b) What is the value of K_p for the reaction $\text{Cl}_2(g) + \text{H}_2\text{O}(g) \rightleftharpoons 2 \text{HCl}(g) + \frac{1}{2} \text{O}_2(g)$? (c) What is the value of K_c for the reaction in part (b)?

15.27 The following equilibria were attained at 823 K:

Based on these equilibria, calculate the equilibrium constant for $\text{H}_2(g) + \text{CO}_2(g) \rightleftharpoons \text{CO}(g) + \text{H}_2\text{O}(g)$ at 823 K.

15.28 Consider the equilibrium

Calculate the equilibrium constant K_p for this reaction, given the following information (at 298 K):

15.29 Explain why we normally exclude pure solids and liquids from equilibrium-constant expressions.

15.30 Explain why we normally exclude solvents from liquid-phase reactions in equilibrium-constant expressions.

15.31 Mercury(I) oxide decomposes into elemental mercury and elemental oxygen: $2 \text{Hg}_2\text{O}(s) \rightleftharpoons 4 \text{Hg}(l) + \text{O}_2(g)$. (a) Write the equilibrium-constant expression for this reaction in terms of partial pressures. (b) Suppose you run this reaction in a solvent that dissolves elemental mercury and elemental oxygen. Rewrite the equilibrium-constant expression in terms of molarities for the reaction, using (solv) to indicate solvation.

15.32 Consider the equilibrium $\text{Na}_2\text{O}(s) + \text{SO}_2(g) \rightleftharpoons \text{Na}_2\text{SO}_3(s)$. (a) Write the equilibrium-constant expression for this reaction in terms of partial pressures. (b) All the compounds in this reaction are soluble in water. Rewrite the equilibrium-constant expression in terms of molarities for the aqueous reaction.

CALCULATING EQUILIBRIUM CONSTANTS (section 15.5)

15.33 Methanol (CH_3OH) is produced commercially by the catalyzed reaction of carbon monoxide and hydrogen: $\text{CO}(g) + 2 \text{H}_2(g) \rightleftharpoons \text{CH}_3\text{OH}(g)$. An equilibrium mixture in a 2.00-L vessel is found to contain 0.0406 mol CH_3OH , 0.170 mol CO, and 0.302 mol H_2 at 500 K. Calculate K_c at this temperature.

15.34 Gaseous hydrogen iodide is placed in a closed container at 425°C , where it partially decomposes to hydrogen and iodine: $2 \text{HI}(g) \rightleftharpoons \text{H}_2(g) + \text{I}_2(g)$. At equilibrium it is found that $[\text{HI}] = 3.53 \times 10^{-3} \text{ M}$, $[\text{H}_2] = 4.79 \times 10^{-4} \text{ M}$, and $[\text{I}_2] = 4.79 \times 10^{-4} \text{ M}$. What is the value of K_c at this temperature?

15.35 The equilibrium $2 \text{NO}(g) + \text{Cl}_2(g) \rightleftharpoons 2 \text{NOCl}(g)$ is established at 500 K. An equilibrium mixture of the three gases has partial pressures of 0.095 atm, 0.171 atm, and 0.28 atm for NO, Cl_2 , and NOCl, respectively. (a) Calculate K_p for this reaction at 500.0 K. (b) If the vessel has a volume of 5.00 L, calculate K_c at this temperature.

15.36 Phosphorus trichloride gas and chlorine gas react to form phosphorus pentachloride gas: $\text{PCl}_3(g) + \text{Cl}_2(g) \rightleftharpoons \text{PCl}_5(g)$. A 7.5-L gas vessel is charged with a mixture of $\text{PCl}_3(g)$ and $\text{Cl}_2(g)$, which is allowed to equilibrate at 450 K. At equilibrium the partial pressures of the three gases are $P_{\text{PCl}_3} = 0.124 \text{ atm}$, $P_{\text{Cl}_2} = 0.157 \text{ atm}$, and $P_{\text{PCl}_5} = 1.30 \text{ atm}$. (a) What is the value of K_p at this temperature? (b) Does the equilibrium favor reactants or products? (c) Calculate K_c for this reaction at 450 K.

15.37 A mixture of 0.10 mol of NO, 0.050 mol of H_2 , and 0.10 mol of H_2O is placed in a 1.0-L vessel at 300 K. The following equilibrium is established:

At equilibrium $[\text{NO}] = 0.062 \text{ M}$. (a) Calculate the equilibrium concentrations of H_2 , N_2 , and H_2O . (b) Calculate K_c .

15.38 A mixture of 1.374 g of H_2 and 70.31 g of Br_2 is heated in a 2.00-L vessel at 700 K. These substances react according to

At equilibrium the vessel is found to contain 0.566 g of H_2 . (a) Calculate the equilibrium concentrations of H_2 , Br_2 , and HBr . (b) Calculate K_c .

- 15.39** A mixture of 0.2000 mol of CO_2 , 0.1000 mol of H_2 , and 0.1600 mol of H_2O is placed in a 2.000-L vessel. The following equilibrium is established at 500 K:

(a) Calculate the initial partial pressures of CO_2 , H_2 , and H_2O . (b) At equilibrium $P_{\text{H}_2\text{O}} = 3.51$ atm. Calculate the equilibrium partial pressures of CO_2 , H_2 , and CO . (c) Calculate K_p for the reaction. (d) Calculate K_c for the reaction.

- 15.40** A flask is charged with 1.500 atm of $\text{N}_2\text{O}_4(\text{g})$ and 1.00 atm $\text{NO}_2(\text{g})$ at 25 °C, and the following equilibrium is achieved:

After equilibrium is reached, the partial pressure of NO_2 is 0.512 atm. (a) What is the equilibrium partial pressure of N_2O_4 ? (b) Calculate the value of K_p for the reaction. (c) Calculate K_c for the reaction.

- 15.41** Two different proteins X and Y are dissolved in aqueous solution at 37 °C. The proteins bind in a 1:1 ratio to form XY. A

solution that is initially 1.00 mM in each protein is allowed to reach equilibrium. At equilibrium, 0.20 mM of free X and 0.20 mM of free Y remain. What is K_c for the reaction?

- [15.42]** A chemist at a pharmaceutical company is measuring equilibrium constants for reactions in which drug candidate molecules bind to a protein involved in cancer. The drug molecules bind the protein in a 1:1 ratio to form a drug-protein complex. The protein concentration in aqueous solution at 25 °C is 1.50×10^{-6} M. Drug A is introduced into the protein solution at an initial concentration of 2.00×10^{-6} M. Drug B is introduced into a separate, identical protein solution at an initial concentration of 2.00×10^{-6} M. At equilibrium, the drug A-protein solution has an A-protein complex concentration of 1.00×10^{-6} M, and the drug B solution has a B-protein complex concentration of 1.40×10^{-6} M. Calculate the K_c value for the A-protein binding reaction and for the B-protein binding reaction. Assuming that the drug that binds more strongly will be more effective, which drug is the better choice for further research?

APPLICATIONS OF EQUILIBRIUM CONSTANTS (section 15.6)

- 15.43** (a) How does a reaction quotient differ from an equilibrium constant? (b) If $Q_c < K_c$, in which direction will a reaction proceed in order to reach equilibrium? (c) What condition must be satisfied so that $Q_c = K_c$?

- 15.44** (a) How is a reaction quotient used to determine whether a system is at equilibrium? (b) If $Q_c > K_c$, how must the reaction proceed to reach equilibrium? (c) At the start of a certain reaction, only reactants are present; no products have been formed. What is the value of Q_c at this point in the reaction?

- 15.45** At 100 °C the equilibrium constant for the reaction $\text{COCl}_2(\text{g}) \rightleftharpoons \text{CO}(\text{g}) + \text{Cl}_2(\text{g})$ has the value $K_c = 2.19 \times 10^{-10}$. Are the following mixtures of COCl_2 , CO , and Cl_2 at 100 °C at equilibrium? If not, indicate the direction that the reaction must proceed to achieve equilibrium. (a) $[\text{COCl}_2] = 2.00 \times 10^{-3}$ M, $[\text{CO}] = 3.3 \times 10^{-6}$ M, $[\text{Cl}_2] = 6.62 \times 10^{-6}$ M; (b) $[\text{COCl}_2] = 4.50 \times 10^{-2}$ M, $[\text{CO}] = 1.1 \times 10^{-7}$ M, $[\text{Cl}_2] = 2.25 \times 10^{-6}$ M; (c) $[\text{COCl}_2] = 0.0100$ M, $[\text{CO}] = [\text{Cl}_2] = 1.48 \times 10^{-6}$ M

- 15.46** As shown in Table 15.2, K_p for the equilibrium

is 4.51×10^{-5} at 450 °C. For each of the mixtures listed here, indicate whether the mixture is at equilibrium at 450 °C. If it is not at equilibrium, indicate the direction (toward product or toward reactants) in which the mixture must shift to achieve equilibrium.

- (a) 98 atm NH_3 , 45 atm N_2 , 55 atm H_2
 (b) 57 atm NH_3 , 143 atm N_2 , no H_2
 (c) 13 atm NH_3 , 27 atm N_2 , 82 atm H_2

- 15.47** At 100 °C, $K_c = 0.078$ for the reaction

In an equilibrium mixture of the three gases, the concentrations of SO_2Cl_2 and SO_2 are 0.108 M and 0.052 M, respectively. What is the partial pressure of Cl_2 in the equilibrium mixture?

- 15.48** At 900 K the following reaction has $K_p = 0.345$:

In an equilibrium mixture the partial pressures of SO_2 and O_2 are 0.135 atm and 0.455 atm, respectively. What is the equilibrium partial pressure of SO_3 in the mixture?

- 15.49** (a) At 1285 °C the equilibrium constant for the reaction $\text{Br}_2(\text{g}) \rightleftharpoons 2 \text{Br}(\text{g})$ is $K_c = 1.04 \times 10^{-3}$. A 0.200-L vessel containing an equilibrium mixture of the gases has 0.245 g $\text{Br}_2(\text{g})$ in it. What is the mass of $\text{Br}(\text{g})$ in the vessel? (b) For the reaction $\text{H}_2(\text{g}) + \text{I}_2(\text{g}) \rightleftharpoons 2 \text{HI}(\text{g})$, $K_c = 55.3$ at 700 K. In a 2.00-L flask containing an equilibrium mixture of the three gases, there are 0.056 g H_2 and 4.36 g I_2 . What is the mass of HI in the flask?

- 15.50** (a) At 800 K the equilibrium constant for $\text{I}_2(\text{g}) \rightleftharpoons 2 \text{I}(\text{g})$ is $K_c = 3.1 \times 10^{-5}$. If an equilibrium mixture in a 10.0-L vessel contains 2.67×10^{-2} g of $\text{I}(\text{g})$, how many grams of I_2 are in the mixture? (b) For $2 \text{SO}_2(\text{g}) + \text{O}_2(\text{g}) \rightleftharpoons 2 \text{SO}_3(\text{g})$, $K_p = 3.0 \times 10^4$ at 700 K. In a 2.00-L vessel the equilibrium mixture contains 1.17 g of SO_3 and 0.105 g of O_2 . How many grams of SO_2 are in the vessel?

- 15.51** At 2000 °C the equilibrium constant for the reaction

is $K_c = 2.4 \times 10^3$. If the initial concentration of NO is 0.175 M, what are the equilibrium concentrations of NO , N_2 , and O_2 ?

- 15.52** For the equilibrium

at 400 K, $K_c = 7.0$. If 0.25 mol of Br_2 and 0.55 mol of Cl_2 are introduced into a 3.0-L container at 400 K, what will be the equilibrium concentrations of Br_2 , Cl_2 , and BrCl ?

- 15.53** At 373 K, $K_p = 0.416$ for the equilibrium

If the pressures of $\text{NOBr}(\text{g})$ and $\text{NO}(\text{g})$ are equal, what is the equilibrium pressure of $\text{Br}_2(\text{g})$?

- 15.54 At 218 °C, $K_c = 1.2 \times 10^{-4}$ for the equilibrium

Calculate the equilibrium concentrations of NH_3 and H_2S if a sample of solid NH_4SH is placed in a closed vessel at 218 °C and decomposes until equilibrium is reached.

- 15.55 Consider the reaction

At 25 °C the equilibrium constant is $K_c = 2.4 \times 10^{-5}$ for this reaction. (a) If excess $\text{CaSO}_4(s)$ is mixed with water at 25 °C to produce a saturated solution of CaSO_4 , what are the equilibrium concentrations of Ca^{2+} and SO_4^{2-} ? (b) If the resulting solution has a volume of 1.4 L, what is the minimum mass of $\text{CaSO}_4(s)$ needed to achieve equilibrium?

- 15.56 At 80 °C, $K_c = 1.87 \times 10^{-3}$ for the reaction

(a) Calculate the equilibrium concentrations of PH_3 and BCl_3 if a solid sample of PH_3BCl_3 is placed in a closed vessel at 80 °C and decomposes until equilibrium is reached. (b) If the flask has a volume of 0.250 L, what is the minimum mass of $\text{PH}_3\text{BCl}_3(s)$ that must be added to the flask to achieve equilibrium?

- 15.57 For the reaction $\text{I}_2 + \text{Br}_2(g) \rightleftharpoons 2\text{IBr}(g)$, $K_c = 280$ at 150 °C. Suppose that 0.500 mol IBr in a 2.00-L flask is allowed to reach equilibrium at 150 °C. What are the equilibrium concentrations of IBr , I_2 , and Br_2 ?

- 15.58 At 25 °C the reaction

has an equilibrium constant $K_c = 7.1 \times 10^{-4}$. What are the equilibrium concentrations of Ca^{2+} and CrO_4^{2-} in a saturated solution of CaCrO_4 ?

- 15.59 Methane, CH_4 , reacts with I_2 according to the reaction $\text{CH}_4(g) + \text{I}_2(g) \rightleftharpoons \text{CH}_3\text{I}(g) + \text{HI}(g)$. At 630 K, K_p for this reaction is 2.26×10^{-4} . A reaction was set up at 630 K with initial partial pressures of methane of 105.1 torr and of 7.96 torr for I_2 . Calculate the pressures, in torr, of all reactants and products at equilibrium.

- 15.60 The reaction of an organic acid with an alcohol, in organic solvent, to produce an ester and water is commonly done in the pharmaceutical industry. This reaction is catalyzed by strong acid (usually H_2SO_4). A simple example is the reaction of acetic acid with ethyl alcohol to produce ethyl acetate and water:

where “(solv)” indicates that all reactants and products are in solution but not an aqueous solution. The equilibrium constant for this reaction at 55 °C is 6.68. A pharmaceutical chemist makes up 15.0 L of a solution that is initially 0.275 M in acetic acid and 3.85 M in ethanol. At equilibrium, how many grams of ethyl acetate are formed?

LE CHÂTELIER'S PRINCIPLE (section 15.7)

- 15.61 Consider the following equilibrium for which $\Delta H < 0$

How will each of the following changes affect an equilibrium mixture of the three gases: (a) $\text{O}_2(g)$ is added to the system; (b) the reaction mixture is heated; (c) the volume of the reaction vessel is doubled; (d) a catalyst is added to the mixture; (e) the total pressure of the system is increased by adding a noble gas; (f) $\text{SO}_3(g)$ is removed from the system?

- 15.62 Consider $4\text{NH}_3(g) + 5\text{O}_2(g) \rightleftharpoons 4\text{NO}(g) + 6\text{H}_2\text{O}(g)$, $\Delta H = -904.4\text{ kJ}$. How does each of the following changes affect the yield of NO at equilibrium? Answer increase, decrease, or no change: (a) increase $[\text{NH}_3]$; (b) increase $[\text{H}_2\text{O}]$; (c) decrease $[\text{O}_2]$; (d) decrease the volume of the container in which the reaction occurs; (e) add a catalyst; (f) increase temperature.

- 15.63 How do the following changes affect the value of the equilibrium constant for a gas-phase exothermic reaction: (a) removal of a reactant (b) removal of a product, (c) decrease in the volume, (d) decrease in the temperature, (e) addition of a catalyst?

- 15.64 For a certain gas-phase reaction, the fraction of products in an equilibrium mixture is increased by either increasing the temperature or by increasing the volume of the reaction vessel. (a) Is the reaction exothermic or endothermic? (b) Does the balanced chemical equation have more molecules on the reactant side or product side?

- 15.65 Consider the following equilibrium between oxides of nitrogen

(a) Use data in Appendix C to calculate ΔH° for this reaction. (b) Will the equilibrium constant for the reaction increase or decrease with increasing temperature? Explain. (c) At constant temperature, would a change in the volume of the container affect the fraction of products in the equilibrium mixture?

- 15.66 Methanol (CH_3OH) can be made by the reaction of CO with H_2 :

(a) Use thermochemical data in Appendix C to calculate ΔH° for this reaction. (b) To maximize the equilibrium yield of methanol, would you use a high or low temperature? (c) To maximize the equilibrium yield of methanol, would you use a high or low pressure?

- 15.67 Ozone, O_3 , decomposes to molecular oxygen in the stratosphere according to the reaction $2\text{O}_3(g) \rightarrow 3\text{O}_2(g)$. Would an increase in pressure favor the formation of ozone or of oxygen?

- 15.68 *Bioremediation* is the use of microorganisms to degrade environmental pollutants. Many pollutants contain only carbon and hydrogen (oil being one example). The chemical reactions are complicated, but in general the microorganisms react the pollutant hydrocarbon with O_2 to produce CO_2 and other carbon-containing compounds that are incorporated into the organism's biomass. How would increasing levels of CO_2 in the environment affect the bioremediation reaction?

ADDITIONAL EXERCISES

- 15.69 Both the forward reaction and the reverse reaction in the following equilibrium are believed to be elementary steps:

At 25 °C the rate constants for the forward and reverse reactions are $1.4 \times 10^{-28} \text{ M}^{-1} \text{ s}^{-1}$ and $9.3 \times 10^{10} \text{ M}^{-1} \text{ s}^{-1}$, respectively. (a) What is the value for the equilibrium constant at 25 °C? (b) Are reactants or products more plentiful at equilibrium? (c) What additional information would you need in order to decide whether the reaction as written is endothermic or exothermic?

- 15.70 If $K_c = 1$ for the equilibrium $2 \text{ A}(g) \rightleftharpoons \text{B}(g)$, what is the relationship between $[\text{A}]$ and $[\text{B}]$ at equilibrium?

- 15.71 A mixture of CH_4 and H_2O is passed over a nickel catalyst at 1000 K. The emerging gas is collected in a 5.00-L flask and is found to contain 8.62 g of CO , 2.60 g of H_2 , 43.0 g of CH_4 , and 48.4 g of H_2O . Assuming that equilibrium has been reached, calculate K_c and K_p for the reaction.

- 15.72 When 2.00 mol of SO_2Cl_2 is placed in a 2.00-L flask at 303 K, 56% of the SO_2Cl_2 decomposes to SO_2 and Cl_2 :

(a) Calculate K_c for this reaction at this temperature. (b) Calculate K_p for this reaction at 303 K. (c) Repeat these calculations for 2.00 mol of SO_2Cl_2 in a 15.00-L vessel at 303 K.

- 15.73 A mixture of H_2 , S , and H_2S is held in a 1.0-L vessel at 90 °C and reacts according to the equation:

At equilibrium the mixture contains 0.46 g of H_2S and 0.40 g H_2 . (a) Write the equilibrium-constant expression for this reaction. (b) What is the value of K_c for the reaction at this temperature? (c) Why can we ignore the amount of S when doing the calculation in part (b)?

- 15.74 A sample of nitrosyl bromide (NOBr) decomposes according to the equation

An equilibrium mixture in a 5.00-L vessel at 100 °C contains 3.22 g of NOBr , 3.08 g of NO , and 4.19 g of Br_2 . (a) Calculate K_c . (b) What is the total pressure exerted by the mixture of gases? (c) What was the mass of the original sample of NOBr ?

- 15.75 Consider the hypothetical reaction $\text{A}(g) \rightleftharpoons 2 \text{ B}(g)$. A flask is charged with 0.75 atm of pure A , after which it is allowed to reach equilibrium at 0 °C. At equilibrium the partial pressure of A is 0.36 atm. (a) What is the total pressure in the flask at equilibrium? (b) What is the value of K_p ? (c) What could we do to maximize the yield of B ?

- 15.76 As shown in Table 15.2, the equilibrium constant for the reaction $\text{N}_2(g) + 3 \text{ H}_2(g) \rightleftharpoons 2 \text{ NH}_3(g)$ is $K_p = 4.34 \times 10^{-3}$ at 300 °C. Pure NH_3 is placed in a 1.00-L flask and allowed to reach equilibrium at this temperature. There are 1.05 g NH_3 in the equilibrium mixture. (a) What are the masses of N_2 and H_2 in the equilibrium mixture? (b) What was the initial mass of ammonia placed in the vessel? (c) What is the total pressure in the vessel?

- 15.77 For the equilibrium

$K_p = 8.5 \times 10^{-3}$ at 150 °C. If 0.025 atm of IBr is placed in a 2.0-L container, what is the partial pressure of all substances after equilibrium is reached?

- 15.78 For the equilibrium

$K_p = 0.052$ at 60 °C. (a) Calculate K_c . (b) After 3.00 g of solid PH_3BCl_3 is added to a closed 1.500-L vessel at 60 °C, the vessel is charged with 0.0500 g of $\text{BCl}_3(g)$. What is the equilibrium concentration of PH_3 ?

- [15.79] Solid NH_4SH is introduced into an evacuated flask at 24 °C. The following reaction takes place:

At equilibrium the total pressure (for NH_3 and H_2S taken together) is 0.614 atm. What is K_p for this equilibrium at 24 °C?

- [15.80] A 0.831-g sample of SO_3 is placed in a 1.00-L container and heated to 1100 K. The SO_3 decomposes to SO_2 and O_2 :

At equilibrium the total pressure in the container is 1.300 atm. Find the values of K_p and K_c for this reaction at 1100 K.

- 15.81 Nitric oxide (NO) reacts readily with chlorine gas as follows:

At 700 K the equilibrium constant K_p for this reaction is 0.26. Predict the behavior of each of the following mixtures at this temperature and indicate whether or not the mixtures are at equilibrium. If not, state whether the mixture will need to produce more products or reactants to reach equilibrium. (a) $P_{\text{NO}} = 0.15$ atm, $P_{\text{Cl}_2} = 0.31$ atm, and $P_{\text{NOCl}} = 0.11$ atm; (b) $P_{\text{NO}} = 0.12$ atm, $P_{\text{Cl}_2} = 0.10$ atm, and $P_{\text{NOCl}} = 0.050$ atm; (c) $P_{\text{NO}} = 0.15$ atm, $P_{\text{Cl}_2} = 0.20$ atm, and $P_{\text{NOCl}} = 5.10 \times 10^{-3}$ atm.

- 15.82 At 900 °C, $K_c = 0.0108$ for the reaction

A mixture of CaCO_3 , CaO , and CO_2 is placed in a 10.0-L vessel at 900 °C. For the following mixtures, will the amount of CaCO_3 increase, decrease, or remain the same as the system approaches equilibrium?

- (a) 15.0 g CaCO_3 , 15.0 g CaO , and 4.25 g CO_2
 (b) 2.50 g CaCO_3 , 25.0 g CaO , and 5.66 g CO_2
 (c) 30.5 g CaCO_3 , 25.5 g CaO , and 6.48 g CO_2

- 15.83 When 1.50 mol CO_2 and 1.50 mol H_2 are placed in a 3.00-L container at 395 °C, the following reaction occurs: $\text{CO}_2(g) + \text{H}_2(g) \rightleftharpoons \text{CO}(g) + \text{H}_2\text{O}(g)$. If $K_c = 0.802$, what are the concentrations of each substance in the equilibrium mixture?

- 15.84 The equilibrium constant K_c for $\text{C}(s) + \text{CO}_2(g) \rightleftharpoons 2 \text{ CO}(g)$ is 1.9 at 1000 K and 0.133 at 298 K. (a) If excess C is allowed to react with 25.0 g of CO_2 in a 3.00-L vessel at 1000 K, how many grams of CO are produced? (b) How many grams of C are consumed? (c) If a smaller vessel is used for the reaction, will the yield of CO be greater or smaller? (d) Is the reaction endothermic or exothermic?

- 15.85 NiO is to be reduced to nickel metal in an industrial process by use of the reaction

At 1600 K the equilibrium constant for the reaction is $K_p = 6.0 \times 10^2$. If a CO pressure of 150 torr is to be employed in the furnace and total pressure never exceeds 760 torr, will reduction occur?

- 15.86** Le Châtelier noted that many industrial processes of his time could be improved by an understanding of chemical equilibria. For example, the reaction of iron oxide with carbon monoxide was used to produce elemental iron and CO_2 according to the reaction

Even in Le Châtelier's time, it was noted that a great deal of CO was wasted, expelled through the chimneys over the furnaces. Le Châtelier wrote, "Because this incomplete reaction was thought to be due to an insufficiently prolonged contact between carbon monoxide and the iron ore [oxide], the dimensions of the furnaces have been increased. In England they have been made as high as thirty meters. But the proportion of carbon monoxide escaping has not diminished, thus demonstrating, by an experiment costing several hundred thousand francs, that the reduction of iron oxide by carbon monoxide is a limited reaction. Acquaintance with the laws of chemical equilibrium would have permitted the same conclusion to be reached more rapidly and far more economically." What does this anecdote tell us about the equilibrium constant for this reaction?

- [15.87]** At 700 K the equilibrium constant for the reaction

is $K_p = 0.76$. A flask is charged with 2.00 atm of CCl_4 , which then reaches equilibrium at 700 K. **(a)** What fraction of the CCl_4 is converted into C and Cl_2 ? **(b)** What are the partial pressures of CCl_4 and Cl_2 at equilibrium?

- [15.88]** The reaction $\text{PCl}_3(g) + \text{Cl}_2(g) \rightleftharpoons \text{PCl}_5(g)$ has $K_p = 0.0870$ at 300 °C. A flask is charged with 0.50 atm PCl_3 , 0.50 atm Cl_2 , and 0.20 atm PCl_5 at this temperature. **(a)** Use the reaction quotient to determine the direction the reaction must proceed to reach equilibrium. **(b)** Calculate the equilibrium partial pressures of the gases. **(c)** What effect will increasing the volume of the system have on the mole fraction of Cl_2 in the equilibrium mixture? **(d)** The reaction is exothermic. What effect will increasing the temperature of the system have on the mole fraction of Cl_2 in the equilibrium mixture?

- [15.89]** An equilibrium mixture of H_2 , I_2 , and HI at 458 °C contains 0.112 mol H_2 , 0.112 mol I_2 , and 0.775 mol HI in a 5.00-L

vessel. What are the equilibrium partial pressures when equilibrium is reestablished following the addition of 0.200 mol of HI?

- [15.90]** Consider the hypothetical reaction $\text{A}(g) + 2 \text{B}(g) \rightleftharpoons 2 \text{C}(g)$, for which $K_c = 0.25$ at a certain temperature. A 1.00-L reaction vessel is loaded with 1.00 mol of compound C, which is allowed to reach equilibrium. Let the variable x represent the number of mol/L of compound A present at equilibrium. **(a)** In terms of x , what are the equilibrium concentrations of compounds B and C? **(b)** What limits must be placed on the value of x so that all concentrations are positive? **(c)** By putting the equilibrium concentrations (in terms of x) into the equilibrium-constant expression, derive an equation that can be solved for x . **(d)** The equation from part (c) is a cubic equation (one that has the form $ax^3 + bx^2 + cx + d = 0$). In general, cubic equations cannot be solved in closed form. However, you can estimate the solution by plotting the cubic equation in the allowed range of x that you specified in part (b). The point at which the cubic equation crosses the x -axis is the solution. **(e)** From the plot in part (d), estimate the equilibrium concentrations of A, B, and C. (*Hint:* You can check the accuracy of your answer by substituting these concentrations into the equilibrium expression.)

- 15.91** At 1200 K, the approximate temperature of automobile exhaust gases (Figure 15.15), K_p for the reaction

is about 1×10^{-13} . Assuming that the exhaust gas (total pressure 1 atm) contains 0.2% CO, 12% CO_2 , and 3% O_2 by volume, is the system at equilibrium with respect to the CO_2 reaction? Based on your conclusion, would the CO concentration in the exhaust be decreased or increased by a catalyst that speeds up the CO_2 reaction?

- 15.92** Suppose that you worked at the U.S. Patent Office and a patent application came across your desk claiming that a newly developed catalyst was much superior to the Haber catalyst for ammonia synthesis because the catalyst led to much greater equilibrium conversion of N_2 and H_2 into NH_3 than the Haber catalyst under the same conditions. What would be your response?

INTEGRATIVE EXERCISES

- 15.93** Consider the reaction $\text{IO}_4^-(aq) + 2 \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_4\text{IO}_6^-(aq)$; $K_c = 3.5 \times 10^{-2}$. If you start with 25.0 mL of a 0.905 M solution of NaIO_4 , and then dilute it with water to 500.0 mL, what is the concentration of H_4IO_6^- at equilibrium?

- [15.94]** Silver chloride, $\text{AgCl}(s)$, is an "insoluble" strong electrolyte. **(a)** Write the equation for the dissolution of $\text{AgCl}(s)$ in $\text{H}_2\text{O}(l)$. **(b)** Write the expression for K_c for the reaction in part (a). **(c)** Based on the thermochemical data in Appendix C and Le Châtelier's principle, predict whether the solubility of AgCl in H_2O increases or decreases with increasing temperature. **(d)** The equilibrium constant for the dissolution of AgCl in water is 1.6×10^{-10} at 25 °C. In addition, $\text{Ag}^+(aq)$ can react with $\text{Cl}^-(aq)$ according to the reaction

where $K_c = 1.8 \times 10^5$ at 25 °C. Although AgCl is "not soluble" in water, the complex AgCl_2^- is soluble. At 25 °C, is the solubility of AgCl in a 0.100 M NaCl solution *greater* than the solubility of AgCl in pure water, due to the formation of soluble AgCl_2^- ions? Or is the AgCl solubility in 0.100 M NaCl *less* than in pure water because of a Le Châtelier-type argument? Justify your answer with calculations. (*Hint:* Any form in which silver is in solution counts as "solubility.")

- [15.95]** Consider the equilibrium $\text{A} \rightleftharpoons \text{B}$ in which both the forward and reverse reactions are elementary (single-step) reactions. Assume that the only effect of a catalyst on the reaction is to lower the activation energies of the forward and reverse reactions, as shown in Figure 15.14. Using the Arrhenius equation (Section 14.5), prove that the equilibrium constant is the same for the catalyzed reaction as for the uncatalyzed one.

- [15.96] The phase diagram for SO_2 is shown here. (a) What does this diagram tell you about the enthalpy change in the reaction $\text{SO}_2(l) \longrightarrow \text{SO}_2(g)$? (b) Calculate the equilibrium constant for this reaction at 100°C and at 0°C . (c) Why is it not possible to calculate an equilibrium constant between the gas and liquid phases in the supercritical region? (d) At which of the three points marked in red does $\text{SO}_2(g)$ most closely approach ideal-gas behavior? (e) At which of the three red points does $\text{SO}_2(g)$ behave least ideally?

- [15.97] Write the equilibrium-constant expression for the equilibrium

The table that follows shows the relative mole percentages of $\text{CO}_2(g)$ and $\text{CO}(g)$ at a total pressure of 1 atm for several temperatures. Calculate the value of K_p at each temperature. Is the reaction exothermic or endothermic? Explain.

Temperature ($^\circ\text{C}$)	CO_2 (mol %)	CO (mol %)
850	6.23	93.77
950	1.32	98.68
1050	0.37	99.63
1200	0.06	99.94

- 15.98 In Section 11.5 we defined the vapor pressure of a liquid in terms of an equilibrium. (a) Write the equation representing the equilibrium between liquid water and water vapor and the corresponding expression for K_p . (b) By using data in Appendix B, give the value of K_p for this reaction at 30°C . (c) What is the value of K_p for any liquid in equilibrium with its vapor at the normal boiling point of the liquid?
- 15.99 Water molecules in the atmosphere can form hydrogen-bonded dimers, $(\text{H}_2\text{O})_2$. The presence of these dimers is thought to be important in the nucleation of ice crystals in the atmosphere and in the formation of acid rain. (a) Using VSEPR theory, draw the structure of a water dimer, using dashed lines to indicate intermolecular interactions. (b) What kind of intermolecular forces are involved in water dimer formation? (c) The K_p for water dimer formation in the gas phase is 0.050 at 300 K and 0.020 at 350 K. Is water dimer formation endothermic or exothermic?
- 15.100 The protein hemoglobin (Hb) transports O_2 in mammalian blood. Each Hb can bind 4 O_2 molecules. The equilibrium constant for the O_2 -binding reaction is higher in fetal hemoglobin than in adult hemoglobin. In discussing protein oxygen-binding capacity, biochemists use a measure called the *P50 value*, defined as the partial pressure of oxygen at which 50% of the protein is saturated. Fetal hemoglobin has a *P50* value of 19 torr, and adult hemoglobin has a *P50* value of 26.8 torr. Use these data to estimate how much larger K_c is for the aqueous reaction $4 \text{O}_2(g) + \text{Hb}(aq) \longrightarrow [\text{Hb}(\text{O}_2)_4(aq)]$.

WHAT'S AHEAD

16.1 ACIDS AND BASES: A BRIEF REVIEW

We start by reviewing the *Arrhenius* definition of acids and bases.

16.2 BRØNSTED-LOWRY ACIDS AND BASES

We learn that a Brønsted-Lowry acid is a *proton donor* and a Brønsted-Lowry base is a *proton acceptor*. Two species that differ by the presence or absence of a proton are known as a *conjugate acid-base pair*.

16.3 THE AUTOIONIZATION OF WATER

We see that the *autoionization* of water produces small quantities of H_3O^+ and OH^- ions. The *equilibrium constant* for

autoionization, $K_w = [\text{H}_3\text{O}^+][\text{OH}^-]$, defines the relationship between H_3O^+ and OH^- concentrations in aqueous solutions.

16.4 THE pH SCALE

We use the pH scale to describe the acidity or basicity of an aqueous solution. Neutral solutions have a $\text{pH} = 7$, acidic solutions have pH below 7, and basic solutions have pH above 7.

16.5 STRONG ACIDS AND BASES

We categorize acids and bases as being either strong or weak electrolytes. *Strong* acids and bases are strong electrolytes, ionizing or dissociating completely in aqueous solution. *Weak* acids and bases are weak electrolytes and ionize only partially.

16

RHUBARB is a vegetable whose stalks are eaten for their tart flavor. The sour taste comes from the presence of acids in the plant.

16.6 WEAK ACIDS

We learn that the ionization of a weak acid in water is an equilibrium process with an equilibrium constant K_a that can be used to calculate the pH of a weak acid solution.

16.7 WEAK BASES

We learn that the ionization of a weak base in water is an equilibrium process with equilibrium constant K_b that can be used to calculate the pH of a weak base solution.

16.8 RELATIONSHIP BETWEEN K_a AND K_b

We see that the relationship $K_a \times K_b = K_w$ means that the stronger an acid, the weaker its conjugate base.

16.9 ACID–BASE PROPERTIES OF SALT SOLUTIONS

We explore the fact that the ions of a soluble ionic compound can serve as Brønsted–Lowry acids or bases.

16.10 ACID–BASE BEHAVIOR AND CHEMICAL STRUCTURE

We explore the relationship between chemical structure and acid–base behavior.

16.11 LEWIS ACIDS AND BASES

Finally, we learn that a Lewis acid is an *electron-pair acceptor* and a Lewis base is an *electron-pair donor*.

ACID–BASE EQUILIBRIA

TASTE IS ONE OF THE five senses we use to experience the world around us. Receptors on the tongue are sensitive to chemical stimuli that lead to five basic taste sensations: sweet, sour, salty, bitter, and umami (from the Japanese word for “delicious” and triggered by the amino acid glutamic acid). The sensation of

sour is a response to the presence of acids, and we associate a sour taste with certain fruits and vegetables because they contain acids. For example, lemons, limes, and grapefruits contain citric acid ($\text{H}_3\text{C}_6\text{H}_5\text{O}_7$), and green apples and grapes contain malic acid ($\text{H}_2\text{C}_4\text{H}_4\text{O}_5$). The vegetable rhubarb is among the sourest of foods, so sour that eating a fresh stalk of rhubarb is sure to elicit a pucker on the first bite. The sour taste comes from the high acid content of the stalks. One of several acids found in rhubarb is oxalic acid, ($\text{H}_2\text{C}_2\text{O}_4$) (► **FIGURE 16.1**), which in large doses can be lethal. The oxalic acid content in the leaves is much higher than in the stalks, so much so that the leaves are considered toxic.*

Acids and bases are important in numerous chemical processes that occur around us—from industrial processes to biological ones, from reactions in the laboratory to those in our environment. The time required for a metal object immersed in water to corrode, the ability of an aquatic environment to support fish and plant life, the fate of

*It is estimated that a 150-lb person would need to eat approximately 5 kg of rhubarb leaves to receive a lethal dose, although much smaller quantities would probably make you sick.

▲ FIGURE 16.1 Oxalic acid, $\text{H}_2\text{C}_2\text{O}_4$.

pollutants washed out of the air by rain, and even the rates of reactions that maintain our lives all critically depend on the acidity or basicity of solutions.

We have encountered acids and bases many times in earlier discussions. For example, a portion of Chapter 4 focused on their reactions. In this chapter we reexamine acids and bases, taking a closer look at how they are identified and characterized. In doing so, we consider their behavior both in terms of their structure and bonding and in terms of the chemical equilibria in which they participate.

16.1 ACIDS AND BASES: A BRIEF REVIEW

From the earliest days of experimental chemistry, scientists have recognized acids and bases by their characteristic properties. Acids have a sour taste and cause certain dyes to change color, whereas bases have a bitter taste and feel slippery (soap is a good example). Use of the term *base* comes from the old English meaning of the word, “to bring low.” (We still use the word *debase* in this sense, meaning to lower the value of something.) When a base is added to an acid, the base “lowers” the amount of acid. Indeed, when acids and bases are mixed in certain proportions, their characteristic properties disappear altogether. ∞ (Section 4.3)

By 1830 it was evident that all acids contain hydrogen but not all hydrogen-containing substances are acids. During the 1880s, the Swedish chemist Svante Arrhenius (1859–1927) defined acids as substances that produce H^+ ions in water and bases as substances that produce OH^- ions in water. Over time the Arrhenius concept of acids and bases came to be stated in the following way:

- An *acid* is a substance that, when dissolved in water, increases the concentration of H^+ ions.
- A *base* is a substance that, when dissolved in water, increases the concentration of OH^- ions.

Hydrogen chloride is an Arrhenius acid. Hydrogen chloride gas is highly soluble in water because of its chemical reaction with water, which produces hydrated H^+ and Cl^- ions:

The aqueous solution of HCl is known as hydrochloric acid. Concentrated hydrochloric acid is about 37% HCl by mass and is 12 M in HCl.

Sodium hydroxide is an Arrhenius base. Because NaOH is an ionic compound, it dissociates into Na^+ and OH^- ions when it dissolves in water, thereby releasing OH^- ions into the solution.

▲ GIVE IT SOME THOUGHT

What two ions are central to the Arrhenius definitions of acids and bases?

16.2 BRØNSTED–LOWRY ACIDS AND BASES

The Arrhenius concept of acids and bases, while useful, has limitations. For one thing, it is restricted to aqueous solutions. In 1923 the Danish chemist Johannes Brønsted (1879–1947) and the English chemist Thomas Lowry (1874–1936) independently proposed a more general definition of acids and bases. Their concept is based on the fact that *acid–base reactions involve the transfer of H^+ ions from one substance to another.*

The H^+ Ion in Water

We might at first imagine that ionization of HCl in water produces just H^+ and Cl^- . A hydrogen ion is no more than a bare proton, however, and would interact strongly with

any source of electron density, such as the nonbonding electron pairs on the oxygen atoms of water molecules. For example, the interaction of a proton with water forms the **hydronium ion**, $\text{H}_3\text{O}^+(\text{aq})$:

The behavior of H^+ ions in liquid water is complex because hydronium ions are not the only polyatomic ions that form when H^+ interacts with water molecules. The H_3O^+ ion can form hydrogen bonds to additional H_2O molecules to generate such ions as H_5O_2^+ and H_9O_4^+ (► **FIGURE 16.2**)

Chemists use the notations $\text{H}^+(\text{aq})$ and $\text{H}_3\text{O}^+(\text{aq})$ interchangeably to represent the hydrated proton responsible for the characteristic properties of aqueous solutions of acids. We often use the notation $\text{H}^+(\text{aq})$ for simplicity and convenience, as we did in Chapter 4 and Equation 16.1. The notation $\text{H}_3\text{O}^+(\text{aq})$, however, more closely represents reality.

Proton-Transfer Reactions

In the reaction that occurs when HCl dissolves in water, the HCl molecule transfers an H^+ ion (a proton) to a water molecule. Thus, we can represent the reaction as occurring between an HCl molecule and a water molecule to form hydronium and chloride ions:

The polar H_2O molecule promotes the ionization of acids in water solution by accepting a proton to form H_3O^+ .

Brønsted and Lowry proposed definitions of acids and bases in terms of their ability to transfer protons:

- An *acid* is a substance (molecule or ion) that donates a proton to another substance.
- A *base* is a substance that accepts a proton.

Thus, when HCl dissolves in water (Equation 16.3), HCl acts as a **Brønsted–Lowry acid** (it donates a proton to H_2O), and H_2O acts as a **Brønsted–Lowry base** (it accepts a proton from HCl).

Because the emphasis in the Brønsted–Lowry concept is on proton transfer, the concept also applies to reactions that do not occur in aqueous solution. In the reaction

GO FIGURE
Which type of intermolecular force do the dotted lines in this figure represent?

▲ **FIGURE 16.2** Ball-and-stick models and Lewis structures for two hydrated hydronium ions.

between gas phase HCl and NH₃, for example, a proton is transferred from the acid HCl to the base NH₃:

The hazy film that forms on the windows of general chemistry laboratories and on glassware in the laboratory is largely solid NH₄Cl formed by the gas-phase reaction between HCl and NH₃.

Let's consider another example that compares the relationship between the Arrhenius and Brønsted–Lowry definitions of acids and bases—an aqueous solution of ammonia, in which we have the equilibrium:

Ammonia is a Brønsted–Lowry base because it accepts a proton from H₂O. Ammonia is also an Arrhenius base because adding it to water leads to an increase in the concentration of OH[−](aq).

An acid and a base always work together to transfer a proton. In other words, a substance can function as an acid only if another substance simultaneously behaves as a base. To be a Brønsted–Lowry acid, a molecule or ion must have a hydrogen atom it can lose as an H⁺ ion. To be a Brønsted–Lowry base, a molecule or ion must have a non-bonding pair of electrons it can use to bind the H⁺ ion.

Some substances can act as an acid in one reaction and as a base in another. For example, H₂O is a Brønsted–Lowry base in Equation 16.3 and a Brønsted–Lowry acid in Equation 16.5. A substance capable of acting as either an acid or a base is called **amphiprotic**. An amphiprotic substance acts as a base when combined with something more strongly acidic than itself and as an acid when combined with something more strongly basic than itself.

GIVE IT SOME THOUGHT

In the forward reaction of this equilibrium, which substance acts as the Brønsted–Lowry base?

Conjugate Acid–Base Pairs

In any acid–base equilibrium, both the forward reaction (to the right) and the reverse reaction (to the left) involve proton transfer. For example, consider the reaction of an acid HX with water:

In the forward reaction, HX donates a proton to H₂O. Therefore, HX is the Brønsted–Lowry acid and H₂O is the Brønsted–Lowry base. In the reverse reaction, the H₃O⁺ ion donates a proton to the X[−] ion, so H₃O⁺ is the acid and X[−] is the base. When the acid HX donates a proton, it leaves behind a substance, X[−], that can act as a base. Likewise, when H₂O acts as a base, it generates H₃O⁺, which can act as an acid.

An acid and a base such as HX and X^- that differ only in the presence or absence of a proton are called a **conjugate acid–base pair**.^{*} Every acid has a **conjugate base**, formed by removing a proton from the acid. For example, OH^- is the conjugate base of H_2O , and X^- is the conjugate base of HX . Every base has a **conjugate acid**, formed by adding a proton to the base. Thus, H_3O^+ is the conjugate acid of H_2O , and HX is the conjugate acid of X^- .

In any acid–base (proton-transfer) reaction, we can identify two sets of conjugate acid–base pairs. For example, consider the reaction between nitrous acid and water:

Likewise, for the reaction between NH_3 and H_2O (Equation 16.5), we have

SAMPLE EXERCISE 16.1 Identifying Conjugate Acids and Bases

(a) What is the conjugate base of HClO_4 , H_2S , PH_4^+ , HCO_3^- ? (b) What is the conjugate acid of CN^- , SO_4^{2-} , H_2O , HCO_3^- ?

SOLUTION

Analyze We are asked to give the conjugate base for several acids and the conjugate acid for several bases.

Plan The conjugate base of a substance is simply the parent substance minus one proton, and the conjugate acid of a substance is the parent substance plus one proton.

Solve

(a) HClO_4 less one proton H^+ is ClO_4^- . The other conjugate bases are HS^- , PH_3 , and CO_3^{2-} .

(b) CN^- plus one proton H^+ is HCN . The other conjugate acids are HSO_4^- , H_3O^+ , and H_2CO_3 . Notice that the hydrogen carbonate ion (HCO_3^-) is amphiprotic. It can act as either an acid or a base.

PRACTICE EXERCISE

Write the formula for the conjugate acid of each of the following: HSO_3^- , F^- , PO_4^{3-} , CO .

Answers: H_2SO_3 , HF , HPO_4^{2-} , HCO^+

Once you become proficient at identifying conjugate acid–base pairs it is not difficult to write equations for reactions involving Brønsted–Lowry acids and bases (proton-transfer reactions).

^{*}The word *conjugate* means “joined together as a pair.”

SAMPLE EXERCISE 16.2 Writing Equations for Proton-Transfer Reactions

The hydrogen sulfite ion (HSO_3^-) is amphiprotic. Write an equation for the reaction of HSO_3^- with water (a) in which the ion acts as an acid and (b) in which the ion acts as a base. In both cases identify the conjugate acid–base pairs.

SOLUTION

Analyze and Plan We are asked to write two equations representing reactions between HSO_3^- and water, one in which HSO_3^- should donate a proton to water, thereby acting as a Brønsted–Lowry acid, and one in which HSO_3^- should accept a proton from water, thereby acting as a base. We are also asked to identify the conjugate pairs in each equation.

Solve

The conjugate pairs in this equation are HSO_3^- (acid) and SO_3^{2-} (conjugate base), and H_2O (base) and H_3O^+ (conjugate acid).

The conjugate pairs in this equation are H_2O (acid) and OH^- (conjugate base), and HSO_3^- (base) and H_2SO_3 (conjugate acid).

PRACTICE EXERCISE

When lithium oxide (Li_2O) is dissolved in water, the solution turns basic from the reaction of the oxide ion (O^{2-}) with water. Write the equation for this reaction and identify the conjugate acid–base pairs.

Answer: $\text{O}^{2-}(aq) + \text{H}_2\text{O}(l) \longrightarrow \text{OH}^-(aq) + \text{OH}^-(aq)$. The OH^- is both the conjugate acid of O^{2-} and the conjugate base of H_2O .

Relative Strengths of Acids and Bases

Some acids are better proton donors than others, and some bases are better proton acceptors than others. If we arrange acids in order of their ability to donate a proton, we find that the more easily a substance gives up a proton, the less easily its conjugate base accepts a proton. Similarly, the more easily a base accepts a proton, the less easily its conjugate acid gives up a proton. In other words, *the stronger an acid, the weaker its conjugate base*, and *the stronger a base, the weaker its conjugate acid*. Thus, if we know something about the strength of an acid (its ability to donate protons), we also know something about the strength of its conjugate base (its ability to accept protons).

The inverse relationship between the strengths of acids and their conjugate bases is illustrated in ► **FIGURE 16.3**. Here we have grouped acids and bases into three broad categories based on their behavior in water:

1. A *strong acid* completely transfers its protons to water, leaving no undissociated molecules in solution. ∞ (Section 4.3) Its conjugate base has a negligible tendency to be protonated (to accept protons) in aqueous solution. (*The conjugate base of a strong acid shows negligible basicity.*)
2. A *weak acid* only partially dissociates in aqueous solution and therefore exists in the solution as a mixture of the acid and its conjugate base. The conjugate base of a weak acid shows a slight ability to remove protons from water. (*The conjugate base of a weak acid is a weak base.*)
3. A substance with *negligible acidity* contains hydrogen but does not demonstrate any acidic behavior in water. Its conjugate base is a strong base, reacting completely with water, abstracting protons to form OH^- ions. (*The conjugate base of a substance with negligible acidity is a strong base.*)

The ions $\text{H}^+(aq)$ and $\text{OH}^-(aq)$ are, respectively, the strongest possible acid and strongest possible base that can exist at equilibrium in aqueous solution. Stronger acids react with water to produce $\text{H}^+(aq)$ ions, and stronger bases react with water to produce $\text{OH}^-(aq)$ ions. This effect is known as the *leveling effect*.

GO FIGURE

If O^{2-} ions are added to water, what reaction, if any, occurs?

▲ FIGURE 16.3 Relative strengths of select conjugate acid–base pairs. The two members of each pair are listed opposite each other in the two columns.

GIVE IT SOME THOUGHT

Given that HClO_4 is a strong acid, how would you classify the basicity of ClO_4^- ?

We can think of proton-transfer reactions as being governed by the relative abilities of two bases to abstract protons. For example, consider the proton transfer that occurs when an acid HX dissolves in water:

If H_2O (the base in the forward reaction) is a stronger base than X^- (the conjugate base of HX), H_2O abstracts the proton from HX to produce H_3O^+ and X^- . As a result, the equilibrium lies to the right. This describes the behavior of a strong acid in water. For example, when HCl dissolves in water, the solution consists almost entirely of H_3O^+ and Cl^- ions with a negligible concentration of HCl molecules:

H_2O is a stronger base than Cl^- (Figure 16.3), so H_2O acquires the proton to become the hydronium ion.

When X^- is a stronger base than H_2O , the equilibrium lies to the left. This situation occurs when HX is a weak acid. For example, an aqueous solution of acetic acid consists mainly of CH_3COOH molecules with only a relatively few H_3O^+ and CH_3COO^- ions:

The CH_3COO^- ion is a stronger base than H_2O (Figure 16.3) and therefore abstracts the proton from H_3O^+ .

From these examples, we conclude that *in every acid–base reaction, equilibrium favors transfer of the proton from the stronger acid to the stronger base to form the weaker acid and the weaker base.*

SAMPLE EXERCISE 16.3 Predicting the Position of a Proton-Transfer Equilibrium

For the following proton-transfer reaction use Figure 16.3 to predict whether the equilibrium lies to the left ($K_c < 1$) or to the right ($K_c > 1$):

**SOLUTION**

Analyze We are asked to predict whether an equilibrium lies to the right, favoring products, or to the left, favoring reactants.

Plan This is a proton-transfer reaction, and the position of the equilibrium will favor the proton going to the stronger of two bases. The two bases in the equation are CO_3^{2-} , the base in the forward reaction, and SO_4^{2-} , the conjugate base of HSO_4^- . We can find the relative positions of these two bases in Figure 16.3 to determine which is the stronger base.

Solve The CO_3^{2-} ion appears lower in the right-hand column in Figure 16.3 and is therefore a stronger base than SO_4^{2-} . CO_3^{2-} , therefore, will get the proton preferentially to become HCO_3^- , while SO_4^{2-} will remain mostly unprotonated. The resulting equilibrium lies to the right, favoring products (that is, $K_c > 1$):

Comment Of the two acids HSO_4^- and HCO_3^- , the stronger one (HSO_4^-) gives up a proton more readily, and the weaker one (HCO_3^-) tends to retain its proton. Thus, the equilibrium favors the direction in which the proton moves from the stronger acid and becomes bonded to the stronger base.

PRACTICE EXERCISE

For each reaction, use Figure 16.3 to predict whether the equilibrium lies to the left or to the right:

Answers: (a) left, (b) right

16.3 THE AUTOIONIZATION OF WATER

One of the most important chemical properties of water is its ability to act as either a Brønsted-Lowry acid or a Brønsted-Lowry base. In the presence of an acid, it acts as a proton acceptor; in the presence of a base, it acts as a proton donor. In fact, one water molecule can donate a proton to another water molecule:

We call this process the **autoionization** of water.

Because the forward and reverse reactions in Equation 16.12 are extremely rapid no water molecule remains ionized for long. At room temperature only about two out of every 10^9 water molecules are ionized at any given instant. Thus, pure water consists almost entirely of H_2O molecules and is an extremely poor conductor of electricity. Nevertheless, the autoionization of water is very important, as we will soon see.

▲ FIGURE 16.4 Relative concentrations of H^+ and OH^- in aqueous solutions at 25 °C.

The Ion Product of Water

The equilibrium-constant expression for the autoionization of water is

$$K_c = [\text{H}_3\text{O}^+][\text{OH}^-] \quad [16.13]$$

The term $[\text{H}_2\text{O}]$ is excluded from the equilibrium-constant expression because we exclude the concentrations of pure solids and liquids. ∞ (Section 15.4) Because this expression refers specifically to the autoionization of water, we use the symbol K_w to denote the equilibrium constant, which we call the **ion-product constant** for water. At 25 °C, K_w equals 1.0×10^{-14} . Thus, we have

$$K_w = [\text{H}_3\text{O}^+][\text{OH}^-] = 1.0 \times 10^{-14} \quad (\text{at } 25 \text{ }^\circ\text{C}) \quad [16.14]$$

Because we use $\text{H}^+(\text{aq})$ and $\text{H}_3\text{O}^+(\text{aq})$ interchangeably to represent the hydrated proton, the autoionization reaction for water can also be written as

Likewise, the expression for K_w can be written in terms of either H_3O^+ or H^+ , and K_w has the same value in either case:

$$K_w = [\text{H}_3\text{O}^+][\text{OH}^-] = [\text{H}^+][\text{OH}^-] = 1.0 \times 10^{-14} \quad (\text{at } 25 \text{ }^\circ\text{C}) \quad [16.16]$$

This equilibrium-constant expression and the value of K_w at 25 °C are extremely important, and you should commit them to memory.

A solution in which $[\text{H}^+] = [\text{OH}^-]$ is said to be *neutral*. In most solutions, however, the H^+ and OH^- concentrations are not equal. As the concentration of one of these ions increases, the concentration of the other must decrease, so that the product of their concentrations always equals 1.0×10^{-14} (▲ FIGURE 16.4).

SAMPLE EXERCISE 16.4 Calculating $[\text{H}^+]$ for Pure Water

Calculate the values of $[\text{H}^+]$ and $[\text{OH}^-]$ in a neutral solution at 25 °C.

SOLUTION

Analyze We are asked to determine the concentrations of H^+ and OH^- ions in a neutral solution at 25 °C.

Plan We will use Equation 16.16 and the fact that, by definition, $[\text{H}^+] = [\text{OH}^-]$ in a neutral solution.

Solve We will represent the concentration of H^+ and OH^- in neutral solution with x . This gives

$$\begin{aligned} [\text{H}^+][\text{OH}^-] &= (x)(x) = 1.0 \times 10^{-14} \\ x^2 &= 1.0 \times 10^{-14} \\ x &= 1.0 \times 10^{-7} \text{ M} = [\text{H}^+] = [\text{OH}^-] \end{aligned}$$

In an acid solution $[\text{H}^+]$ is greater than $1.0 \times 10^{-7} \text{ M}$; in a basic solution $[\text{H}^+]$ is less than $1.0 \times 10^{-7} \text{ M}$.

PRACTICE EXERCISE

Indicate whether solutions with each of the following ion concentrations are neutral, acidic, or basic: (a) $[\text{H}^+] = 4 \times 10^{-9} \text{ M}$; (b) $[\text{OH}^-] = 1 \times 10^{-7} \text{ M}$; (c) $[\text{OH}^-] = 7 \times 10^{-13} \text{ M}$.

Answers: (a) basic, (b) neutral, (c) acidic

What makes Equation 16.16 particularly useful is that it is applicable both to pure water and to any aqueous solution. Although the equilibrium between $\text{H}^+(\text{aq})$ and $\text{OH}^-(\text{aq})$ as well as other ionic equilibria are affected somewhat by the presence of additional ions in solution, it is customary to ignore these ionic effects except in work requiring exceptional accuracy. Thus, Equation 16.16 is taken to be valid for any dilute aqueous solution and can be used to calculate either $[\text{H}^+]$ (if $[\text{OH}^-]$ is known) or $[\text{OH}^-]$ (if $[\text{H}^+]$ is known).

SAMPLE EXERCISE 16.5 Calculating $[\text{H}^+]$ from $[\text{OH}^-]$

Calculate the concentration of $\text{H}^+(\text{aq})$ in (a) a solution in which $[\text{OH}^-]$ is 0.010 M , (b) a solution in which $[\text{OH}^-]$ is $1.8 \times 10^{-9} \text{ M}$. *Note:* In this problem and all that follow, we assume, unless stated otherwise, that the temperature is 25°C .

SOLUTION

Analyze We are asked to calculate the $[\text{H}^+]$ concentration in an aqueous solution where the hydroxide concentration is known.

Plan We can use the equilibrium-constant expression for the auto-ionization of water and the value of K_w to solve for each unknown concentration.

Solve

(a) Using Equation 16.16, we have

$$[\text{H}^+][\text{OH}^-] = 1.0 \times 10^{-14}$$

$$[\text{H}^+] = \frac{(1.0 \times 10^{-14})}{[\text{OH}^-]} = \frac{1.0 \times 10^{-14}}{0.010} = 1.0 \times 10^{-12} \text{ M}$$

This solution is basic because

$$[\text{OH}^-] > [\text{H}^+]$$

(b) In this instance

$$[\text{H}^+] = \frac{(1.0 \times 10^{-14})}{[\text{OH}^-]} = \frac{1.0 \times 10^{-14}}{1.8 \times 10^{-9}} = 5.6 \times 10^{-6} \text{ M}$$

This solution is acidic because

$$[\text{H}^+] > [\text{OH}^-]$$

PRACTICE EXERCISE

Calculate the concentration of $\text{OH}^-(\text{aq})$ in a solution in which (a) $[\text{H}^+] = 2 \times 10^{-6} \text{ M}$;

(b) $[\text{H}^+] = [\text{OH}^-]$; (c) $[\text{H}^+] = 100 \times [\text{OH}^-]$.

Answers: (a) $5 \times 10^{-9} \text{ M}$, (b) $1.0 \times 10^{-7} \text{ M}$, (c) $1.0 \times 10^{-8} \text{ M}$

16.4 THE pH SCALE

The molar concentration of $\text{H}^+(\text{aq})$ in an aqueous solution is usually very small. For convenience, we therefore usually express $[\text{H}^+]$ in terms of **pH**, which is the negative logarithm in base 10 of $[\text{H}^+]$.*

$$\text{pH} = -\log[\text{H}^+] \quad [16.17]$$

If you need to review the use of logarithms, see Appendix A.

We can use Equation 16.17 to calculate the pH of a neutral solution at 25°C (that is, one in which $[\text{H}^+] = 1.0 \times 10^{-7} \text{ M}$):

$$\text{pH} = -\log(1.0 \times 10^{-7}) = -(-7.00) = 7.00$$

The pH of a neutral solution is 7.00 at 25°C . Notice that the pH is reported with two decimal places. We do so because only the numbers to the right of the decimal point are the significant

*Because $[\text{H}^+]$ and $[\text{H}_3\text{O}^+]$ are used interchangeably, you might see pH defined as $-\log[\text{H}_3\text{O}^+]$.

TABLE 16.1 • Relationships among $[H^+]$, $[OH^-]$, and pH at 25 °C

Solution Type	$[H^+]$ (M)	$[OH^-]$ (M)	pH
Acidic	$>1.0 \times 10^{-7}$	$<1.0 \times 10^{-7}$	<7.00
Neutral	1.0×10^{-7}	1.0×10^{-7}	7.00
Basic	$<1.0 \times 10^{-7}$	$>1.0 \times 10^{-7}$	>7.00

figures in a logarithm. Because our original value for the concentration ($1.0 \times 10^{-7} M$) has two significant figures, the corresponding pH has two decimal places (7.00).

What happens to the pH of a solution as we make the solution more and more acidic, so that $[H^+]$ increases? Because of the negative sign in the logarithm term of Equation 16.17, *the pH decreases as $[H^+]$ increases*. For example, the pH of a neutral solution ($[H^+] = 1.0 \times 10^{-7} M$) is 7.00, but when we add sufficient acid to make $[H^+] = 1.0 \times 10^{-3} M$ the pH is

$$\text{pH} = -\log(1.0 \times 10^{-3}) = -(-3.00) = 3.00$$

At 25 °C the pH of an acidic solution is less than 7.00.

We can also calculate the pH of a basic solution, one in which $[OH^-] > 1.0 \times 10^{-7} M$. Suppose $[OH^-] = 2.0 \times 10^{-3} M$. We can use Equation 16.16 to calculate $[H^+]$ for this solution and Equation 16.17 to calculate the pH:

$$[H^+] = \frac{K_w}{[OH^-]} = \frac{1.0 \times 10^{-14}}{2.0 \times 10^{-3}} = 5.0 \times 10^{-12} M$$

$$\text{pH} = -\log(5.0 \times 10^{-12}) = 11.30$$

At 25 °C the pH of a basic solution is greater than 7.00. The relationships among $[H^+]$, $[OH^-]$, and pH are summarized in **▲ TABLE 16.1**.

▲ GIVE IT SOME THOUGHT

Is it possible for a solution to have a negative pH? If so, would that pH signify a basic or acidic solution?

You might think that when $[H^+]$ is very small, as is often the case, it would be unimportant. Nothing is further from the truth. If $[H^+]$ is part of a kinetic rate law, for example, changing its concentration changes the rate. ∞ (Section 14.3) Thus, if the rate law is first order in $[H^+]$, doubling the H^+ concentration doubles the rate even if the change is merely from $1 \times 10^{-7} M$ to $2 \times 10^{-7} M$. In biological systems, many reactions involve proton transfers and have rates that depend on $[H^+]$. Because the speeds of these reactions are crucial, the pH of biological fluids must be maintained within narrow limits. For example, human blood has a normal pH range of 7.35 to 7.45. Illness and even death can result if the pH varies much from this narrow range.

SAMPLE EXERCISE 16.6 Calculating pH from $[H^+]$

Calculate the pH values for the two solutions of Sample Exercise 16.5.

SOLUTION

Analyze We are asked to determine the pH of aqueous solutions for which we have already calculated $[H^+]$.

Plan We can calculate pH using its defining equation, Equation 16.17.

Solve

(a) In the first instance we found $[H^+]$ to be $1.0 \times 10^{-12} M$, so that

$$\text{pH} = -\log(1.0 \times 10^{-12}) = -(-12.00) = 12.00$$

Because 1.0×10^{-12} has two significant figures, the pH has two decimal places, 12.00.

(b) For the second solution, $[H^+] = 5.6 \times 10^{-6} M$. Before performing the calculation, it is helpful to estimate the pH. To do so, we note that $[H^+]$ lies between 1×10^{-6} and 1×10^{-5} . Thus, we expect the pH to lie between 6.0 and 5.0. We use Equation 16.17 to calculate the pH:

$$\text{pH} = -\log(5.6 \times 10^{-6}) = 5.25$$

Check After calculating a pH, it is useful to compare it to your estimate. In this case the pH, as we predicted, falls between 6 and 5. Had the calculated pH and the estimate not agreed, we should have reconsidered our calculation or estimate or both.

PRACTICE EXERCISE

(a) In a sample of lemon juice, $[H^+] = 3.8 \times 10^{-4} M$. What is the pH? (b) A commonly available window-cleaning solution has $[OH^-] = 1.9 \times 10^{-6} M$. What is the pH?

Answers: (a) 3.42, (b) $[H^+] = 5.3 \times 10^{-9} M$, so pH = 8.28

pOH and Other “p” Scales

The negative logarithm is a convenient way of expressing the magnitudes of other small quantities. We use the convention that the negative logarithm of a quantity is labeled “p” (quantity). Thus, we can express the concentration of OH^- as pOH:

$$\text{pOH} = -\log[OH^-] \quad [16.18]$$

Likewise, pK_w equals $-\log K_w$.

By taking the negative logarithm of both sides of the equilibrium-constant expression for water, $K_w = [H^+][OH^-]$, we obtain

$$-\log[H^+] + (-\log[OH^-]) = -\log K_w \quad [16.19]$$

from which we obtain the useful expression

$$\text{pH} + \text{pOH} = 14.00 \quad (\text{at } 25^\circ\text{C}) \quad [16.20]$$

The pH and pOH values characteristic of a number of familiar solutions are shown in ► **FIGURE 16.5**. Notice that a change in $[H^+]$ by a factor of 10 causes the pH to change by 1. Thus, the concentration of $H^+(aq)$ in a solution of pH 6 is 10 times the $H^+(aq)$ concentration in a solution of pH 7.

GIVE IT SOME THOUGHT

If the pOH for a solution is 3.00, what is the pH? Is the solution acidic or basic?

SAMPLE EXERCISE 16.7 Calculating $[H^+]$ from pOH

A sample of freshly pressed apple juice has a pOH of 10.24. Calculate $[H^+]$.

SOLUTION

Analyze We need to calculate $[H^+]$ from pOH.

Plan We will first use Equation 16.20, $\text{pH} + \text{pOH} = 14.00$, to calculate pH from pOH. Then we will use Equation 16.17 to determine the concentration of H^+ .

Solve From Equation 16.20, we have

$$\begin{aligned} \text{pH} &= 14.00 - \text{pOH} \\ \text{pH} &= 14.00 - 10.24 = 3.76 \end{aligned}$$

Next we use Equation 16.17:

$$\text{pH} = -\log[H^+] = 3.76$$

Thus,

$$\log[H^+] = -3.76$$

To find $[H^+]$, we need to determine the *antilogarithm* of -3.76 . Scientific calculators have an antilogarithm function (sometimes labeled INV log or 10^x) that allows us to perform the calculation:

$$[H^+] = \text{antilog}(-3.76) = 10^{-3.76} = 1.7 \times 10^{-4} M$$

Comment The number of significant figures in $[H^+]$ is two because the number of decimal places in the pH is two.

Check Because the pH is between 3.0 and 4.0, we know that $[H^+]$ will be between $1.0 \times 10^{-3} M$ and $1.0 \times 10^{-4} M$. Our calculated $[H^+]$ falls within this estimated range.

PRACTICE EXERCISE

A solution formed by dissolving an antacid tablet has a pH of 9.18. Calculate $[OH^-]$.

Answer: $[OH^-] = 1.5 \times 10^{-5}$

	$[H^+]$ (M)	pH	pOH	$[OH^-]$ (M)	
	1 (1×10^0)	0.0	14.0	1×10^{-14}	
Stomach acid	1×10^{-1}	1.0	13.0	1×10^{-13}	
Lemon juice	1×10^{-2}	2.0	12.0	1×10^{-12}	
Cola, vinegar	1×10^{-3}	3.0	11.0	1×10^{-11}	
Wine	1×10^{-4}	4.0	10.0	1×10^{-10}	
Tomatoes	1×10^{-4}	4.0	10.0	1×10^{-10}

$pH + pOH = 14$
 $[H^+][OH^-] = 1 \times 10^{-14}$

▲ FIGURE 16.5 Concentrations of H^+ and pH values of some common substances at 25 °C.

Measuring pH

The pH of a solution can be measured with a *pH meter* (► FIGURE 16.6). A complete understanding of how this important device works requires a knowledge of electrochemistry, a subject we take up in Chapter 20. In brief, a pH meter consists of a pair of electrodes connected to a meter capable of measuring small voltages, on the order of millivolts. A voltage, which varies with pH, is generated when the electrodes are placed in a solution. This voltage is read by the meter, which is calibrated to give pH.

Although less precise, acid–base indicators can be used to measure pH. An acid–base indicator is a colored substance that can exist in either an acid or a base form. The two forms have different colors. Thus, the indicator has one color at lower pH and another at higher pH. If you know the pH at which the indicator turns from one form to the other, you can determine whether a solution has a higher or lower pH than this value. Litmus, for example, changes color in the vicinity of pH 7. The color change, however, is not very sharp. Red litmus indicates a pH of about 5 or lower, and blue litmus indicates a pH of about 8 or higher.

▲ FIGURE 16.6 A digital pH meter. The device is a millivoltmeter, and the electrodes immersed in a solution produce a voltage that depends on the pH of the solution.

GO FIGURE

Which of these indicators is best suited to distinguish between a solution that is slightly acidic and one that is slightly basic?

Methyl red

Bromthymol blue

Phenolphthalein

▲ FIGURE 16.8 Solutions containing three common acid–base indicators at various pH values.

GO FIGURE

If a colorless solution turns pink when we add phenolphthalein, what can we conclude about the pH of the solution?

	pH range for color change								
	0	2	4	6	8	10	12	14	
Methyl violet	Yellow	[Color gradient]		Violet					
Thymol blue		Red	[Color gradient]		Yellow		Yellow	[Color gradient]	Blue
Methyl orange			Red	[Color gradient]		Yellow			
Methyl red				Red	[Color gradient]		Yellow		
Bromthymol blue					Yellow	[Color gradient]	Blue		
Phenolphthalein						Colorless	[Color gradient]	Pink	
Alizarin yellow R							Yellow	[Color gradient]	Red

▲ FIGURE 16.7 pH ranges for common acid–base indicators. Most indicators have a useful range of about 2 pH units.

Some common indicators are listed in ▲ FIGURE 16.7. The chart tells us, for instance, that methyl red changes color over the pH interval from about 4.5 to 6.0. Below pH 4.5 it is in the acid form, which is red. In the interval between 4.5 and 6.0, it is gradually converted to its basic form, which is yellow. Once the pH rises above 6 the conversion is complete, and the solution is yellow. This color change, along with that of the indicators bromthymol blue and phenolphthalein, is shown in ◀ FIGURE 16.8. Paper tape impregnated with several indicators is widely used for determining approximate pH values.

16.5 STRONG ACIDS AND BASES

The chemistry of an aqueous solution often depends critically on pH. It is therefore important to examine how pH relates to acid and base concentrations. The simplest cases are those involving strong acids and strong bases. Strong acids and bases are *strong electrolytes*, existing in aqueous solution entirely as ions. There are relatively few common strong acids and bases (see Table 4.2).

Strong Acids

The seven most common strong acids include six monoprotic acids (HCl, HBr, HI, HNO₃, HClO₃, and HClO₄), and one diprotic acid (H₂SO₄). Nitric acid (HNO₃) exemplifies the behavior of the monoprotic strong acids. For all practical purposes, an aqueous solution of HNO₃ consists entirely of H₃O⁺ and NO₃[−] ions:

We have not used equilibrium arrows for this equation because the reaction lies entirely to the right. ∞ (Section 4.1) As noted in Section 16.3, we use H₃O⁺(aq) and H⁺(aq) interchangeably to represent the hydrated proton in water. Thus, we can simplify this acid ionization equation to

In an aqueous solution of a strong acid, the acid is normally the only significant source of H^+ ions.* As a result, calculating the pH of a solution of a strong monoprotic acid is straightforward because $[\text{H}^+]$ equals the original concentration of acid. In a 0.20 M solution of $\text{HNO}_3(\text{aq})$, for example, $[\text{H}^+] = [\text{NO}_3^-] = 0.20 \text{ M}$. The situation with the diprotic acid H_2SO_4 is more complex, as we will see in Section 16.6.

SAMPLE EXERCISE 16.8 Calculating the pH of a Strong Acid

What is the pH of a 0.040 M solution of HClO_4 ?

SOLUTION

Analyze and Plan Because HClO_4 is a strong acid, it is completely ionized, giving $[\text{H}^+] = [\text{ClO}_4^-] = 0.040 \text{ M}$.

Solve

$$\text{pH} = -\log(0.040) = 1.40.$$

Check Because $[\text{H}^+]$ lies between 1×10^{-2} and 1×10^{-1} , the pH will be between 2.0 and 1.0. Our calculated pH falls within the estimated range. Furthermore, because the concentration has two significant figures, the pH has two decimal places.

PRACTICE EXERCISE

An aqueous solution of HNO_3 has a pH of 2.34. What is the concentration of the acid?

Answer: 0.0046 M

Strong Bases

The most common soluble strong bases are the ionic hydroxides of the alkali metals, such as NaOH , KOH , and the ionic hydroxides heavier alkaline earth metals, such as $\text{Sr}(\text{OH})_2$. These compounds completely dissociate into ions in aqueous solution. Thus, a solution labeled 0.30 M NaOH consists of 0.30 M $\text{Na}^+(\text{aq})$ and 0.30 M $\text{OH}^-(\text{aq})$; there is essentially no undissociated NaOH .

GIVE IT SOME THOUGHT

Which solution has the higher pH, a 0.001 M solution of NaOH or a 0.001 M solution of $\text{Ba}(\text{OH})_2$?

SAMPLE EXERCISE 16.9 Calculating the pH of a Strong Base

What is the pH of (a) a 0.028 M solution of NaOH , (b) a 0.0011 M solution of $\text{Ca}(\text{OH})_2$?

SOLUTION

Analyze We are asked to calculate the pH of two solutions of strong bases.

Plan We can calculate each pH by either of two equivalent methods. First, we could use Equation 16.16 to calculate $[\text{H}^+]$ and then use Equation 16.17 to calculate the pH. Alternatively, we could use $[\text{OH}^-]$ to calculate pOH and then use Equation 16.20 to calculate the pH.

Solve

(a) NaOH dissociates in water to give one OH^- ion per formula unit. Therefore, the OH^- concentration for the solution in (a) equals the stated concentration of NaOH , namely 0.028 M.

Method 1:

$$[\text{H}^+] = \frac{1.0 \times 10^{-14}}{0.028} = 3.57 \times 10^{-13} \text{ M} \quad \text{pH} = -\log(3.57 \times 10^{-13}) = 12.45$$

Method 2:

$$\text{pOH} = -\log(0.028) = 1.55 \quad \text{pH} = 14.00 - \text{pOH} = 12.45$$

*If the concentration of the acid is 10^{-6} M or less, we also need to consider H^+ ions that result from H_2O autoionization. Normally, the concentration of H^+ from H_2O is so small that it can be neglected.

(b) $\text{Ca}(\text{OH})_2$ is a strong base that dissociates in water to give two OH^- ions per formula unit. Thus, the concentration of $\text{OH}^-(aq)$ for the solution in part (b) is $2 \times (0.0011 M) = 0.0022 M$.

Method 1:

$$[\text{H}^+] = \frac{1.0 \times 10^{-14}}{0.0022} = 4.55 \times 10^{-12} M \quad \text{pH} = -\log(4.55 \times 10^{-12}) = 11.34$$

Method 2:

$$\text{pOH} = -\log(0.0022) = 2.66 \quad \text{pH} = 14.00 - \text{pOH} = 11.34$$

PRACTICE EXERCISE

What is the concentration of a solution of (a) KOH for which the pH is 11.89, (b) $\text{Ca}(\text{OH})_2$ for which the pH is 11.68?

Answers: (a) $7.8 \times 10^{-3} M$, (b) $2.4 \times 10^{-3} M$

Although all of the alkali metal hydroxides are strong electrolytes, LiOH, RbOH, and CsOH are not commonly encountered in the laboratory. The hydroxides of the heavier alkaline earth metals— $\text{Ca}(\text{OH})_2$, $\text{Sr}(\text{OH})_2$, and $\text{Ba}(\text{OH})_2$ —are also strong electrolytes. They have limited solubility, however, so they are used only when high solubility is not critical.

Strongly basic solutions are also created by certain substances that react with water to form $\text{OH}^-(aq)$. The most common of these contain the oxide ion. Ionic metal oxides, especially Na_2O and CaO , are often used in industry when a strong base is needed. The O^{2-} reacts with water to form OH^- , leaving virtually no O^{2-} in the solution:

Thus, a solution formed by dissolving 0.010 mol of $\text{Na}_2\text{O}(s)$ in enough water to form 1.0 L of solution has $[\text{OH}^-] = 0.020 M$ and a pH of 12.30.

GIVE IT SOME THOUGHT

The CH_3^- ion is the conjugate base of CH_4 , and CH_4 shows no evidence of being an acid in water. What happens when CH_3^- is added to water?

16.6 WEAK ACIDS

Most acidic substances are weak acids and therefore only partially ionized in aqueous solution (► FIGURE 16.9). We can use the equilibrium constant for the ionization reaction to express the extent to which a weak acid ionizes. If we represent a general weak acid as HA, we can write the equation for its ionization in either of the following ways, depending on whether the hydrated proton is represented as $\text{H}_3\text{O}^+(aq)$ or $\text{H}^+(aq)$:

or

Because H_2O is the solvent, it is omitted from the equilibrium-constant expression. ∞ (Section 15.4) Thus, we can write the equilibrium-constant expression as either

$$K_c = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]} \quad \text{or} \quad K_c = \frac{[\text{H}^+][\text{A}^-]}{[\text{HA}]}$$

As we did for the ion-product constant for the autoionization of water, we change the subscript on this equilibrium constant to indicate the type of equation to which it corresponds:

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]} \quad \text{or} \quad K_a = \frac{[\text{H}^+][\text{A}^-]}{[\text{HA}]} \quad [16.25]$$

▲ **FIGURE 16.9** Species present in a solution of a strong acid and a weak acid.

The subscript a denotes that K_a is an equilibrium constant for the ionization of an acid, so K_a is called the **acid-dissociation constant**.

▼ **TABLE 16.2** shows the structural formulas, conjugate bases, and K_a values for a number of weak acids. Appendix D provides a more complete list. Many weak acids are organic compounds composed entirely of carbon, hydrogen, and oxygen. These compounds usually contain some hydrogen atoms bonded to carbon atoms and some bonded to oxygen atoms. In almost all cases, the hydrogen atoms bonded to carbon do not ionize in water; instead, the acidic behavior of these compounds is due to the hydrogen atoms attached to oxygen atoms.

TABLE 16.2 • Some Weak Acids in Water at 25 °C

Acid	Structural Formula*	Conjugate Base	K_a
Chlorous (HClO ₂)	$H-O-Cl-O$	ClO_2^-	1.0×10^{-2}
Hydrofluoric (HF)	$H-F$	F^-	6.8×10^{-4}
Nitrous (HNO ₂)	$H-O-N=O$	NO_2^-	4.5×10^{-4}
Benzoic (C ₆ H ₅ COOH)	$H-O-C(=O)-C_6H_5$	$C_6H_5COO^-$	6.3×10^{-5}
Acetic (CH ₃ COOH)	$H-O-C(=O)-CH_3$	CH_3COO^-	1.8×10^{-5}
Hypochlorous (HOCl)	$H-O-Cl$	OCl^-	3.0×10^{-5}
Hydrocyanic (HCN)	$H-C \equiv N$	CN^-	4.9×10^{-10}
Phenol (HOC ₆ H ₅)	$H-O-C_6H_5$	$C_6H_5O^-$	1.3×10^{-10}

*The proton that ionizes is shown in red.

The magnitude of K_a indicates the tendency of the acid to ionize in water: *The larger the value of K_a , the stronger the acid.* Chlorous acid (HClO_2), for example, is the strongest acid in Table 16.2, and phenol (HOC_6H_5) is the weakest. For most weak acids K_a values range from 10^{-2} to 10^{-10} .

GIVE IT SOME THOUGHT

Based on the entries in Table 16.2, which element is most commonly bonded to the acidic hydrogen?

Calculating K_a from pH

In order to calculate either the K_a value for a weak acid or the pH of its solutions, we will use many of the skills for solving equilibrium problems developed in Section 15.5. In many cases the small magnitude of K_a allows us to use approximations to simplify the problem. In doing these calculations, it is important to realize that proton-transfer reactions are generally very rapid. As a result, the measured or calculated pH for a weak acid always represents an equilibrium condition.

SAMPLE EXERCISE 16.10 Calculating K_a from Measured pH

A student prepared a 0.10 M solution of formic acid (HCOOH) and found its pH at 25 °C to be 2.38. Calculate K_a for formic acid at this temperature.

SOLUTION

Analyze We are given the molar concentration of an aqueous solution of weak acid and the pH of the solution, and we are asked to determine the value of K_a for the acid.

Plan Although we are dealing specifically with the ionization of a weak acid, this problem is very similar to the equilibrium problems we encountered in Chapter 15. We can solve this problem using the method first outlined in Sample Exercise 15.9, starting with the chemical reaction and a tabulation of initial and equilibrium concentrations.

Solve The first step in solving any equilibrium problem is to write the equation for the equilibrium reaction. The ionization of formic acid can be written as

The equilibrium-constant expression is

$$K_a = \frac{[\text{H}^+][\text{HCOO}^-]}{[\text{HCOOH}]}$$

From the measured pH, we can calculate $[\text{H}^+]$:

$$\text{pH} = -\log[\text{H}^+] = 2.38$$

$$\log[\text{H}^+] = -2.38$$

$$[\text{H}^+] = 10^{-2.38} = 4.2 \times 10^{-3} M$$

To determine the concentrations of the species involved in the equilibrium, we imagine that the solution is initially 0.10 M in HCOOH molecules. We then consider the ionization of the acid into H^+ and HCOO^- . For each HCOOH molecule that ionizes, one H^+ ion and one HCOO^- ion are produced in solution. Because the pH measurement indicates that $[\text{H}^+] = 4.2 \times 10^{-3} M$ at equilibrium, we can construct the following table:

	$\text{HCOOH}(aq)$	\rightleftharpoons	$\text{H}^+(aq)$	+	$\text{HCOO}^-(aq)$
Initial	0.10 M		0		0
Change	$-4.2 \times 10^{-3} M$		$+4.2 \times 10^{-3} M$		$+4.2 \times 10^{-3} M$
Equilibrium	$(0.10 - 4.2 \times 10^{-3}) M$		$4.2 \times 10^{-3} M$		$4.2 \times 10^{-3} M$

Notice that we have neglected the very small concentration of $\text{H}^+(aq)$ due to H_2O autoionization. Notice also that the amount of HCOOH that ionizes is very small compared with the initial concentration of the acid. To the number of significant figures we are using, the subtraction yields 0.10 M:

$$(0.10 - 4.2 \times 10^{-3}) M \approx 0.10 M$$

We can now insert the equilibrium concentrations into the expression for K_a :

$$K_a = \frac{(4.2 \times 10^{-3})(4.2 \times 10^{-3})}{0.10} = 1.8 \times 10^{-4}$$

Check The magnitude of our answer is reasonable because K_a for a weak acid is usually between 10^{-2} and 10^{-10} .

PRACTICE EXERCISE

Niacin, one of the B vitamins, has the molecular structure

A 0.020 M solution of niacin has a pH of 3.26. What is the acid-dissociation constant for niacin?

Answer: 1.5×10^{-5}

Percent Ionization

We have seen that the magnitude of K_a indicates the strength of a weak acid. Another measure of acid strength is **percent ionization**, defined as

$$\text{Percent ionization} = \frac{\text{concentration ionized}}{\text{original concentration}} \times 100\% \quad [16.26]$$

The stronger the acid, the greater the percent ionization.

For any acid, the concentration of acid that ionizes equals the concentration of $\text{H}^+(aq)$ that forms, assuming that H_2O autoionization is negligible. Thus, the percent ionization for an acid HA is also given by

$$\text{Percent ionization} = \frac{[\text{H}^+]_{\text{equilibrium}}}{[\text{HA}]_{\text{initial}}} \times 100\% \quad [16.27]$$

For example, a 0.035 M solution of HNO_2 contains $3.7 \times 10^{-3} M \text{H}^+(aq)$ and its percent ionization is

$$\text{Percent ionization} = \frac{[\text{H}^+]_{\text{equilibrium}}}{[\text{HNO}_2]_{\text{initial}}} \times 100\% = \frac{3.7 \times 10^{-3} M}{0.035 M} \times 100\% = 11\%$$

SAMPLE EXERCISE 16.11 Calculating Percent Ionization

As calculated in Sample Exercise 16.10, a 0.10 M solution of formic acid (HCOOH) contains $4.2 \times 10^{-3} M \text{H}^+(aq)$. Calculate the percentage of the acid that is ionized.

SOLUTION

Analyze We are given the molar concentration of an aqueous solution of weak acid and the equilibrium concentration of $\text{H}^+(aq)$ and asked to determine the percent ionization of the acid.

Plan The percent ionization is given by Equation 16.27.

Solve

$$\text{Percent ionization} = \frac{[\text{H}^+]_{\text{equilibrium}}}{[\text{HCOOH}]_{\text{initial}}} \times 100\% = \frac{4.2 \times 10^{-3} M}{0.10 M} \times 100\% = 4.2\%$$

PRACTICE EXERCISE

A 0.020 M solution of niacin has a pH of 3.26. Calculate the percent ionization of the niacin.

Answer: 2.7%

Using K_a to Calculate pH

Knowing the value of K_a and the initial concentration of a weak acid, we can calculate the concentration of $\text{H}^+(aq)$ in a solution of the acid. Let's calculate the pH at 25 °C of a 0.30 M solution of acetic acid (CH_3COOH), the weak acid responsible for the characteristic odor and acidity of vinegar.

1. Our first step is to write the ionization equilibrium:

Notice that the hydrogen that ionizes is the one attached to an oxygen atom.

2. The second step is to write the equilibrium-constant expression and the value for the equilibrium constant. Taking $K_a = 1.8 \times 10^{-5}$ from Table 16.2, we write

$$K_a = \frac{[\text{H}^+][\text{CH}_3\text{COO}^-]}{[\text{CH}_3\text{COOH}]} = 1.8 \times 10^{-5} \quad [16.29]$$

3. The third step is to express the concentrations involved in the equilibrium reaction. This can be done with a little accounting, as described in Sample Exercise 16.10. Because we want to find the equilibrium value for $[\text{H}^+]$, let's call this quantity x . The concentration of acetic acid before any of it ionizes is 0.30 M. The chemical equation tells us that for each molecule of CH_3COOH that ionizes, one $\text{H}^+(aq)$ and one $\text{CH}_3\text{COO}^-(aq)$ are formed. Consequently, if x moles per liter of $\text{H}^+(aq)$ form at equilibrium, x moles per liter of $\text{CH}_3\text{COO}^-(aq)$ must also form and x moles per liter of CH_3COOH must be ionized:

Initial	0.30 M	0	0
Change	$-x$ M	$+x$ M	$+x$ M
Equilibrium	$(0.30 - x)$ M	x M	x M

4. The fourth step is to substitute the equilibrium concentrations into the equilibrium-constant expression and solve for x :

$$K_a = \frac{[\text{H}^+][\text{CH}_3\text{COO}^-]}{[\text{CH}_3\text{COOH}]} = \frac{(x)(x)}{0.30 - x} = 1.8 \times 10^{-5} \quad [16.30]$$

This expression leads to a quadratic equation in x , which we can solve by using either an equation-solving calculator or the quadratic formula. We can simplify the problem, however, by noting that the value of K_a is quite small. As a result, we anticipate that the equilibrium lies far to the left and that x is much smaller than the initial concentration of acetic acid. Thus, we *assume* that x is negligible relative to 0.30, so that $0.30 - x$ is essentially equal to 0.30. We can (and should!) check the validity of this assumption when we finish the problem. By using this assumption, Equation 16.30 becomes

$$K_a = \frac{x^2}{0.30} = 1.8 \times 10^{-5}$$

Solving for x , we have

$$\begin{aligned} x^2 &= (0.30)(1.8 \times 10^{-5}) = 5.4 \times 10^{-6} \\ x &= \sqrt{5.4 \times 10^{-6}} = 2.3 \times 10^{-3} \\ [\text{H}^+] &= x = 2.3 \times 10^{-3} \text{ M} \\ \text{pH} &= -\log(2.3 \times 10^{-3}) = 2.64 \end{aligned}$$

Now we check the validity of our simplifying assumption that $0.30 - x \approx 0.30$. The value of x we determined is so small that, for this number of significant figures, the assumption is entirely valid. We are thus satisfied that the assumption was a reasonable

one to make. Because x represents the moles per liter of acetic acid that ionize, we see that, in this particular case, less than 1% of the acetic acid molecules ionize:

$$\text{Percent ionization of CH}_3\text{COOH} = \frac{0.0023 \text{ M}}{0.30 \text{ M}} \times 100\% = 0.77\%$$

As a general rule, if x is more than about 5% of the initial concentration value, it is better to use the quadratic formula. You should always check the validity of any simplifying assumptions after you have finished solving a problem.

GIVE IT SOME THOUGHT

Why can we generally assume that the equilibrium concentration of a weak acid equals its initial concentration?

Finally, we can compare the pH value of this weak acid with the pH of a solution of a strong acid of the same concentration. The pH of the 0.30 M acetic acid is 2.64, but the pH of a 0.30 M solution of a strong acid such as HCl is $-\log(0.30) = 0.52$. As expected, the pH of a solution of a weak acid is higher than that of a solution of a strong acid of the same molarity. (Remember, the higher the pH value, the *less* acidic the solution.)

SAMPLE EXERCISE 16.12 Using K_a to Calculate pH

Calculate the pH of a 0.20 M solution of HCN. (Refer to Table 16.2 or Appendix D for the value of K_a .)

SOLUTION

Analyze We are given the molarity of a weak acid and are asked for the pH. From Table 16.2, K_a for HCN is 4.9×10^{-10} .

Plan We proceed as in the example just worked in the text, writing the chemical equation and constructing a table of initial and equilibrium concentrations in which the equilibrium concentration of H^+ is our unknown.

Solve Writing both the chemical equation for the ionization reaction that forms $\text{H}^+(\text{aq})$ and the equilibrium-constant (K_a) expression for the reaction:

$$K_a = \frac{[\text{H}^+][\text{CN}^-]}{[\text{HCN}]} = 4.9 \times 10^{-10}$$

Next, we tabulate the concentrations of the species involved in the equilibrium reaction, letting $x = [\text{H}^+]$ at equilibrium:

Initial	0.20 M	0	0
Change	$-x \text{ M}$	$+x \text{ M}$	$+x \text{ M}$
Equilibrium	$(0.20 - x) \text{ M}$	$x \text{ M}$	$x \text{ M}$

Substituting the equilibrium concentrations into the equilibrium-constant expression yields

$$K_a = \frac{(x)(x)}{0.20 - x} = 4.9 \times 10^{-10}$$

We next make the simplifying approximation that x , the amount of acid that dissociates, is small compared with the initial concentration of acid, $0.20 - x \approx 0.20$. Thus,

$$\frac{x^2}{0.20} = 4.9 \times 10^{-10}$$

Solving for x , we have

$$x^2 = (0.20)(4.9 \times 10^{-10}) = 0.98 \times 10^{-10}$$

$$x = \sqrt{0.98 \times 10^{-10}} = 9.9 \times 10^{-6} \text{ M} = [\text{H}^+]$$

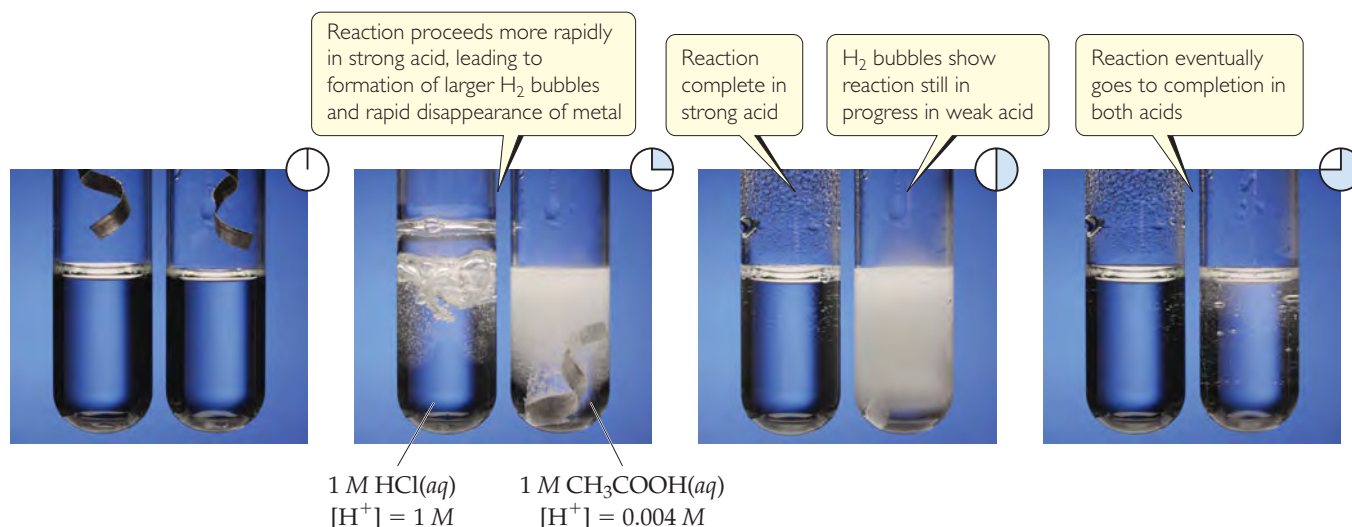

A concentration of $9.9 \times 10^{-6} \text{ M}$ is much smaller than 5% of 0.20, the initial HCN concentration. Our simplifying approximation is therefore appropriate. We now calculate the pH of the solution:

$$\text{pH} = -\log[\text{H}^+] = -\log(9.9 \times 10^{-6}) = 5.00$$

PRACTICE EXERCISE

The K_a for niacin (Practice Exercise 16.10) is 1.5×10^{-5} . What is the pH of a 0.010 M solution of niacin?

Answer: 3.41

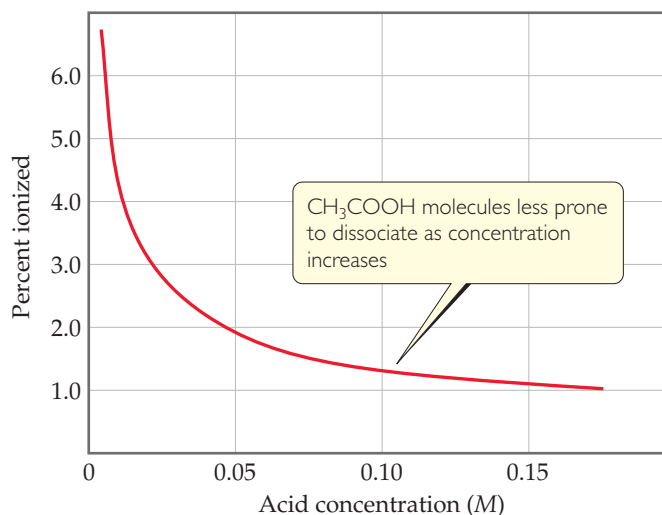

▲ **FIGURE 16.10** Rates of the same reaction run in a weak acid and a strong acid. The bubbles are H_2 gas, which along with metal cations, is produced when a metal is oxidized by an acid (Section 4.4).

The properties of an acid solution that relate directly to the concentration of $\text{H}^+(aq)$, such as electrical conductivity and rate of reaction with an active metal, are less evident for a solution of a weak acid than for a solution of a strong acid of the same concentration. ▲ **FIGURE 16.10** presents an experiment that demonstrates this difference with $1\text{ M CH}_3\text{COOH}$ and 1 M HCl . The $1\text{ M CH}_3\text{COOH}$ contains only $0.004\text{ M H}^+(aq)$, whereas the 1 M HCl solution contains $1\text{ M H}^+(aq)$. As a result, the reaction rate with the metal is much faster in the HCl solution.

As the concentration of a weak acid increases, the equilibrium concentration of $\text{H}^+(aq)$ increases, as expected. However, as shown in ▼ **FIGURE 16.11**, the percent ionization decreases as the concentration increases. Thus, the concentration of $\text{H}^+(aq)$ is not directly proportional to the concentration of the weak acid. For example, doubling the concentration of a weak acid does not double the concentration of $\text{H}^+(aq)$.

GO FIGURE

Is the trend observed in this graph consistent with Le Châtelier's principle? Explain.

▲ **FIGURE 16.11** Effect of concentration on percent ionization in an acetic acid solution.

SAMPLE EXERCISE 16.13 Using K_a to Calculate Percent Ionization

Calculate the percentage of HF molecules ionized in (a) a 0.10 M HF solution, (b) a 0.010 M HF solution.

SOLUTION

Analyze We are asked to calculate the percent ionization of two HF solutions of different concentration. From Appendix D, we find $K_a = 6.8 \times 10^{-4}$.

Plan We approach this problem as we have previous equilibrium problems. We begin by writing the chemical equation for the equilibrium and tabulating the known and unknown concentrations of all species. We then substitute the equilibrium concentrations into the equilibrium-constant expression and solve for the unknown concentration, that of H^+ .

Solve

(a) The equilibrium reaction and equilibrium concentrations are as follows:

	HF(aq)	\rightleftharpoons	$H^+(aq)$	+	$F^-(aq)$
Initial	0.10 M		0		0
Change	$-x$ M		$+x$ M		$+x$ M
Equilibrium	$(0.10 - x)$ M		x M		x M

The equilibrium-constant expression is

$$K_a = \frac{[H^+][F^-]}{[HF]} = \frac{(x)(x)}{0.10 - x} = 6.8 \times 10^{-4}$$

When we try solving this equation using the approximation $0.10 - x \approx 0.10$ (that is, by neglecting the concentration of acid that ionizes), we obtain

$$x = 8.2 \times 10^{-3} \text{ M}$$

Because this value is greater than 5% of 0.10 M, however, we should work the problem without the approximation. Rearranging our equation and writing it in standard quadratic form, we have

$$\begin{aligned} x^2 &= (0.10 - x)(6.8 \times 10^{-4}) \\ &= 6.8 \times 10^{-5} - (6.8 \times 10^{-4})x \\ x^2 + (6.8 \times 10^{-4})x - 6.8 \times 10^{-5} &= 0 \end{aligned}$$

Substituting these values in the standard quadratic formula gives

$$\begin{aligned} x &= \frac{-6.8 \times 10^{-4} \pm \sqrt{(6.8 \times 10^{-4})^2 - 4(-6.8 \times 10^{-5})}}{2} \\ &= \frac{-6.8 \times 10^{-4} \pm 1.6 \times 10^{-2}}{2} \end{aligned}$$

Of the two solutions, only the one that gives a positive value for x is chemically reasonable. Thus,

$$x = [H^+] = [F^-] = 7.9 \times 10^{-3} \text{ M}$$

From our result, we can calculate the percent of molecules ionized:

$$\begin{aligned} \text{Percent ionization of HF} &= \frac{\text{concentration ionized}}{\text{original concentration}} \times 100\% \\ &= \frac{7.9 \times 10^{-3} \text{ M}}{0.10 \text{ M}} \times 100\% = 7.9\% \end{aligned}$$

(b) Proceeding similarly for the 0.010 M solution, we have

$$\frac{x^2}{0.010 - x} = 6.8 \times 10^{-4}$$

Solving the resultant quadratic expression, we obtain

$$x = [H^+] = [F^-] = 2.3 \times 10^{-3} \text{ M}$$

The percentage of molecules ionized is

$$\frac{0.0023 \text{ M}}{0.010 \text{ M}} \times 100\% = 23\%$$

Comment Notice that if we do not use the quadratic formula, we calculate 8.2% ionization for (a) and 26% ionization for (b). Notice also that in diluting the solution by a factor of 10, the percentage of molecules ionized increases by a factor of 3. This result is in accord with what we see in Figure 16.11. It is also what we expect from Le

Châtelier's principle. ∞ (Section 15.7) There are more "particles" or reaction components on the right side of the equation than on the left. Dilution causes the reaction to shift in the direction of the larger number of particles (toward the product side) because this counters the effect of the decreasing concentration of particles.

PRACTICE EXERCISE

In Practice Exercise 16.11, we found that the percent ionization of niacin ($K_a = 1.5 \times 10^{-5}$) in a 0.020 M solution is 2.7%. Calculate the percentage of niacin molecules ionized in a solution that is (a) 0.010 M, (b) 1.0×10^{-3} M.

Answers: (a) 3.9%, (b) 12%

GO FIGURE
Citric acid has four hydrogens bonded to oxygen. How does the hydrogen that is not an acidic proton differ from the other three?

▲ **FIGURE 16.12** The structure of the polyprotic acid, citric acid.

Polyprotic Acids

Many acids have more than one ionizable H atom. These acids are known as **polyprotic acids**. For example, with sulfurous acid (H_2SO_3) we have the successive ionizations

Note that the acid-dissociation constants are labeled K_{a1} and K_{a2} . The numbers on the constants refer to the particular proton of the acid that is ionizing. Thus, K_{a2} always refers to the equilibrium involving removal of the second proton of a polyprotic acid.

Note that K_{a2} for sulfurous acid is much smaller than K_{a1} . Because of electrostatic attractions, we would expect a positively charged proton to be lost more readily from the neutral H_2SO_3 molecule than from the negatively charged HSO_3^- ion. This observation is general: *It is always easier to remove the first proton from a polyprotic acid than to remove the second.* Similarly, for an acid with three ionizable protons, it is easier to remove the second proton than the third. Thus, the K_a values become successively smaller as successive protons are removed.

▲ GIVE IT SOME THOUGHT

What is meant by the symbol K_{a3} for H_3PO_4 ?

The acid-dissociation constants for common polyprotic acids are listed in ▼ **TABLE 16.3**, and Appendix D provides a more complete list. The structure of citric acid illustrates the presence of multiple ionizable protons ◀ **FIGURE 16.12**.

Notice in Table 16.3 that in most cases the K_a values for successive losses of protons differ by a factor of at least 10^3 . Notice also that the value of K_{a1} for sulfuric acid is listed simply as “large.” Sulfuric acid is a strong acid with respect to the removal of the first proton. Thus, the reaction for the first ionization step lies completely to the right:

However, HSO_4^- is a weak acid for which $K_{a2} = 1.2 \times 10^{-2}$.

For many polyprotic acids K_{a1} is much larger than subsequent dissociation constants, in which case the $\text{H}^+(aq)$ in the solution comes almost entirely from the first ionization reaction. As long as successive K_a values differ by a factor of 10^3 or more, it is possible to obtain a satisfactory estimate of the pH of polyprotic acid solutions by treating the acids as if they were monoprotic, considering only K_{a1} .

TABLE 16.3 • Acid-Dissociation Constants of Some Common Polyprotic Acids

Name	Formula	K_{a1}	K_{a2}	K_{a3}
Ascorbic	$\text{H}_2\text{C}_6\text{H}_6\text{O}_6$	8.0×10^{-5}	1.6×10^{-12}	
Carbonic	H_2CO_3	4.3×10^{-7}	5.6×10^{-11}	
Citric	$\text{H}_3\text{C}_6\text{H}_5\text{O}_7$	7.4×10^{-4}	1.7×10^{-5}	4.0×10^{-7}
Oxalic	$\text{H}_2\text{C}_2\text{O}_4$	5.9×10^{-2}	6.4×10^{-5}	
Phosphoric	H_3PO_4	7.5×10^{-3}	6.2×10^{-8}	4.2×10^{-13}
Sulfurous	H_2SO_3	1.7×10^{-2}	6.4×10^{-8}	
Sulfuric	H_2SO_4	Large	1.2×10^{-2}	
Tartaric	$\text{H}_2\text{C}_4\text{H}_4\text{O}_6$	1.0×10^{-3}	4.6×10^{-5}	

SAMPLE EXERCISE 16.14 Calculating the pH of a Polyprotic Acid Solution

The solubility of CO_2 in water at 25°C and 0.1 atm is 0.0037 M . The common practice is to assume that all the dissolved CO_2 is in the form of carbonic acid (H_2CO_3), which is produced in the reaction

What is the pH of a 0.0037 M solution of H_2CO_3 ?

SOLUTION

Analyze We are asked to determine the pH of a 0.0037 M solution of a polyprotic acid.

Plan H_2CO_3 is a diprotic acid; the two acid-dissociation constants, K_{a1} and K_{a2} (Table 16.3), differ by more than a factor of 10^3 . Consequently, the pH can be determined by considering only K_{a1} , thereby treating the acid as if it were a monoprotic acid.

Solve Proceeding as in Sample Exercises 16.12 and 16.13, we can write the equilibrium reaction and equilibrium concentrations as

Initial	0.0037 M	0	0
Change	$-x\text{ M}$	$+x\text{ M}$	$+x\text{ M}$
Equilibrium	$(0.0037 - x)\text{ M}$	$x\text{ M}$	$x\text{ M}$

The equilibrium-constant expression is

$$K_{a1} = \frac{[\text{H}^+][\text{HCO}_3^-]}{[\text{H}_2\text{CO}_3]} = \frac{(x)(x)}{0.0037 - x} = 4.3 \times 10^{-7}$$

Solving this equation using an equation-solving calculator, we get

$$x = 4.0 \times 10^{-5}\text{ M}$$

Alternatively, because K_{a1} is small, we can make the simplifying approximation that x is small, so that

$$0.0037 - x \approx 0.0037$$

Thus,

$$\frac{(x)(x)}{0.0037} = 4.3 \times 10^{-7}$$

Solving for x , we have

$$x^2 = (0.0037)(4.3 \times 10^{-7}) = 1.6 \times 10^{-9}$$

$$x = [\text{H}^+] = [\text{HCO}_3^-] = \sqrt{1.6 \times 10^{-9}} = 4.0 \times 10^{-5}\text{ M}$$

Because we get the same value (to 2 significant figures) our simplifying assumption was justified. The pH is therefore

$$\text{pH} = -\log[\text{H}^+] = -\log(4.0 \times 10^{-5}) = 4.40$$

Comment If we were asked for $[\text{CO}_3^{2-}]$, we would need to use K_{a2} . Let's illustrate that calculation. Using our calculated values of $[\text{HCO}_3^-]$ and $[\text{H}^+]$ and setting $[\text{CO}_3^{2-}] = y$, we have

Initial	$4.0 \times 10^{-5}\text{ M}$	$4.0 \times 10^{-5}\text{ M}$	0
Change	$-y\text{ M}$	$+y\text{ M}$	$+y\text{ M}$
Equilibrium	$(4.0 \times 10^{-5} - y)\text{ M}$	$(4.0 \times 10^{-5} + y)\text{ M}$	$y\text{ M}$

Assuming that y is small relative to 4.0×10^{-5} , we have

$$K_{a2} = \frac{[\text{H}^+][\text{CO}_3^{2-}]}{[\text{HCO}_3^-]} = \frac{(4.0 \times 10^{-5})(y)}{4.0 \times 10^{-5}} = 5.6 \times 10^{-11}$$

$$y = 5.6 \times 10^{-11}\text{ M} = [\text{CO}_3^{2-}]$$

This value is indeed very small compared with 4.0×10^{-5} , showing that our assumption was justified. It also shows that the ionization of HCO_3^- is negligible relative to that of H_2CO_3 , as far as production of H^+ is concerned. However, it is the *only* source of CO_3^{2-} , which has a very low concentration in the solution. Our calculations thus tell us

that in a solution of carbon dioxide in water, most of the CO_2 is in the form of CO_2 or H_2CO_3 , only a small fraction ionizes to form H^+ and HCO_3^- , and an even smaller fraction ionizes to give CO_3^{2-} . Notice also that $[\text{CO}_3^{2-}]$ is numerically equal to K_{a2} .

PRACTICE EXERCISE

(a) Calculate the pH of a 0.020 M solution of oxalic acid ($\text{H}_2\text{C}_2\text{O}_4$). (See Table 16.3 for K_{a1} and K_{a2} .) (b) Calculate the concentration of oxalate ion, $[\text{C}_2\text{O}_4^{2-}]$, in this solution.

Answers: (a) $\text{pH} = 1.80$, (b) $[\text{C}_2\text{O}_4^{2-}] = 6.4 \times 10^{-5}\text{ M}$

16.7 WEAK BASES

Many substances behave as weak bases in water. Weak bases react with water, abstracting protons from H_2O , thereby forming the conjugate acid of the base and OH^- ions:

The equilibrium-constant expression for this reaction can be written as

$$K_b = \frac{[\text{BH}^+][\text{OH}^-]}{[\text{B}]} \quad [16.34]$$

Water is the solvent, so it is omitted from the equilibrium-constant expression. The most commonly encountered weak base is ammonia:

As with K_w and K_a , the subscript b in K_b denotes that the equilibrium constant refers to a particular type of reaction, namely the ionization of a weak base in water. The constant K_b , the **base-dissociation constant**, always refers to the equilibrium in which a base reacts with H_2O to form the corresponding conjugate acid and OH^- .

▼ **TABLE 16.4** lists the Lewis structures, conjugate acids, and K_b values for a number of weak bases in water. Appendix D includes a more extensive list. These bases contain one or more lone pairs of electrons because a lone pair is necessary to form the bond with H^+ . Notice that in the neutral molecules in Table 16.4, the lone pairs are on nitrogen atoms. The other bases listed are anions derived from weak acids.

TABLE 16.4 • Some Weak Bases in Water at 25 °C

Base	Structural Formula*	Conjugate Acid	K_b
Ammonia (NH_3)		NH_4^+	1.8×10^{-5}
Pyridine ($\text{C}_5\text{H}_5\text{N}$)		$\text{C}_5\text{H}_5\text{NH}^+$	1.7×10^{-9}
Hydroxylamine (HONH_2)		HONH_3^+	1.1×10^{-8}
Methylamine (CH_3NH_2)		CH_3NH_3^+	4.4×10^{-4}
Hydrosulfide ion (HS^-)		H_2S	1.8×10^{-7}
Carbonate ion (CO_3^{2-})		HCO_3^-	1.8×10^{-4}
Hypochlorite ion (ClO^-)		HClO	3.3×10^{-7}

*The atom that accepts the proton is shown in blue.

SAMPLE EXERCISE 16.15 Using K_b to Calculate OH^-

Calculate the concentration of OH^- in a 0.15 M solution of NH_3 .

SOLUTION

Analyze We are given the concentration of a weak base and asked to determine the concentration of OH^- .

Plan We will use essentially the same procedure here as used in solving problems involving the ionization of weak acids, that is, write the chemical equation and tabulate initial and equilibrium concentrations.

Solve The ionization reaction and equilibrium-constant expression are

The equilibrium concentrations are (We ignore the concentration of H_2O because it is not involved in the equilibrium-constant expression.)

	$\text{NH}_3(aq)$	+	$\text{H}_2\text{O}(l)$	\rightleftharpoons	$\text{NH}_4^+(aq)$	+	OH^-
Initial	0.15 M		—		0		0
Change	$-x$ M		—		$+x$ M		$+x$ M
Equilibrium	$(0.15 - x)$ M		—		x M		x M

Inserting these quantities into the equilibrium-constant expression gives

$$K_b = \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]} = \frac{(x)(x)}{0.15 - x} = 1.8 \times 10^{-5}$$

Because K_b is small, the amount of NH_3 that reacts with water is much smaller than the NH_3 concentration, and so we can neglect x relative to 0.15 M. Then we have

$$\frac{x^2}{0.15} = 1.8 \times 10^{-5}$$

$$x^2 = (0.15)(1.8 \times 10^{-5}) = 2.7 \times 10^{-6}$$

$$x = [\text{NH}_4^+] = [\text{OH}^-] = \sqrt{2.7 \times 10^{-6}} = 1.6 \times 10^{-3} \text{ M}$$

Check The value obtained for x is only about 1% of the NH_3 concentration, 0.15 M. Therefore, neglecting x relative to 0.15 was justified.

Comment You may be asked to find the pH of a solution of a weak base. Once you have found $[\text{OH}^-]$, you can proceed as in Sample Exercise 16.9, where we calculated the pH of a strong base. In the present sample exercise, we have seen that the 0.15 M solution of NH_3 contains

$[\text{OH}^-] = 1.6 \times 10^{-3} \text{ M}$. Thus, $\text{pOH} = -\log(1.6 \times 10^{-3}) = 2.80$, and $\text{pH} = 14.00 - 2.80 = 11.20$. The pH of the solution is above 7 because we are dealing with a solution of a base.

PRACTICE EXERCISE

Which of the following compounds should produce the highest pH as a 0.05 M solution: pyridine, methylamine, or nitrous acid?

Answer: methylamine (because it has the larger K_b value of the two amine bases in the list)

Types of Weak Bases

Weak bases fall into two general categories. The first category is neutral substances that have an atom with a nonbonding pair of electrons that can accept a proton. Most of these bases, including all uncharged bases in Table 16.4, contain a nitrogen atom. These substances include ammonia and a related class of compounds called **amines** (► **FIGURE 16.13**). In organic amines, at least one N—H bond in NH_3 is replaced with an N—C bond. Like NH_3 , amines can abstract a proton from a water molecule by forming an N—H bond, as shown here for methylamine:

GO FIGURE

When hydroxylamine acts as a base, which atom accepts the proton?

▲ **FIGURE 16.13** Structures of ammonia and two simple amines.

Anions of weak acids make up the second general category of weak bases. In an aqueous solution of sodium hypochlorite (NaClO), for example, NaClO dissociates to Na⁺ and ClO[−] ions. The Na⁺ ion is always a spectator ion in acid–base reactions. ∞ (Section 4.3) The ClO[−] ion, however, is the conjugate base of a weak acid, hypochlorous acid. Consequently, the ClO[−] ion acts as a weak base in water:

In Figure 16.5 we saw that bleach is quite basic (pH values of 12–13). Common chlorine bleach is typically a 5% NaOCl solution.

SAMPLE EXERCISE 16.16 Using pH to Determine the Concentration of a Salt

A solution made by adding solid sodium hypochlorite (NaClO) to enough water to make 2.00 L of solution has a pH of 10.50. Using the information in Equation 16.37, calculate the number of moles of NaClO added to the water.

SOLUTION

Analyze NaClO is an ionic compound consisting of Na⁺ and ClO[−] ions. As such, it is a strong electrolyte that completely dissociates in solution into Na⁺, a spectator ion, and ClO[−] ion, a weak base with $K_b = 3.3 \times 10^{-7}$ (Equation 16.37). Given this information we must calculate the number of moles of NaClO needed to raise the basicity of 2.00-L of water to 10.50.

Plan From the pH, we can determine the equilibrium concentration of OH[−]. We can then construct a table of initial and equilibrium concentrations in which the initial concentration of ClO[−] is our unknown. We can calculate [ClO[−]] using the expression for K_b .

Solve We can calculate [OH[−]] by using either Equation 16.16 or Equation 16.20; we will use the latter method here:

$$\begin{aligned} \text{pOH} &= 14.00 - \text{pH} = 14.00 - 10.50 = 3.50 \\ [\text{OH}^-] &= 10^{-3.50} = 3.2 \times 10^{-4} \text{ M} \end{aligned}$$

This concentration is high enough that we can assume that Equation 16.37 is the only source of OH[−]; that is, we can neglect any OH[−] produced by the autoionization of H₂O. We now assume a value of x for the initial concentration of ClO[−] and solve the equilibrium problem in the usual way.

We now use the expression for the base-dissociation constant to solve for x :

	ClO [−] (aq)	+	H ₂ O(l)	⇌	HClO(aq)	+	OH [−] (aq)
Initial	$x \text{ M}$		—		0		0
Change	$-3.2 \times 10^{-4} \text{ M}$		—		$+3.2 \times 10^{-4} \text{ M}$		$+3.2 \times 10^{-4} \text{ M}$
Equilibrium	$(x - 3.2 \times 10^{-4}) \text{ M}$		—		$3.2 \times 10^{-4} \text{ M}$		$3.2 \times 10^{-4} \text{ M}$

$$K_b = \frac{[\text{HClO}][\text{OH}^-]}{[\text{ClO}^-]} = \frac{(3.2 \times 10^{-4})^2}{x - 3.2 \times 10^{-4}} = 3.3 \times 10^{-7}$$

$$x = \frac{(3.2 \times 10^{-4})^2}{3.3 \times 10^{-7}} + (3.2 \times 10^{-4}) = 0.31 \text{ M}$$

We say that the solution is 0.31 M in NaClO even though some of the ClO^- ions have reacted with water. Because the solution is 0.31 M in NaClO and the total volume of solution is 2.00 L, 0.62 mol of NaClO is the amount of the salt that was added to the water.

PRACTICE EXERCISE

What is the molarity of an aqueous NH_3 solution that has a pH of 11.17?

Answer: 0.12 M

16.8 | RELATIONSHIP BETWEEN K_a AND K_b

We have seen in a qualitative way that the stronger acids have the weaker conjugate bases. To see if we can find a corresponding *quantitative* relationship, let's consider the NH_4^+ and NH_3 conjugate acid–base pair. Each species reacts with water. For the acid, NH_4^+ the reaction is:

or written in its simpler form:

and for the base NH_3 :

and each equilibrium is expressed by a dissociation constant:

$$K_a = \frac{[\text{NH}_3][\text{H}^+]}{[\text{NH}_4^+]} \quad K_b = \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]}$$

When we add Equations 16.38 and 16.39, the NH_4^+ and NH_3 species cancel and we are left with the autoionization of water:

Recall that when two equations are added to give a third, the equilibrium constant associated with the third equation equals the product of the equilibrium constants of the first two equations. ∞ (Section 15.3)

Applying this rule to our present example, when we multiply K_a and K_b , we obtain

$$\begin{aligned} K_a \times K_b &= \left(\frac{[\text{NH}_3][\text{H}^+]}{[\text{NH}_4^+]} \right) \left(\frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]} \right) \\ &= [\text{H}^+][\text{OH}^-] = K_w \end{aligned}$$

Thus, the product of K_a and K_b is the ion-product constant for water, K_w (Equation 16.16). We expect this result because adding Equations 16.38 and 16.39 gave us the autoionization equilibrium for water, for which the equilibrium constant is K_w .

This relationship is so important that it should receive special attention: *The product of the acid-dissociation constant for an acid and the base-dissociation constant for its conjugate base equals the ion-product constant for water:*

$$K_a \times K_b = K_w \quad [16.40]$$

As the strength of an acid increases (K_a gets larger), the strength of its conjugate base must decrease (K_b gets smaller) so that the product $K_a \times K_b$ remains 1.0×10^{-14} at 25 °C. ► **TABLE 16.5** demonstrates this relationship. Remember, this important relationship applies *only* to conjugate acid–base pairs.

By using Equation 16.40, we can calculate K_b for any weak base if we know K_a for its conjugate acid. Similarly, we can calculate K_a for a weak acid if we know K_b for its conjugate base. As a practical consequence, ionization constants are often listed for only one member of a conjugate acid–base pair. For example, Appendix D does not contain K_b

TABLE 16.5 • Some Conjugate Acid–Base Pairs

Acid	K_a	Base	K_b
HNO_3	(Strong acid)	NO_3^-	(Negligible basicity)
HF	6.8×10^{-4}	F^-	1.5×10^{-11}
$\text{HC}_2\text{H}_3\text{O}_2$	1.8×10^{-5}	$\text{C}_2\text{H}_3\text{O}_2^-$	5.6×10^{-10}
H_2CO_3	4.3×10^{-7}	HCO_3^-	2.3×10^{-8}
NH_4^+	5.6×10^{-10}	NH_3	1.8×10^{-5}
HCO_3^-	5.6×10^{-11}	CO_3^{2-}	1.8×10^{-4}
OH^-	(Negligible acidity)	O^{2-}	(Strong base)

values for the anions of weak acids because they can be readily calculated from the tabulated K_a values for their conjugate acids.

If you look up the values for acid- or base-dissociation constants in a chemistry handbook, you may find them expressed as $\text{p}K_a$ or $\text{p}K_b$ (that is, $-\log K_a$ or $-\log K_b$) (Section 16.4). Equation 16.40 can be written in terms of $\text{p}K_a$ and $\text{p}K_b$ by taking the negative logarithm of both sides:

$$\text{p}K_a + \text{p}K_b = \text{p}K_w = 14.00 \quad \text{at } 25^\circ\text{C} \quad [16.41]$$

▲ GIVE IT SOME THOUGHT

What is the $\text{p}K_a$ value for HF? What is the $\text{p}K_b$ value for F^- ?

CHEMISTRY PUT TO WORK

Amines and Amine Hydrochlorides

Many low-molecular-weight amines have a fishy odor. Amines and NH_3 are produced by the anaerobic (absence of O_2) decomposition of dead animal or plant matter. Two such amines with very disagreeable odors are $\text{H}_2\text{N}(\text{CH}_2)_4\text{NH}_2$, *putrescine*, and

$\text{H}_2\text{N}(\text{CH}_2)_5\text{NH}_2$, *cadaverine*.

Many drugs, including quinine, codeine, caffeine, and amphetamine, are amines. Like other amines, these substances are weak bases; the amine nitrogen is readily protonated upon treatment with an acid. The resulting products are called *acid salts*. If we use A as the abbreviation for an amine, the acid salt formed by reaction with hydrochloric acid can be written AH^+Cl^- . It can also be written as $\text{A}\cdot\text{HCl}$ and referred to as a hydrochloride. Amphetamine hydrochloride, for example, is the acid salt formed by treating amphetamine with HCl:

Acid salts are much less volatile, more stable, and generally more water soluble than the corresponding amines. For this reason, many drugs that are amines are sold and administered as acid salts. Some examples of over-the-counter medications that contain amine hydrochlorides as active ingredients are shown in ▼ FIGURE 16.14.

RELATED EXERCISES: 16.75, 16.76, 16.104, 16.113, and 16.122

◀ FIGURE 16.14 Some over-the-counter medications in which an amine hydrochloride is a major active ingredient.

SAMPLE EXERCISE 16.17 Calculating K_a or K_b for a Conjugate Acid-Base Pair

Calculate (a) K_b for the fluoride ion, (b) K_a for the ammonium ion.

SOLUTION

Analyze We are asked to determine dissociation constants for F^- , the conjugate base of HF, and NH_4^+ , the conjugate acid of NH_3 .

Plan We can use the tabulated K values for HF and NH_3 and the relationship between K_a and K_b to calculate the ionization constants for their conjugates, F^- and NH_4^+ .

Solve

(a) For the weak acid HF, Table 16.2 and Appendix D give $K_a = 6.8 \times 10^{-4}$. We can use Equation 16.40 to calculate K_b for the conjugate base, F^- :

$$K_b = \frac{K_w}{K_a} = \frac{1.0 \times 10^{-14}}{6.8 \times 10^{-4}} = 1.5 \times 10^{-11}$$

(b) For NH_3 , Table 16.4 and in Appendix D give $K_b = 1.8 \times 10^{-5}$, and this value in Equation 16.40 gives us K_a for the conjugate acid, NH_4^+ :

$$K_a = \frac{K_w}{K_b} = \frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}} = 5.6 \times 10^{-10}$$

Check The respective K values for F^- and NH_4^+ are listed in Table 16.5, where we see that the values calculated here agree with those in Table 16.5.

PRACTICE EXERCISE

- (a) Which of these anions has the largest base-dissociation constant: NO_2^- , PO_4^{3-} , or N_3^- ?
 (b) The base quinoline has the structure

Its conjugate acid is listed in handbooks as having a pK_a of 4.90. What is the base-dissociation constant for quinoline?

Answers: (a) PO_4^{3-} ($K_b = 2.4 \times 10^{-2}$), (b) $K_b = 7.9 \times 10^{-10}$

16.9 ACID-BASE PROPERTIES OF SALT SOLUTIONS

Even before you began this chapter, you were undoubtedly aware of many substances that are acidic, such as HNO_3 , HCl , and H_2SO_4 , and others that are basic, such as $NaOH$ and NH_3 . However, our discussion up to this point in the chapter has indicated that ions can also exhibit acidic or basic properties. For example, we calculated K_a for NH_4^+ and K_b for F^- in Sample Exercise 16.17. Such behavior implies that salt solutions can be acidic or basic. Before proceeding with further discussions of acids and bases, let's examine the way dissolved salts can affect pH.

Because nearly all salts are strong electrolytes, we can assume that any salt dissolved in water is completely dissociated. Consequently, the acid-base properties of salt solutions are due to the behavior of the cations and anions. Many ions react with water to generate $H^+(aq)$ or $OH^-(aq)$ ions. This type of reaction is often called **hydrolysis**. The pH of an aqueous salt solution can be predicted qualitatively by considering the salt's cations and anions.

An Anion's Ability to React with Water

In general, an anion X^- in solution can be considered the conjugate base of an acid. For example, Cl^- is the conjugate base of HCl , and CH_3COO^- is the conjugate base of CH_3COOH . Whether or not an anion reacts with water to produce hydroxide ions depends on the strength of the anion's conjugate acid. To identify the acid and assess its strength, we add a proton to the anion's formula. If the acid HX determined in this way is one of the seven strong acids listed on page 664, the anion has a negligible tendency to abstract protons from water and does not affect the pH of the solution. The presence of

Cl^- in an aqueous solution, for example, does not result in the production of any OH^- and does not affect the pH. Thus, Cl^- is always a spectator ion in acid–base chemistry.

If HX is *not* one of the seven strong acids, it is a weak acid. In this case, the conjugate base X^- is a weak base and it reacts to a small extent with water to produce the weak acid and hydroxide ions:

The OH^- ion generated in this way increases the pH of the solution, making it basic. Acetate ion, for example, being the conjugate base of a weak acid, reacts with water to produce acetic acid and hydroxide ions, thereby increasing the pH of the solution:

GIVE IT SOME THOUGHT

What effect will NO_3^- ions have on the pH of a solution? What effect will CO_3^{2-} ions have?

The situation is more complicated for salts containing anions that have ionizable protons, such as HSO_3^- . These salts are amphiprotic (Section 16.2), and how they behave in water is determined by the relative magnitudes of K_a and K_b for the ion, as shown in Sample Exercise 16.19. If $K_a > K_b$, the ion causes the solution to be acidic. If $K_b > K_a$, the solution is made basic by the ion.

A Cation's Ability to React with Water

Polyatomic cations containing one or more protons can be considered the conjugate acids of weak bases. The NH_4^+ ion, for example, is the conjugate acid of the weak base NH_3 . Thus, NH_4^+ is a weak acid and will donate a proton to water, producing hydronium ions and thereby lowering the pH:

Many metal ions react with water to decrease the pH of an aqueous solution. This effect is most pronounced for small, highly charged cations like Fe^{3+} and Al^{3+} , as illustrated by the K_a values for metal cations in  TABLE 16.6. A comparison of Fe^{2+} and Fe^{3+} values in the table illustrates how acidity increases as ionic charge increases.

Notice that K_a values for the 3+ ions in Table 16.6 are comparable to the values for familiar weak acids, such as acetic acid ($K_a = 1.8 \times 10^{-5}$). The ions of alkali and alkaline earth metals, being relatively large and not highly charged, do not react with water and therefore do not affect pH. Note that these are the same cations found in the strong bases (Section 16.5). The different tendencies of four cations to lower the pH of a solution are illustrated in  FIGURE 16.15.

TABLE 16.6 • Acid-Dissociation Constants for Metal Cations in Aqueous Solution at 25 °C

Cation	K_a
Fe^{2+}	3.2×10^{-10}
Zn^{2+}	2.5×10^{-10}
Ni^{2+}	2.5×10^{-11}
Fe^{3+}	6.3×10^{-3}
Cr^{3+}	1.6×10^{-4}
Al^{3+}	1.4×10^{-5}

 **FIGURE 16.15** Effect of cations on solution pH. The pH values of 1.0 M solutions of four nitrate salts are estimated using acid–base indicators.

▲ FIGURE 16.16 A hydrated Fe^{3+} ion acts as an acid by donating an H^+ to a free H_2O molecule, forming H_3O^+ .

The mechanism by which metal ions produce acidic solutions is shown in **▲ FIGURE 16.16**. Because metal ions are positively charged, they attract the unshared electron pairs of water molecules and become hydrated. ∞ (Section 13.1) The larger the charge on the metal ion, the stronger the interaction between the ion and the oxygen of its hydrating water molecules. As the strength of this interaction increases, the $\text{O}-\text{H}$ bonds in the hydrating water molecules become weaker. This facilitates transfer of protons from the hydration water molecules to solvent water molecules.

Combined Effect of Cation and Anion in Solution

To determine whether a salt forms an acidic, a basic, or a neutral solution when dissolved in water, we must consider the action of both cation and anion. There are four possible combinations.

1. If the salt contains an anion that does not react with water and a cation that does not react with water, we expect the pH to be neutral. Such is the case when the anion is a conjugate base of a strong acid and the cation is either from group 1A or one of the heavier members of group 2A (Ca^{2+} , Sr^{2+} , and Ba^{2+}). *Examples:* NaCl , $\text{Ba}(\text{NO}_3)_2$, RbClO_4 .
2. If the salt contains an anion that reacts with water to produce hydroxide ions and a cation that does not react with water, we expect the pH to be basic. Such is the case when the anion is the conjugate base of a weak acid and the cation is either from group 1A or one of the heavier members of group 2A (Ca^{2+} , Sr^{2+} , and Ba^{2+}). *Examples:* NaClO , RbF , BaSO_3 .
3. If the salt contains a cation that reacts with water to produce hydronium ions and an anion that does not react with water, we expect the pH to be acidic. Such is the case when the cation is a conjugate acid of a weak base or a small cation with a charge of $2+$ or greater. *Examples:* NH_4NO_3 , AlCl_3 , $\text{Fe}(\text{NO}_3)_3$.
4. If the salt contains an anion and a cation *both* capable of reacting with water, both hydroxide ions and hydronium ions are produced. Whether the solution is basic, neutral, or acidic depends on the relative abilities of the ions to react with water. *Examples:* NH_4ClO , $\text{Al}(\text{CH}_3\text{COO})_3$, CrF_3 .

SAMPLE EXERCISE 16.18 Determining Whether Salt Solutions Are Acidic, Basic, or Neutral

Determine whether aqueous solutions of each of these salts are acidic, basic, or neutral: (a) $\text{Ba}(\text{CH}_3\text{COO})_2$, (b) NH_4Cl , (c) $\text{CH}_3\text{NH}_3\text{Br}$, (d) KNO_3 , (e) $\text{Al}(\text{ClO}_4)_3$.

SOLUTION

Analyze We are given the chemical formulas of five ionic compounds (salts) and asked whether their aqueous solutions will be acidic, basic, or neutral.

Plan We can determine whether a solution of a salt is acidic, basic, or neutral by identifying the ions in solution and by assessing how each ion will affect the pH.

Solve

(a) This solution contains barium ions and acetate ions. The cation is an ion of a heavy alkaline earth metal and will therefore not affect the pH. The anion, CH_3COO^- , is the conjugate base of the weak acid CH_3COOH and will hydrolyze to produce OH^- ions, thereby making the solution basic (combination 2).

(b) In this solution, NH_4^+ is the conjugate acid of a weak base (NH_3) and is therefore acidic. Cl^- is the conjugate base of a strong acid (HCl) and therefore has no influence on the pH of the solution. Because the solution contains an ion that is acidic (NH_4^+) and one that has no influence on pH (Cl^-), the solution of NH_4Cl will be acidic (combination 3).

(c) Here CH_3NH_3^+ is the conjugate acid of a weak base (CH_3NH_2 , an amine) and is therefore acidic, and Br^- is the conjugate base of a strong acid (HBr) and therefore pH neutral. Because the solution contains one ion that is acidic and one that has no influence on pH, the solution of $\text{CH}_3\text{NH}_3\text{Br}$ will be acidic (combination 3).

(d) This solution contains the K^+ ion, which is a cation of group 1A, and the NO_3^- ion, which is the conjugate base of the strong acid HNO_3 . Neither of the ions will react with water to any appreciable extent, making the solution neutral (combination 1).

(e) This solution contains Al^{3+} and ClO_4^- ions. Cations, such as Al^{3+} , that have a charge of 3+ or higher are acidic. The ClO_4^- ion is the conjugate base of a strong acid (HClO_4) and therefore does not affect pH. Thus, the solution of $\text{Al}(\text{ClO}_4)_3$ will be acidic (combination 3).

PRACTICE EXERCISE

Indicate which salt in each of the following pairs forms the more acidic (or less basic) 0.010 M solution: (a) NaNO_3 or $\text{Fe}(\text{NO}_3)_3$, (b) KBr or KBrO , (c) $\text{CH}_3\text{NH}_3\text{Cl}$ or BaCl_2 , (d) NH_4NO_2 or NH_4NO_3 .

Answers: (a) $\text{Fe}(\text{NO}_3)_3$, (b) KBr , (c) $\text{CH}_3\text{NH}_3\text{Cl}$, (d) NH_4NO_3

SAMPLE EXERCISE 16.19 Predicting Whether the Solution of an Amphiprotic Anion Is Acidic or Basic

Predict whether the salt Na_2HPO_4 forms an acidic solution or a basic solution when dissolved in water.

SOLUTION

Analyze We are asked to predict whether a solution of Na_2HPO_4 is acidic or basic. This substance is an ionic compound composed of Na^+ and HPO_4^{2-} ions.

Plan We need to evaluate each ion, predicting whether it is acidic or basic. Because Na^+ is a cation of group 1A, it has no influence on pH. Thus, our analysis of whether the solution is acidic or basic must focus on the behavior of the HPO_4^{2-} ion. We need to consider the fact that HPO_4^{2-} can act as either an acid or a base:

Of these two reactions, the one with the larger equilibrium constant determines whether the solution is acidic or basic.

Solve The value of K_a for Equation 16.45 is 4.2×10^{-13} (Table 16.3). For Equation 16.46, we must calculate K_b for the base HPO_4^{2-} from the value of K_a for its conjugate acid, H_2PO_4^- , and the relationship $K_a \times K_b = K_w$ (Equation 16.40). Using the value $K_a(\text{H}_2\text{PO}_4^-) = 6.2 \times 10^{-8}$ from Table 16.3, we have

$$K_b(\text{HPO}_4^{2-}) \times K_a(\text{H}_2\text{PO}_4^-) = K_w = 1.0 \times 10^{-14}$$

$$K_b(\text{HPO}_4^{2-}) = \frac{1.0 \times 10^{-14}}{6.2 \times 10^{-8}} = 1.6 \times 10^{-7}$$

This K_b value is more than 10^5 times larger than K_a for HPO_4^{2-} ; thus, the reaction in Equation 16.46 predominates over that in Equation 16.45, and the solution is basic.

PRACTICE EXERCISE

Predict whether the dipotassium salt of citric acid ($\text{K}_2\text{HC}_6\text{H}_5\text{O}_7$) forms an acidic or basic solution in water (see Table 16.3 for data).

Answer: acidic

16.10 ACID–BASE BEHAVIOR AND CHEMICAL STRUCTURE

When a substance is dissolved in water, it may behave as an acid, behave as a base, or exhibit no acid–base properties. How does the chemical structure of a substance determine which of these behaviors is exhibited by the substance? For example, why do some substances that contain OH groups behave as bases, releasing OH^- ions into solution, whereas others behave as acids, ionizing to release H^+ ions? In this section we discuss briefly the effects of chemical structure on acid–base behavior.

Factors That Affect Acid Strength

A molecule containing H will act as a proton donor (an acid) only if the H—X bond is polarized in this way:

In ionic hydrides, such as NaH, the reverse is true: the H atom possesses a negative charge and behaves as a proton acceptor (a base). Nonpolar H—X bonds, such as the H—C bond in CH_4 , produce neither acidic nor basic aqueous solutions.

A second factor that helps determine whether a molecule containing an H—X bond will donate a proton is the strength of the bond. Very strong bonds are less easily broken than weaker ones. This factor is important, for example, in the hydrogen halides. The H—F bond is the most polar H—X bond. You therefore might expect HF to be a very strong acid if bond polarity were all that mattered. However, the H—X bond strength increases as you move up the group: 299 kJ/mol in HI, 366 kJ/mol in HBr, 431 kJ/mol in HCl, and 567 kJ/mol in HF. Because HF has the highest bond strength among the hydrogen halides, it is a weak acid, whereas all the other hydrogen halides are strong acids in water.

A third factor that affects the ease with which a hydrogen atom ionizes from HX is the stability of the conjugate base, X^- . In general, the greater the stability of the conjugate base, the stronger the acid.

The strength of an acid is often a combination of all three factors.

Binary Acids

For a series of binary acids HX in which X represents members of the same *group* in the periodic table, the strength of the H—X bond is generally the most important factor determining acid strength. The strength of an H—X bond tends to decrease as the element X increases in size. As a result, the bond strength decreases and acidity increases down a group. Thus, HCl is a stronger acid than HF, and H_2S is a stronger acid than H_2O .

Bond polarity is the major factor determining acidity for binary acids HX when X represents members of the same *period*. Thus, acidity increases as the electronegativity of the element X increases, as it generally does moving from left to right across a period. For example, the difference in acidity of the period 2 elements is $\text{CH}_4 < \text{NH}_3 \ll \text{H}_2\text{O} < \text{HF}$. Because the C—H bond is essentially nonpolar, CH_4 shows no tendency to form H^+ and CH_3^- ions. Although the N—H bond is polar, NH_3 has a nonbonding pair of electrons on the nitrogen atom that dominates its chemistry, so NH_3 acts as a base rather than an acid.

4A	5A	6A	7A
CH₄ Neither acid nor base	NH₃ Weak base $K_b = 1.8 \times 10^{-5}$	H₂O	HF Weak acid $K_a = 6.8 \times 10^{-4}$
SiH₄ Neither acid nor base	PH₃ Very weak base $K_b = 4 \times 10^{-28}$	H₂S Weak acid $K_a = 9.5 \times 10^{-8}$	HCl Strong acid
		H₂Se Weak acid $K_a = 1.3 \times 10^{-4}$	HBr Strong acid

Increasing acid strength

Increasing acid strength

► **FIGURE 16.17** Trends in acid strength for the binary hydrides of periods 2–4.

The periodic trends in the acid strengths of binary compounds of hydrogen and the nonmetals of periods 2 and 3 are summarized in ▲ **FIGURE 16.17**.

▲ GIVE IT SOME THOUGHT

What is the major factor determining the increase in acidity of binary acids going down a group? What is the major factor going across a period?

Oxyacids

Many common acids, such as sulfuric acid, contain one or more O—H bonds:

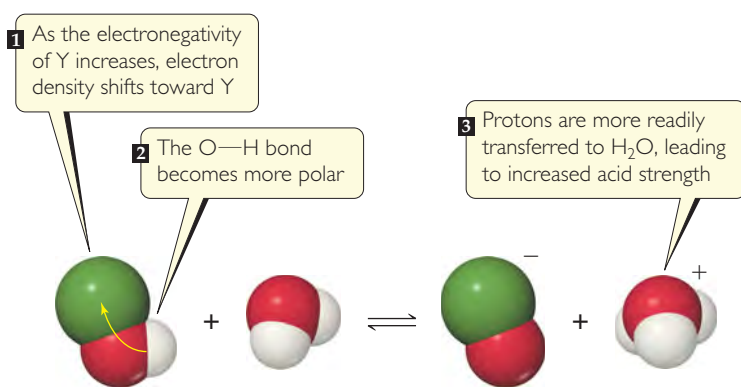

Acids in which OH groups and possibly additional oxygen atoms are bound to a central atom are called **oxyacids**. At first it may seem confusing that the OH group, which we know behaves as a base, is also present in some acids. Let's take a closer look at what factors determine whether a given OH group behaves as a base or as an acid.

Consider an OH group bound to some atom Y, which might in turn have other groups attached to it:

At one extreme, Y might be a metal, such as Na or Mg. Because of the low electronegativity of metals, the pair of electrons shared between Y and O is completely transferred to oxygen, and an ionic compound containing OH^- is formed. Such compounds are therefore sources of OH^- ions and behave as bases, as in NaOH and $\text{Mg}(\text{OH})_2$.

When Y is a nonmetal, the bond to O is covalent and the substance does not readily lose OH^- . Instead, these compounds are either acidic or neutral. *Generally, as the electronegativity of Y increases, so does the acidity of the substance.* This happens for two reasons: First, as electron density is drawn toward Y, the O—H bond becomes weaker and more polar, thereby favoring loss of H^+ . Second, because the conjugate base of any acid YO is usually an anion, its stability generally increases as the electronegativity of

Substance	Y—OH	Electronegativity of Y	Dissociation constant
Hypochlorous acid	Cl—OH	3.0	$K_a = 3.0 \times 10^{-8}$
Hypobromous acid	Br—OH	2.8	$K_a = 2.5 \times 10^{-9}$
Hypoiodous acid	I—OH	2.5	$K_a = 2.3 \times 10^{-11}$
Water	H—OH	2.1	$K_w = 1.0 \times 10^{-14}$

◀ **FIGURE 16.18** Acidity of the hypohalous oxyacids (YOH) as a function of electronegativity of Y.

Y increases. This trend is illustrated by the K_a values of the hypohalous acids (YOH acids where Y is a halide ion), which decrease as the electronegativity of the halogen atom decreases (▲ **FIGURE 16.18**).

Many oxyacids contain additional oxygen atoms bonded to the central atom Y. These atoms pull electron density from the O—H bond, further increasing its polarity. Increasing the number of oxygen atoms also helps stabilize the conjugate base by increasing its ability to “spread out” its negative charge. Thus, *the strength of an acid increases as additional electronegative atoms bond to the central atom Y*. For example, the strength of the chlorine oxyacids (Y = Cl) steadily increases as O atoms are added:

Because the oxidation number of Y increases as the number of attached O atoms increases, this correlation can be stated in an equivalent way: In a series of oxyacids, the acidity increases as the oxidation number of the central atom increases.

▲ GIVE IT SOME THOUGHT

Which acid has the larger acid-dissociation constant, HIO_2 or HBrO_3 ?

SAMPLE EXERCISE 16.20 Predicting Relative Acidities from Composition and Structure

Arrange the compounds in each series in order of increasing acid strength: (a) AsH_3 , HBr , KH , H_2Se ; (b) H_2SO_4 , H_2SeO_3 , H_2SeO_4 .

SOLUTION

Analyze We are asked to arrange two sets of compounds in order from weakest acid to strongest acid. In (a), the substances are binary compounds containing H, and in (b) the substances are oxyacids.

Plan For the binary compounds, we will consider the electronegativities of As, Br, K, and Se relative to the electronegativity of H. The higher the electronegativity of these atoms, the higher the partial positive charge on H and so the more acidic the compound.

For the oxyacids, we will consider both the electronegativities of the central atom and the number of oxygen atoms bonded to the central atom.

Solve

(a) Because K is on the left side of the periodic table, it has a very low electronegativity (0.8, from Figure 8.7). As a result, the hydrogen in KH carries a negative charge. Thus, KH should be the least acidic (most basic) compound in the series.

Arsenic and hydrogen have similar electronegativities, 2.0 and 2.1, respectively. This means that the As—H bond is nonpolar, and so AsH₃ has little tendency to donate a proton in aqueous solution.

The electronegativity of Se is 2.4, and that of Br is 2.8. Consequently, the H—Br bond is more polar than the H—Se bond, giving HBr the greater tendency to donate a proton. (This expectation is confirmed by Figure 16.17, where we see that H₂Se is a weak acid and HBr a strong acid.) Thus, the order of increasing acidity is KH < AsH₃ < H₂Se < HBr.

(b) The acids H₂SO₄ and H₂SeO₄ have the same number of O atoms and the same number of OH groups. In such cases, the acid strength increases with increasing electronegativity of the central atom. Because S is slightly more electronegative than Se (2.5 vs 2.4), we predict that H₂SO₄ is more acidic than H₂SeO₄.

For acids with the same central atom, the acidity increases as the number of oxygen atoms bonded to the central atom increases. Thus, H₂SeO₄ should be a stronger acid than H₂SeO₃. We predict the order of increasing acidity to be H₂SeO₃ < H₂SeO₄ < H₂SO₄.

PRACTICE EXERCISE

In each pair, choose the compound that give the more acidic (or less basic) solution: (a) HBr, HF; (b) PH₃, H₂S; (c) HNO₂, HNO₃; (d) H₂SO₃, H₂SeO₃.

Answers: (a) HBr, (b) H₂S, (c) HNO₃, (d) H₂SO₃

Carboxylic Acids

Another large group of acids is illustrated by acetic acid, a weak acid ($K_a = 1.8 \times 10^{-5}$):

The portion of the structure shown in red is called the *carboxyl group*, which is often written COOH. Thus, the chemical formula of acetic acid is written as CH₃COOH, where only the hydrogen atom in the carboxyl group can be ionized. Acids that contain a carboxyl group are called **carboxylic acids**, and they form the largest category of organic acids. Formic acid and benzoic acid are further examples of this large and important category of acids:

Two factors contribute to the acidic behavior of carboxylic acids. First, the additional oxygen atom attached to the carbon of the carboxyl group draws electron density from the O—H bond, increasing its polarity and helping to stabilize the conjugate base. Second, the conjugate base of a carboxylic acid (a *carboxylate anion*) can exhibit resonance \leftrightarrow (Section 8.6), which contributes to the stability of the anion by spreading the negative charge over several atoms:

CHEMISTRY AND LIFE

THE AMPHIPROTIC BEHAVIOR OF AMINO ACIDS

The general structure of *amino acids*, the building blocks of proteins, is

where different amino acids have different R groups attached to the central carbon atom. For example, in *glycine*, the simplest amino acid, R is a hydrogen atom, and in *alanine* R is a CH₃ group:

Amino acids contain a carboxyl group and can therefore serve as acids. They also contain an NH₂ group, characteristic of amines (Section 16.7), and thus they can also act as bases. Amino acids, therefore, are amphoteric. For glycine, we might expect the acid and base reactions with water to be

The pH of a solution of glycine in water is about 6.0, indicating that it is a slightly stronger acid than base. The acid–base chemistry of amino acids is more complicated than shown in Equations 16.47 and 16.48, however. Because the COOH group can act as an acid and the NH₂ group can act as a base, amino acids undergo a “self-contained” Brønsted–Lowry acid–base reaction in which the proton of the carboxyl group is transferred to the basic nitrogen atom:

Although the form of the amino acid on the right in this equation is electrically neutral overall, it has a positively charged end and a negatively charged end. A molecule of this type is called a *zwitterion* (German for “hybrid ion”).

Do amino acids exhibit any properties indicating that they behave as zwitterions? If so, their behavior should be similar to that of ionic substances. ∞ (Section 8.2) Crystalline amino acids have relatively high melting points, usually above 200°C, which is characteristic of ionic solids. Amino acids are far more soluble in water than in nonpolar solvents. In addition, the dipole moments of amino acids are large, consistent with a large separation of charge in the molecule. Thus, the ability of amino acids to act simultaneously as acids and bases has important effects on their properties.

RELATED EXERCISE: 16.113

GIVE IT SOME THOUGHT

What group of atoms is present in all carboxylic acids?

16.11 LEWIS ACIDS AND BASES

For a substance to be a proton acceptor (a Brønsted–Lowry base), it must have an unshared pair of electrons for binding the proton, as, for example, in NH₃. Using Lewis structures, we can write the reaction between H⁺ and NH₃ as

G. N. Lewis was the first to notice this aspect of acid–base reactions. He proposed a definition of acid and base that emphasizes the shared electron pair: A **Lewis acid** is an electron-pair acceptor, and a **Lewis base** is an electron-pair donor.

Every base that we have discussed thus far—whether OH[−], H₂O, an amine, or an anion—is an electron-pair donor. Everything that is a base in the Brønsted–Lowry sense (a proton acceptor) is also a base in the Lewis sense (an electron-pair donor). In the Lewis theory, however, a base can donate its electron pair to something other than H⁺.

The Lewis definition therefore greatly increases the number of species that can be considered acids; in other words, H^+ is a Lewis acid but not the only one. For example, the reaction between NH_3 and BF_3 occurs because BF_3 has a vacant orbital in its valence shell. ∞ (Section 8.7) It therefore acts as an electron-pair acceptor (a Lewis acid) toward NH_3 , which donates the electron pair:

GIVE IT SOME THOUGHT

What feature must any molecule or ion have in order to act as a Lewis base?

Our emphasis throughout this chapter has been on water as the solvent and on the proton as the source of acidic properties. In such cases we find the Brønsted–Lowry definition of acids and bases to be the most useful. In fact, when we speak of a substance as being acidic or basic, we are usually thinking of aqueous solutions and using these terms in the Arrhenius or Brønsted–Lowry sense. The advantage of the Lewis definitions of acid and base is that they allow us to treat a wider variety of reactions, including those that do not involve proton transfer, as acid–base reactions. To avoid confusion, a substance such as BF_3 is rarely called an acid unless it is clear from the context that we are using the term in the sense of the Lewis definition. Instead, substances that function as electron-pair acceptors are referred to explicitly as “Lewis acids.”

Lewis acids include molecules that, like BF_3 , have an incomplete octet of electrons. In addition, many simple cations can function as Lewis acids. For example, Fe^{3+} interacts strongly with cyanide ions to form the ferricyanide ion:

The Fe^{3+} ion has vacant orbitals that accept the electron pairs donated by the cyanide ions. (We will learn more in Chapter 23 about just which orbitals are used by the Fe^{3+} ion.) The metal ion is highly charged, too, which contributes to the interaction with CN^- ions.

Some compounds containing multiple bonds can behave as Lewis acids. For example, the reaction of carbon dioxide with water to form carbonic acid (H_2CO_3) can be pictured as an attack by a water molecule on CO_2 , in which the water acts as an electron-pair donor and the CO_2 as an electron-pair acceptor:

One electron pair of one of the carbon–oxygen double bonds is moved onto the oxygen, leaving a vacant orbital on the carbon, which means the carbon can accept an electron pair donated by H_2O . The initial acid–base product rearranges by transferring a proton from the water oxygen to a carbon dioxide oxygen, forming carbonic acid.

The hydrated cations we encountered in Section 16.9, such as $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$ in Figure 16.16, form through the reaction between the cation acting as a Lewis acid and the water molecules acting as Lewis bases. When a water molecule interacts with the positively charged metal ion, electron density is drawn from the oxygen (► FIGURE 16.19). This flow of electron density causes the O–H bond to become more polarized; as a result, water molecules bound to the metal ion are more acidic than those in the bulk solvent. This effect becomes more pronounced as the charge of the cation increases, which explains why 3+ cations are much more acidic than cations with smaller charges.

◀ **FIGURE 16.19** The acidity of a hydrated cation depends on cation charge.

SAMPLE INTEGRATIVE EXERCISE Putting Concepts Together

Phosphorous acid (H_3PO_3) has the Lewis structure

(a) Explain why H_3PO_3 is diprotic and not triprotic. (b) A 25.0-mL sample of an H_3PO_3 solution titrated with 0.102 M NaOH requires 23.3 mL of NaOH to neutralize both acidic protons. What is the molarity of the H_3PO_3 solution? (c) The original solution from part (b) has a pH of 1.59. Calculate the percent ionization and K_{a1} for H_3PO_3 , assuming that $K_{a1} \gg K_{a2}$. (d) How does the osmotic pressure of a 0.050 M solution of HCl compare qualitatively with that of a 0.050 M solution of H_3PO_3 ? Explain.

SOLUTION

We will use what we have learned about molecular structure and its impact on acidic behavior to answer part (a). We will then use stoichiometry and the relationship between pH and $[\text{H}^+]$ to answer parts (b) and (c). Finally, we will consider percent ionization in order to compare the osmotic pressure of the two solutions in part (d).

(a) Acids have polar H—X bonds. From Figure 8.7 we see that the electronegativity of H is 2.1 and that of P is also 2.1. Because the two elements have the same electronegativity, the H—P bond is nonpolar. ∞ (Section 8.4) Thus, this H cannot be acidic. The other two H atoms, however, are bonded to O, which has an electronegativity of 3.5. The H—O bonds are, therefore, polar with H having a partial positive charge. These two H atoms are consequently acidic.

(b) The chemical equation for the neutralization reaction is

From the definition of molarity, $M = \text{mol/L}$, we see that moles = $M \times L$. ∞ (Section 4.5) Thus, the number of moles of NaOH added to the solution is

$$(0.0233 \text{ L})(0.102 \text{ mol/L}) = 2.38 \times 10^{-3} \text{ mol NaOH}$$

The balanced equation indicates that 2 mol of NaOH is consumed for each mole of H_3PO_3 . Thus, the number of moles of H_3PO_3 in the sample is

$$(2.38 \times 10^{-3} \text{ mol NaOH}) \left(\frac{1 \text{ mol H}_3\text{PO}_3}{2 \text{ mol NaOH}} \right) = 1.19 \times 10^{-3} \text{ mol H}_3\text{PO}_3$$

The concentration of the H_3PO_3 solution, therefore, equals $(1.19 \times 10^{-3} \text{ mol}) / (0.0250 \text{ L}) = 0.0476 \text{ M}$.

(c) From the pH of the solution, 1.59, we can calculate $[H^+]$ at equilibrium:

$$[H^+] = \text{antilog}(-1.59) = 10^{-1.59} = 0.026 \text{ M (two significant figures)}$$

Because $K_{a1} \gg K_{a2}$, the vast majority of the ions in solution are from the first ionization step of the acid.

Because one $H_2PO_3^-$ ion forms for each H^+ ion formed, the equilibrium concentrations of H^+ and $H_2PO_3^-$ are equal: $[H^+] = [H_2PO_3^-] = 0.026 \text{ M}$. The equilibrium concentration of H_3PO_3 equals the initial concentration minus the amount that ionizes to form H^+ and $H_2PO_3^-$: $[H_3PO_3] = 0.0476 \text{ M} - 0.026 \text{ M} = 0.022 \text{ M}$ (two significant figures). These results can be tabulated as follows:

	$H_3PO_3(aq)$	\rightleftharpoons	$H^+(aq)$	+	$H_2PO_3^-(aq)$
Initial	0.0476 M		0		0
Change	-0.026 M		+0.026 M		+0.026 M
Equilibrium	0.022 M		0.026 M		0.026 M

The percent ionization is

$$\text{percent ionization} = \frac{[H^+]_{\text{equilibrium}}}{[H_3PO_3]_{\text{initial}}} \times 100\% = \frac{0.026 \text{ M}}{0.0476 \text{ M}} \times 100\% = 55\%$$

The first acid-dissociation constant is

$$K_{a1} = \frac{[H^+][H_2PO_3^-]}{[H_3PO_3]} = \frac{(0.026)(0.026)}{0.022} = 0.031$$

(d) Osmotic pressure is a colligative property and depends on the total concentration of particles in solution. ∞ (Section 13.5) Because HCl is a strong acid, a 0.050 M solution will contain 0.050 M $H^+(aq)$ and 0.050 M $Cl^-(aq)$, or a total of 0.100 mol/L of particles. Because H_3PO_3 is a weak acid, it ionizes to a lesser extent than HCl and, hence, there are fewer particles in the H_3PO_3 solution. As a result, the H_3PO_3 solution will have the lower osmotic pressure.

CHAPTER SUMMARY AND KEY TERMS

SECTION 16.1 Acids and bases were first recognized by the properties of their aqueous solutions. For example, acids turn litmus red, whereas bases turn litmus blue. Arrhenius recognized that the properties of acidic solutions are due to $H^+(aq)$ ions and those of basic solutions are due to $OH^-(aq)$ ions.

SECTION 16.2 The Brønsted–Lowry concept of acids and bases is more general than the Arrhenius concept and emphasizes the transfer of a proton (H^+) from an acid to a base. The H^+ ion, which is merely a proton with no surrounding valence electrons, is strongly bound to water. For this reason, the **hydronium ion**, $H_3O^+(aq)$, is often used to represent the predominant form of H^+ in water instead of the simpler $H^+(aq)$.

A **Brønsted–Lowry acid** is a substance that donates a proton to another substance; a **Brønsted–Lowry base** is a substance that accepts a proton from another substance. Water is an **amphiprotic** substance, one that can function as either a Brønsted–Lowry acid or base, depending on the substance with which it reacts.

The **conjugate base** of a Brønsted–Lowry acid is the species that remains when a proton is removed from the acid. The **conjugate acid** of a Brønsted–Lowry base is the species formed by adding a proton to the base. Together, an acid and its conjugate base (or a base and its conjugate acid) are called a **conjugate acid–base pair**.

The acid–base strengths of conjugate acid–base pairs are related: The stronger an acid, the weaker is its conjugate base; the weaker an acid, the stronger is its conjugate base. In every acid–base reaction, the position of the equilibrium favors the transfer of the proton from the stronger acid to the stronger base.

SECTION 16.3 Water ionizes to a slight degree, forming $H^+(aq)$ and $OH^-(aq)$. The extent of this **autoionization** is expressed by the **ion-product constant** for water: $K_w = [H^+][OH^-] = 1.0 \times 10^{-14}$ (25 °C). This relationship describes both pure water and aqueous solutions. The K_w expression indicates that the product of $[H^+]$ and $[OH^-]$ is a constant. Thus, as $[H^+]$ increases, $[OH^-]$ decreases. Acidic solutions are those that contain more $H^+(aq)$ than $OH^-(aq)$, whereas basic solutions contain more $OH^-(aq)$ than $H^+(aq)$.

SECTION 16.4 The concentration of $H^+(aq)$ can be expressed in terms of **pH**: $\text{pH} = -\log[H^+]$. At 25 °C the pH of a neutral solution is 7.00, whereas the pH of an acidic solution is below 7.00, and the pH of a basic solution is above 7.00. The **pX** notation is also used to represent the negative logarithm of other small quantities, as in **pOH** and **pK_w**. The pH of a solution can be measured using a pH meter, or it can be estimated using acid–base indicators.

SECTION 16.5 Strong acids are strong electrolytes, ionizing completely in aqueous solution. The common strong acids are HCl, HBr, HI, HNO_3 , $HClO_3$, $HClO_4$, and H_2SO_4 . The conjugate bases of strong acids have negligible basicity.

Common strong bases are the ionic hydroxides of the alkali metals and the heavy alkaline earth metals.

SECTION 16.6 Weak acids are weak electrolytes; only some of the molecules exist in solution in ionized form. The extent of ionization is expressed by the **acid-dissociation constant**, K_a , which is the equilibrium constant for the reaction $HA(aq) \rightleftharpoons H^+(aq) + A^-(aq)$, which can also be written $HA(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + A^-(aq)$.

The larger the value of K_a , the stronger is the acid. For solutions of the same concentration, a stronger acid also has a larger **percent ionization**. The concentration of a weak acid and its K_a value can be used to calculate the pH of a solution.

Polyprotic acids, such as H_2SO_3 , have more than one ionizable proton. These acids have acid-dissociation constants that decrease in magnitude in the order $K_{a1} > K_{a2} > K_{a3}$. Because nearly all the $\text{H}^+(aq)$ in a polyprotic acid solution comes from the first dissociation step, the pH can usually be estimated satisfactorily by considering only K_{a1} .

SECTION 16.7 Weak bases include NH_3 , **amines**, and the anions of weak acids. The extent to which a weak base reacts with water to generate the corresponding conjugate acid and OH^- is measured by the **base-dissociation constant**, K_b . This is the equilibrium constant for the reaction $\text{B}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{HB}^+(aq) + \text{OH}^-(aq)$, where B is the base.

SECTION 16.8 The relationship between the strength of an acid and the strength of its conjugate base is expressed quantitatively by the equation $K_a \times K_b = K_w$, where K_a and K_b are dissociation constants for conjugate acid–base pairs.

SECTION 16.9 The acid–base properties of salts can be ascribed to the behavior of their respective cations and anions. The reaction of ions with water, with a resultant change in pH, is called **hydrolysis**. The cations of

the alkali metals and the alkaline earth metals as well as the anions of strong acids, such as Cl^- , Br^- , I^- , and NO_3^- , do not undergo hydrolysis. They are always spectator ions in acid–base chemistry.

SECTION 16.10 The tendency of a substance to show acidic or basic characteristics in water can be correlated with its chemical structure. Acid character requires the presence of a highly polar H—X bond. Acidity is also favored when the H—X bond is weak and when the X^- ion is very stable.

For **oxyacids** with the same number of OH groups and the same number of O atoms, acid strength increases with increasing electronegativity of the central atom. For oxyacids with the same central atom, acid strength increases as the number of oxygen atoms attached to the central atom increases. **Carboxylic acids**, which are organic acids containing the COOH group, are the most important class of organic acids. The presence of delocalized pi bonding in the conjugate base is partially responsible for the acidity of these compounds.

SECTION 16.11 The Lewis concept of acids and bases emphasizes the shared electron pair rather than the proton. A **Lewis acid** is an electron-pair acceptor, and a **Lewis base** is an electron-pair donor. The Lewis concept is more general than the Brønsted–Lowry concept because it can apply to cases in which the acid is some substance other than H^+ .

KEY SKILLS

- Define and identify Arrhenius acids and bases. (Section 16.1)
- Understand the nature of the hydrated proton, represented as either $\text{H}^+(aq)$ or $\text{H}_3\text{O}^+(aq)$. (Section 16.2)
- Define and identify Brønsted–Lowry acids and bases and identify conjugate acid–base pairs. (Section 16.2)
- Relate the strength of an acid to the strength of its conjugate base. (Section 16.2)
- Understand how the equilibrium position of a proton-transfer reaction relates the strengths of the acids and bases involved. (Section 16.3)
- Describe the autoionization of water and understand how $[\text{H}_3\text{O}^+]$ and $[\text{OH}^-]$ are related. (Section 16.3)
- Calculate the pH of a solution given $[\text{H}_3\text{O}^+]$ or $[\text{OH}^-]$. (Section 16.4)
- Calculate the pH of a strong acid or strong base given its concentration. (Section 16.5)
- Calculate K_a or K_b for a weak acid or weak base given its concentration and the pH of the solution. (Sections 16.6 and 16.7)
- Calculate the pH of a weak acid or weak base or its percent ionization given its concentration and K_a or K_b . (Sections 16.6 and 16.7)
- Calculate K_b for a weak base given K_a of its conjugate acid, and similarly calculate K_a from K_b . (Section 16.8)
- Predict whether an aqueous solution of a salt will be acidic, basic, or neutral. (Section 16.9)
- Predict the relative strength of a series of acids from their molecular structures. (Section 16.10)
- Define and identify Lewis acids and bases. (Section 16.11)

KEY EQUATIONS

- $K_w = [\text{H}_3\text{O}^+][\text{OH}^-] = [\text{H}^+][\text{OH}^-] = 1.0 \times 10^{-14}$ [16.16] Ion product of water at 25 °C
- $\text{pH} = -\log[\text{H}^+]$ [16.17] Definition of pH
- $\text{pOH} = -\log[\text{OH}^-]$ [16.18] Definition of pOH
- $\text{pH} + \text{pOH} = 14.00$ [16.20] Relationship between pH and pOH
- $K_a = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]}$ or $K_a = \frac{[\text{H}^+][\text{A}^-]}{[\text{HA}]}$ [16.25] Acid dissociation constant for a weak acid, HA
- $\text{Percent ionization} = \frac{[\text{H}^+]_{\text{equilibrium}}}{[\text{HA}]_{\text{initial}}} \times 100\%$ [16.27] Percent ionization of a weak acid
- $K_b = \frac{[\text{BH}^+][\text{OH}^-]}{[\text{B}]}$ [16.34] Base-dissociation constant for a weak base, B
- $K_a \times K_b = K_w$ [16.40] Relationship between acid- and base-dissociation constants of a conjugate acid–base pair

EXERCISES

VISUALIZING CONCEPTS

- 16.1 (a) Identify the Brønsted–Lowry acid and base in the reaction

- (b) Identify the Lewis acid and base in the reaction. [Sections 16.2 and 16.11]

- 16.2 The following diagrams represent aqueous solutions of two monoprotic acids, HA (A = X or Y). The water molecules have been omitted for clarity. (a) Which is the stronger acid, HX or HY? (b) Which is the stronger base, X[−] or Y[−]? (c) If you mix equal concentrations of HX and NaY, will the equilibrium

- lie mostly to the right ($K_c > 1$) or to the left ($K_c < 1$)? [Section 16.2]

- 16.3 The following diagrams represent aqueous solutions of three acids, HX, HY, and HZ. The water molecules have been omitted for clarity, and the hydrated proton is represented as H⁺ rather than H₃O⁺. (a) Which of the acids is a strong acid? Explain. (b) Which acid would have the smallest acid-dissociation constant, K_a ? (c) Which solution would have the highest pH? [Sections 16.5 and 16.6]

- 16.4 In which of the following cases is the approximation that the equilibrium concentration of H⁺(aq) is small relative to the initial concentration of HA likely to be most valid: (a) initial [HA] = 0.100 M and $K_a = 1.0 \times 10^{-6}$, (b) initial [HA] = 0.100 M and $K_a = 1.0 \times 10^{-4}$, (c) initial [HA] = 1.00 M and $K_a = 1.0 \times 10^{-6}$? [Section 16.6]

- 16.5 The indicator methyl orange has been added to both of these solutions. Based on the colors, classify each statement as true or false:

- (a) The pH of solution A is definitely less than 7.00.

- (b) The pH of solution B is definitely greater than 7.00.

- (c) The pH of solution B is greater than that of solution A. [Section 16.4]

Solution A Solution B

- 16.6 (a) Which of these three lines represents the effect of concentration on the percent ionization of a weak acid? (b) Explain in qualitative terms why the curve you chose has the shape it does. [Section 16.6]

- 16.7 Each of the three molecules shown here contains an OH group, but one molecule acts as a base, one as an acid, and the third is neither acid nor base. (a) Which one acts as a base? Why does only this molecule act as a base? (b) Which one acts as an acid? (c) Why is the remaining molecule neither acidic nor basic? [Sections 16.6 and 16.7]

16.8 Which of the following diagrams best represents an aqueous solution of NaF? The water molecules are not shown for clarity. Will this solution be acidic, neutral, or basic? [Section 16.9]

16.9 Consider the molecular models shown here, where X represents a halogen atom. (a) If X is the same atom in both molecules, which one will be more acidic? (b) Does the acidity of each molecule increase or decrease as the electronegativity of the atom X increases? [Section 16.10]

16.10 (a) The following diagram represents the reaction of PCl_4^+ with Cl^- . Draw the Lewis structures for the reactants and products, and identify the Lewis acid and the Lewis base in the reaction.

(b) The following reaction represents a hydrated cation losing a proton. How does the equilibrium constant for the reaction change as the charge of the cation increases? [Sections 16.9 and 16.11]

ARRHENIUS AND BRØNSTED-LOWRY ACIDS AND BASES (sections 16.1 and 16.2)

16.11 Although HCl and H_2SO_4 have very different properties as pure substances, their aqueous solutions possess many common properties. List some general properties of these solutions, and explain their common behavior in terms of the species present.

16.12 Although pure NaOH and NH_3 have very different properties, their aqueous solutions possess many common properties. List some general properties of these solutions, and explain their common behavior in terms of the species present.

16.13 (a) What is the difference between the Arrhenius and the Brønsted-Lowry definitions of an acid? (b) $\text{NH}_3(\text{g})$ and $\text{HCl}(\text{g})$ react to form the ionic solid $\text{NH}_4\text{Cl}(\text{s})$. Which substance is the Brønsted-Lowry acid in this reaction? Which is the Brønsted-Lowry base?

16.14 (a) What is the difference between the Arrhenius and the Brønsted-Lowry definitions of a base? (b) Can a substance behave as an Arrhenius base if it does not contain an OH group? Explain.

16.15 (a) Give the conjugate base of the following Brønsted-Lowry acids: (i) HIO_3 , (ii) NH_4^+ . (b) Give the conjugate acid of the following Brønsted-Lowry bases: (i) O^{2-} , (ii) H_2PO_4^- .

16.16 (a) Give the conjugate base of the following Brønsted-Lowry acids: (i) HCOOH , (ii) HPO_4^{2-} . (b) Give the conjugate acid of the following Brønsted-Lowry bases: (i) SO_4^{2-} , (ii) CH_3NH_2 .

16.17 Designate the Brønsted-Lowry acid and the Brønsted-Lowry base on the left side of each of the following equations, and

also designate the conjugate acid and conjugate base of each on the right side:

16.18 Designate the Brønsted-Lowry acid and the Brønsted-Lowry base on the left side of each equation, and also designate the conjugate acid and conjugate base of each on the right side.

16.19 (a) The hydrogen oxalate ion (HC_2O_4^-) is amphiprotic. Write a balanced chemical equation showing how it acts as an acid toward water and another equation showing how it acts as a base toward water. (b) What is the conjugate acid of HC_2O_4^- ? What is its conjugate base?

16.20 (a) Write an equation for the reaction in which $\text{H}_2\text{C}_6\text{H}_7\text{O}_5^-$ acts as a base in $\text{H}_2\text{O}(\text{l})$. (b) Write an equation for the reaction in which $\text{H}_2\text{C}_6\text{H}_7\text{O}_5^-$ acts as an acid in $\text{H}_2\text{O}(\text{l})$. (c) What is the conjugate acid of $\text{H}_2\text{C}_6\text{H}_7\text{O}_5^-$? What is its conjugate base?

16.21 Label each of the following as being a strong base, a weak base, or a species with negligible basicity. In each case write the formula of its conjugate acid, and indicate whether the conjugate acid is a strong acid, a weak acid, or a species with negligible acidity: (a) CH_3COO^- , (b) HCO_3^- , (c) O^{2-} , (d) Cl^- , (e) NH_3 .

- 16.22** Label each of the following as being a strong acid, a weak acid, or a species with negligible acidity. In each case write the formula of its conjugate base, and indicate whether the conjugate base is a strong base, a weak base, or a species with negligible basicity: (a) HCOOH, (b) H₂, (c) CH₄, (d) HF, (e) NH₄⁺.
- 16.23** (a) Which of the following is the stronger Brønsted–Lowry acid, HBrO or HBr? (b) Which is the stronger Brønsted–Lowry base, F[−] or Cl[−]? Briefly explain your choices.
- 16.24** (a) Which of the following is the stronger Brønsted–Lowry acid, HClO₃ or HClO₂? (b) Which is the stronger Brønsted–Lowry base, HS[−] or HSO₄[−]? Briefly explain your choices.
- 16.25** Predict the products of the following acid–base reactions, and predict whether the equilibrium lies to the left or to the right of the equation:
- (a) O^{2−}(aq) + H₂O(l) ⇌
 (b) CH₃COOH(aq) + HS[−](aq) ⇌
 (c) NO₂[−](aq) + H₂O(l) ⇌
- 16.26** Predict the products of the following acid–base reactions, and predict whether the equilibrium lies to the left or to the right of the equation:
- (a) NH₄⁺(aq) + OH[−](aq) ⇌
 (b) CH₃COO[−](aq) + H₃O⁺(aq) ⇌
 (c) HCO₃[−](aq) + F[−](aq) ⇌

AUTOIONIZATION OF WATER (section 16.3)

- 16.27** If a neutral solution of water, with pH = 7.00, is heated to 50 °C, the pH drops to 6.63. Does this mean that the concentration of [H⁺] is greater than the concentration of [OH[−]]? Explain.
- 16.28** (a) Write a chemical equation that illustrates the autoionization of water. (b) Write the expression for the ion-product constant for water, *K_w*. Why is [H₂O] absent from this expression? (c) A solution is described as basic. What does this statement mean?
- 16.29** Calculate [H⁺] for each of the following solutions, and indicate whether the solution is acidic, basic, or neutral: (a) [OH[−]] = 0.00045 M; (b) [OH[−]] = 8.8 × 10^{−9} M; (c) a solution in which [OH[−]] is 100 times greater than [H⁺].
- 16.30** Calculate [OH[−]] for each of the following solutions, and indicate whether the solution is acidic, basic, or neutral: (a) [H⁺] = 0.0505 M; (b) [H⁺] = 2.5 × 10^{−10} M; (c) a solution in which [H⁺] is 1000 times greater than [OH[−]].
- 16.31** At the freezing point of water (0 °C), *K_w* = 1.2 × 10^{−15}. Calculate [H⁺] and [OH[−]] for a neutral solution at this temperature.
- 16.32** Deuterium oxide (D₂O, where D is deuterium, the hydrogen-2 isotope) has an ion-product constant, *K_w*, of 8.9 × 10^{−16} at 20 °C. Calculate [D⁺] and [OD[−]] for pure (neutral) D₂O at this temperature.

THE pH SCALE (section 16.4)

- 16.33** By what factor does [H⁺] change for a pH change of (a) 2.00 units, (b) 0.50 units?
- 16.34** Consider two solutions, solution A and solution B. [H⁺] in solution A is 250 times greater than that in solution B. What is the difference in the pH values of the two solutions?
- 16.35** (a) If NaOH is added to water, how does [H⁺] change? How does pH change? (b) Use the pH values in Figure 16.5 to estimate the pH of a solution with [H⁺] = 0.0006 M. Is the solution acidic or basic? (c) If the pH of a solution is 5.2, first estimate and then calculate the molar concentrations of H⁺(aq) and OH[−](aq) in the solution.
- 16.36** (a) If HNO₃ is added to water, how does [OH[−]] change? How does pH change? (b) Use the pH values in Figure 16.5 to estimate the pH of a solution with [OH[−]] = 0.014 M. Is the solution acidic or basic? (c) If pH = 6.6, first estimate and then calculate the molar concentrations of H⁺(aq) and OH[−](aq) in the solution.
- 16.37** Complete the following table by calculating the missing entries and indicating whether the solution is acidic or basic.
- 16.38** Complete the following table by calculating the missing entries. In each case indicate whether the solution is acidic or basic.

pH	pOH	[H ⁺]	[OH [−]]	Acidic or basic?
5.25	2.02	4.4 × 10 ^{−10} M	8.5 × 10 ^{−2} M	

- 16.40** Carbon dioxide in the atmosphere dissolves in raindrops to produce carbonic acid (H₂CO₃), causing the pH of clean, unpolluted rain to range from about 5.2 to 5.6. What are the ranges of [H⁺] and [OH[−]] in the raindrops?

[H ⁺]	OH [−] (aq)	pH	pOH	Acidic or basic?
7.5 × 10 ^{−3} M	3.6 × 10 ^{−10} M	8.25		
			5.70	

STRONG ACIDS AND BASES (section 16.5)

- 16.41** (a) What is a strong acid? (b) A solution is labeled 0.500 M HCl. What is $[H^+]$ for the solution? (c) Which of the following are strong acids: HF, HCl, HBr, HI?
- 16.42** (a) What is a strong base? (b) A solution is labeled 0.035 M $Sr(OH)_2$. What is $[OH^-]$ for the solution? (c) Is the following statement true or false? Because $Mg(OH)_2$ is not very soluble, it cannot be a strong base. Explain.
- 16.43** Calculate the pH of each of the following strong acid solutions: (a) 8.5×10^{-3} M HBr, (b) 1.52 g of HNO_3 in 575 mL of solution, (c) 5.00 mL of 0.250 M $HClO_4$ diluted to 50.0 mL, (d) a solution formed by mixing 10.0 mL of 0.100 M HBr with 20.0 mL of 0.200 M HCl.
- 16.44** Calculate the pH of each of the following strong acid solutions: (a) 0.0167 M HNO_3 , (b) 0.225 g of $HClO_3$ in 2.00 L of solution, (c) 15.00 mL of 1.00 M HCl diluted to 0.500 L, (d) a mixture formed by adding 50.0 mL of 0.020 M HCl to 125 mL of 0.010 M HI.
- 16.45** Calculate $[OH^-]$ and pH for (a) 1.5×10^{-3} M $Sr(OH)_2$, (b) 2.250 g of LiOH in 250.0 mL of solution, (c) 1.00 mL of 0.175 M NaOH diluted to 2.00 L, (d) a solution formed by adding 5.00 mL of 0.105 M KOH to 15.0 mL of 9.5×10^{-2} M $Ca(OH)_2$.
- 16.46** Calculate $[OH^-]$ and pH for each of the following strong base solutions: (a) 0.182 M KOH, (b) 3.165 g of KOH in 500.0 mL of solution, (c) 10.0 mL of 0.0105 M $Ca(OH)_2$ diluted to 500.0 mL, (d) a solution formed by mixing 20.0 mL of 0.015 M $Ba(OH)_2$ with 40.0 mL of 8.2×10^{-3} M NaOH.
- 16.47** Calculate the concentration of an aqueous solution of NaOH that has a pH of 11.50.
- 16.48** Calculate the concentration of an aqueous solution of $Ca(OH)_2$ that has a pH of 10.05.

WEAK ACIDS (section 16.6)

- 16.49** Write the chemical equation and the K_a expression for the ionization of each of the following acids in aqueous solution. First show the reaction with $H^+(aq)$ as a product and then with the hydronium ion: (a) $HBrO_2$, (b) C_2H_5COOH .
- 16.50** Write the chemical equation and the K_a expression for the acid dissociation of each of the following acids in aqueous solution. First show the reaction with $H^+(aq)$ as a product and then with the hydronium ion: (a) C_6H_5COOH , (b) HCO_3^- .
- 16.51** Lactic acid ($CH_3CH(OH)COOH$) has one acidic hydrogen. A 0.10 M solution of lactic acid has a pH of 2.44. Calculate K_a .
- 16.52** Phenylacetic acid ($C_6H_5CH_2COOH$) is one of the substances that accumulates in the blood of people with phenylketonuria, an inherited disorder that can cause mental retardation or even death. A 0.085 M solution of $C_6H_5CH_2COOH$ has a pH of 2.68. Calculate the K_a value for this acid.
- 16.53** A 0.100 M solution of chloroacetic acid ($ClCH_2COOH$) is 11.0% ionized. Using this information, calculate $[ClCH_2COO^-]$, $[H^+]$, $[ClCH_2COOH]$, and K_a for chloroacetic acid.
- 16.54** A 0.100 M solution of bromoacetic acid ($BrCH_2COOH$) is 13.2% ionized. Calculate $[H^+]$, $[BrCH_2COO^-]$, $[BrCH_2COOH]$ and K_a for bromoacetic acid.
- 16.55** A particular sample of vinegar has a pH of 2.90. If acetic acid is the only acid that vinegar contains ($K_a = 1.8 \times 10^{-5}$), calculate the concentration of acetic acid in the vinegar.
- 16.56** If a solution of HF ($K_a = 6.8 \times 10^{-4}$) has a pH of 3.65, calculate the concentration of hydrofluoric acid.
- 16.57** The acid-dissociation constant for benzoic acid (C_6H_5COOH) is 6.3×10^{-5} . Calculate the equilibrium concentrations of H_3O^+ , $C_6H_5COO^-$, and C_6H_5COOH in the solution if the initial concentration of C_6H_5COOH is 0.050 M.
- 16.58** The acid-dissociation constant for chlorous acid ($HClO_2$) is 1.1×10^{-2} . Calculate the concentrations of H_3O^+ , ClO_2^- , and $HClO_2$ at equilibrium if the initial concentration of $HClO_2$ is 0.0125 M.
- 16.59** Calculate the pH of each of the following solutions (K_a and K_b values are given in Appendix D): (a) 0.095 M propionic acid (C_2H_5COOH), (b) 0.100 M hydrogen chromate ion ($HCrO_4^-$), (c) 0.120 M pyridine (C_5H_5N).
- 16.60** Determine the pH of each of the following solutions (K_a and K_b values are given in Appendix D): (a) 0.095 M hypochlorous acid, (b) 0.0085 M hydrazine, (c) 0.165 M hydroxylamine.
- 16.61** Saccharin, a sugar substitute, is a weak acid with $pK_a = 2.32$ at 25 °C. It ionizes in aqueous solution as follows:
- $$HNC_7H_4SO_3(aq) \rightleftharpoons H^+(aq) + NC_7H_4SO_3^-(aq)$$
- What is the pH of a 0.10 M solution of this substance?
- 16.62** The active ingredient in aspirin is acetylsalicylic acid ($HC_9H_7O_4$), a monoprotic acid with $K_a = 3.3 \times 10^{-4}$ at 25 °C. What is the pH of a solution obtained by dissolving two extra-strength aspirin tablets, containing 500 mg of acetylsalicylic acid each, in 250 mL of water?
- 16.63** Calculate the percent ionization of hydrazoic acid (HN_3) in solutions of each of the following concentrations (K_a is given in Appendix D): (a) 0.400 M, (b) 0.100 M, (c) 0.0400 M.
- 16.64** Calculate the percent ionization of propionic acid (C_2H_5COOH) in solutions of each of the following concentrations (K_a is given in Appendix D): (a) 0.250 M, (b) 0.0800 M, (c) 0.0200 M.
- 16.65** Show that for a weak acid, the percent ionization should vary as the inverse square root of the acid concentration.
- 16.66** For solutions of a weak acid, a graph of pH versus the logarithm of the initial acid concentration should be a straight line. What is the magnitude of the slope of that line?
- 16.67** Citric acid, which is present in citrus fruits, is a triprotic acid (Table 16.3). Calculate the pH of a 0.040 M solution of citric acid. Explain any approximations or assumptions you make in your calculations. Is the concentration of citrate ion ($C_6H_5O_7^{3-}$) equal to, less than, or greater than the H^+ ion concentration?
- 16.68** Tartaric acid is found in many fruits, including grapes, and is partially responsible for the dry texture of certain wines. Calculate the pH and the tartarate ion ($C_4H_4O_6^{2-}$) concentration for a 0.250 M solution of tartaric acid, for which the acid-dissociation constants are listed in Table 16.3. Explain any approximations or assumptions that you make in your calculation.

WEAK BASES (section 16.7)

- 16.69** Consider the base hydroxylamine, NH_2OH . (a) What is the conjugate acid of hydroxylamine? (b) When it acts as a base, which atom in hydroxylamine accepts a proton? (c) There are two atoms in hydroxylamine that have nonbonding electron pairs that could act as proton acceptors. Use Lewis structures and formal charges ∞ (Section 8.5) to rationalize why one of these two atoms is a much better proton acceptor than the other.
- 16.70** The hypochlorite ion, ClO^- , acts as a weak base. (a) Is ClO^- a stronger or weaker base than hydroxylamine? (b) When ClO^- acts as a base, which atom, Cl or O, acts as the proton acceptor? (c) Can you use formal charges to rationalize your answer to part (b)?
- 16.71** Write the chemical equation and the K_b expression for the reaction of each of the following bases with water: (a) dimethylamine, $(\text{CH}_3)_2\text{NH}$; (b) carbonate ion, CO_3^{2-} ; (c) formate ion, CHO_2^- .
- 16.72** Write the chemical equation and the K_b expression for the reaction of each of the following bases with water: (a) propylamine, $\text{C}_3\text{H}_7\text{NH}_2$; (b) monohydrogen phosphate ion, HPO_4^{2-} ; (c) benzoate ion, $\text{C}_6\text{H}_5\text{CO}_2^-$.
- 16.73** Calculate the molar concentration of OH^- ions in a 0.075 M solution of ethylamine ($\text{C}_2\text{H}_5\text{NH}_2$; $K_b = 6.4 \times 10^{-4}$). Calculate the pH of this solution.
- 16.74** Calculate the molar concentration of OH^- ions in a 0.724 M solution of hypobromite ion (BrO^- ; $K_b = 4.0 \times 10^{-6}$). What is the pH of this solution?
- 16.75** Ephedrine, a central nervous system stimulant, is used in nasal sprays as a decongestant. This compound is a weak organic base:
- $$\text{C}_{10}\text{H}_{15}\text{ON}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{C}_{10}\text{H}_{15}\text{ONH}^+(aq) + \text{OH}^-(aq)$$
- A 0.035 M solution of ephedrine has a pH of 11.33. (a) What are the equilibrium concentrations of $\text{C}_{10}\text{H}_{15}\text{ON}$, $\text{C}_{10}\text{H}_{15}\text{ONH}^+$, and OH^- ? (b) Calculate K_b for ephedrine.
- 16.76** Codeine ($\text{C}_{18}\text{H}_{21}\text{NO}_3$) is a weak organic base. A 5.0×10^{-3} M solution of codeine has a pH of 9.95. Calculate the value of K_b for this substance. What is the pK_b for this base?

THE K_a – K_b RELATIONSHIP; ACID–BASE PROPERTIES OF SALTS (sections 16.8 and 16.9)

- 16.77** Although the acid-dissociation constant for phenol ($\text{C}_6\text{H}_5\text{OH}$) is listed in Appendix D, the base-dissociation constant for the phenolate ion ($\text{C}_6\text{H}_5\text{O}^-$) is not. (a) Explain why it is not necessary to list both K_a for phenol and K_b for the phenolate ion. (b) Calculate K_b for the phenolate ion. (c) Is the phenolate ion a weaker or stronger base than ammonia?
- 16.78** Use the acid-dissociation constants in Table 16.3 to arrange these oxyanions from strongest base to weakest: SO_4^{2-} , CO_3^{2-} , SO_3^{2-} , and PO_4^{3-} .
- 16.79** (a) Given that K_a for acetic acid is 1.8×10^{-5} and that for hypochlorous acid is 3.0×10^{-8} , which is the stronger acid? (b) Which is the stronger base, the acetate ion or the hypochlorite ion? (c) Calculate K_b values for CH_3COO^- and ClO^- .
- 16.80** (a) Given that K_b for ammonia is 1.8×10^{-5} and that for hydroxylamine is 1.1×10^{-8} , which is the stronger base? (b) Which is the stronger acid, the ammonium ion or the hydroxylammonium ion? (c) Calculate K_a values for NH_4^+ and H_3NOH^+ .
- 16.81** Using data from Appendix D, calculate $[\text{OH}^-]$ and pH for each of the following solutions: (a) 0.10 M NaBrO, (b) 0.080 M NaHS, (c) a mixture that is 0.10 M in NaNO_2 and 0.20 M in $\text{Ca}(\text{NO}_2)_2$.
- 16.82** Using data from Appendix D, calculate $[\text{OH}^-]$ and pH for each of the following solutions: (a) 0.105 M NaF, (b) 0.035 M Na_2S , (c) a mixture that is 0.045 M in CH_3COONa and 0.055 M in $(\text{CH}_3\text{COO})_2\text{Ba}$.
- 16.83** Predict whether aqueous solutions of the following compounds are acidic, basic, or neutral: (a) NH_4Br , (b) FeCl_3 , (c) Na_2CO_3 , (d) KClO_4 , (e) NaHC_2O_4 .
- 16.84** Predict whether aqueous solutions of the following substances are acidic, basic, or neutral: (a) AlCl_3 , (b) NaBr , (c) NaClO , (d) $[\text{CH}_3\text{NH}_3]\text{NO}_3$, (e) Na_2SO_3 .
- 16.85** An unknown salt is either NaF, NaCl, or NaOCl. When 0.050 mol of the salt is dissolved in water to form 0.500 L of solution, the pH of the solution is 8.08. What is the identity of the salt?
- 16.86** An unknown salt is either KBr, NH_4Cl , KCN, or K_2CO_3 . If a 0.100 M solution of the salt is neutral, what is the identity of the salt?

ACID–BASE CHARACTER AND CHEMICAL STRUCTURE (section 16.10)

- 16.87** How does the acid strength of an oxyacid depend on (a) the electronegativity of the central atom; (b) the number of nonprotonated oxygen atoms in the molecule?
- 16.88** (a) Why is NH_3 a stronger base than H_2O ? (b) Why is NH_3 a stronger base than CH_4 ?
- 16.89** Explain the following observations: (a) HNO_3 is a stronger acid than HNO_2 ; (b) H_2S is a stronger acid than H_2O ; (c) H_2SO_4 is a stronger acid than HSO_4^- ; (d) H_2SO_4 is a stronger acid than H_2SeO_4 ; (e) CCl_3COOH is a stronger acid than CH_3COOH .
- 16.90** Explain the following observations: (a) HCl is a stronger acid than H_2S ; (b) H_3PO_4 is a stronger acid than H_3AsO_4 ; (c) HBrO_3 is a stronger acid than HBrO_2 ; (d) $\text{H}_2\text{C}_2\text{O}_4$ is a stronger acid than HC_2O_4^- ; (e) benzoic acid ($\text{C}_6\text{H}_5\text{COOH}$) is a stronger acid than phenol ($\text{C}_6\text{H}_5\text{OH}$).
- 16.91** Based on their compositions and structures and on conjugate acid–base relationships, select the stronger base in each of the following pairs: (a) BrO^- or ClO^- , (b) BrO^- or BrO_2^- , (c) HPO_4^{2-} or H_2PO_4^- .

16.92 Based on their compositions and structures and on conjugate acid–base relationships, select the stronger base in each of the following pairs: (a) NO_3^- or NO_2^- , (b) PO_4^{3-} or AsO_4^{3-} , (c) HCO_3^- or CO_3^{2-} .

16.93 Indicate whether each of the following statements is true or false. For each statement that is false, correct the statement to make it true. (a) In general, the acidity of binary acids increases from left to right in a given row of the periodic table. (b) In a series of acids that have the same central atom, acid strength increases with the number of hydrogen atoms bonded to the

central atom. (c) Hydrotelluric acid (H_2Te) is a stronger acid than H_2S because Te is more electronegative than S.

16.94 Indicate whether each of the following statements is true or false. For each statement that is false, correct the statement to make it true. (a) Acid strength in a series of $\text{H}-\text{X}$ molecules increases with increasing size of X. (b) For acids of the same general structure but differing electronegativities of the central atoms, acid strength decreases with increasing electronegativity of the central atom. (c) The strongest acid known is HF because fluorine is the most electronegative element.

LEWIS ACIDS AND BASES (section 16.11)

16.95 If a substance is an Arrhenius base, is it necessarily a Brønsted–Lowry base? Is it necessarily a Lewis base? Explain.

16.96 If a substance is a Lewis acid, is it necessarily a Brønsted–Lowry acid? Is it necessarily an Arrhenius acid? Explain.

16.97 Identify the Lewis acid and Lewis base among the reactants in each of the following reactions:

16.98 Identify the Lewis acid and Lewis base in each of the following reactions:

16.99 Predict which member of each pair produces the more acidic aqueous solution: (a) K^+ or Cu^{2+} , (b) Fe^{2+} or Fe^{3+} , (c) Al^{3+} or Ga^{3+} . Explain.

16.100 Which member of each pair produces the more acidic aqueous solution: (a) ZnBr_2 or CdCl_2 , (b) CuCl or $\text{Cu}(\text{NO}_3)_2$, (c) $\text{Ca}(\text{NO}_3)_2$ or NiBr_2 ? Explain.

ADDITIONAL EXERCISES

16.101 Triethylamine, $(\text{C}_2\text{H}_5)_3\text{N}$, has a $\text{p}K_b$ value of 2.99. Is triethylamine a stronger base than ammonia, NH_3 ?

16.102 Indicate whether each of the following statements is correct or incorrect. For those that are incorrect, explain why they are wrong.

(a) Every Brønsted–Lowry acid is also a Lewis acid.

(b) Every Lewis acid is also a Brønsted–Lowry acid.

(c) Conjugate acids of weak bases produce more acidic solutions than conjugate acids of strong bases.

(d) K^+ ion is acidic in water because it causes hydrating water molecules to become more acidic.

(e) The percent ionization of a weak acid in water increases as the concentration of acid decreases.

16.103 Use Figure 16.3 to predict whether the equilibrium lies to the right or to the left in the following reactions:

16.104 The odor of fish is due primarily to amines, especially methylamine (CH_3NH_2). Fish is often served with a wedge of lemon, which contains citric acid. The amine and the acid react forming a product with no odor, thereby making the less-than-fresh fish more appetizing. Using data from Appendix D, calculate the equilibrium constant for the reaction of citric acid with methylamine, if only the first proton of the citric acid (K_{a1}) is important in the neutralization reaction.

16.105 Hemoglobin plays a part in a series of equilibria involving protonation-deprotonation and oxygenation-deoxygenation. The overall reaction is approximately as follows:

where Hb stands for hemoglobin and HbO_2 for oxyhemoglobin. (a) The concentration of O_2 is higher in the lungs and lower in the tissues. What effect does high $[\text{O}_2]$ have on the position of this equilibrium? (b) The normal pH of blood is 7.4. Is the blood acidic, basic, or neutral? (c) If the blood pH is lowered by the presence of large amounts of acidic metabolism products, a condition known as acidosis results. What effect does lowering blood pH have on the ability of hemoglobin to transport O_2 ?

[16.106] Calculate the pH of a solution made by adding 2.50 g of lithium oxide (Li_2O) to enough water to make 1.500 L of solution.

16.107 Which of the following solutions has the higher pH? (a) a 0.1 M solution of a strong acid or a 0.1 M solution of a weak acid, (b) a 0.1 M solution of an acid with $K_a = 2 \times 10^{-3}$ or one with $K_a = 8 \times 10^{-6}$, (c) a 0.1 M solution of a base with $\text{p}K_b = 4.5$ or one with $\text{p}K_b = 6.5$.

16.108 What is the pH of a solution that is 2.5×10^{-9} in NaOH ? Does your answer make sense? What assumption do we normally make that is not valid in this case?

16.109 Caproic acid ($\text{C}_5\text{H}_{11}\text{COOH}$) is found in small amounts in coconut and palm oils and is used in making artificial flavors. A saturated solution of the acid contains 11 g/L and has a pH of 2.94. Calculate K_a for the acid.

16.110 Butyric acid is responsible for the foul smell of rancid butter. The pK_a of butyric acid is 4.84. (a) Calculate the pK_b for the butyrate ion. (b) Calculate the pH of a 0.050 *M* solution of butyric acid. (c) Calculate the pH of a 0.050 *M* solution of sodium butyrate.

16.111 Arrange the following 0.10 *M* solutions in order of increasing acidity (decreasing pH): (i) NH_4NO_3 , (ii) NaNO_3 , (iii) $\text{CH}_3\text{COONH}_4$, (iv) NaF , (v) CH_3COONa .

[16.112] Many moderately large organic molecules containing basic nitrogen atoms are not very soluble in water as neutral molecules, but they are frequently much more soluble as their acid salts. Assuming that pH in the stomach is 2.5, indicate whether each of the following compounds would be present in the stomach as the neutral base or in the protonated form: nicotine, $K_b = 7 \times 10^{-7}$; caffeine, $K_b = 4 \times 10^{-14}$; strychnine, $K_b = 1 \times 10^{-6}$; quinine, $K_b = 1.1 \times 10^{-6}$.

[16.113] The amino acid glycine ($\text{H}_2\text{N}-\text{CH}_2-\text{COOH}$) can participate in the following equilibria in water:

(a) Use the values of K_a and K_b to estimate the equilibrium constant for the intramolecular proton transfer to form a zwitterion:

What assumptions did you need to make? (b) What is the pH of a 0.050 *M* aqueous solution of glycine? (c) What would be the predominant form of glycine in a solution with pH 13? With pH 1?

16.114 The structural formula for acetic acid is shown in Table 16.2. Replacing hydrogen atoms on the carbon with chlorine atoms causes an increase in acidity, as follows:

Acid	Formula	$K_a(25^\circ\text{C})$
Acetic	CH_3COOH	1.8×10^{-5}
Chloroacetic	CH_2ClCOOH	1.4×10^{-3}
Dichloroacetic	CHCl_2COOH	3.3×10^{-2}
Trichloroacetic	CCl_3COOH	2×10^{-1}

Using Lewis structures as the basis of your discussion, explain the observed trend in acidities in the series. Calculate the pH of a 0.010 *M* solution of each acid.

INTEGRATIVE EXERCISES

- 16.115** Calculate the number of H^+ (aq) ions in 1.0 mL of pure water at 25 °C.
- 16.116** How many milliliters of concentrated hydrochloric acid solution (36.0% HCl by mass, density = 1.18 g/mL) are required to produce 10.0 L of a solution that has a pH of 2.05?
- 16.117** The volume of an adult's stomach ranges from about 50 mL when empty to 1 L when full. If the stomach volume is 400 mL and its contents have a pH of 2, how many moles of H^+ does the stomach contain? Assuming that all the H^+ comes from HCl, how many grams of sodium hydrogen carbonate will totally neutralize the stomach acid?
- 16.118** Atmospheric CO_2 levels have risen by nearly 20% over the past 40 years from 315 ppm to 380 ppm. (a) Given that the average pH of clean, unpolluted rain today is 5.4, determine the pH of unpolluted rain 40 years ago. Assume that carbonic acid (H_2CO_3) formed by the reaction of CO_2 and water is the only factor influencing pH.
- $$\text{CO}_2(g) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_2\text{CO}_3(aq)$$
- (b) What volume of CO_2 at 25 °C and 1.0 atm is dissolved in a 20.0-L bucket of today's rainwater?
- 16.119** In many reactions the addition of AlCl_3 produces the same effect as the addition of H^+ . (a) Draw a Lewis structure for AlCl_3 in which no atoms carry formal charges, and determine its structure using the VSEPR method. (b) What characteristic is notable about the structure in part (a) that helps us understand the acidic character of AlCl_3 ? (c) Predict the result of the reaction between AlCl_3 and NH_3 in a solvent that does not participate as a reactant. (d) Which acid–base theory is most suitable for discussing the similarities between AlCl_3 and H^+ ?
- 16.120** What is the boiling point of a 0.10 M solution of NaHSO_4 if the solution has a density of 1.002 g/mL?
- 16.121** Use average bond enthalpies from Table 8.4 to estimate the enthalpies of the following gas-phase reactions:
- Reaction 1: $\text{HF}(g) + \text{H}_2\text{O}(g) \rightleftharpoons \text{F}^-(g) + \text{H}_3\text{O}^+(g)$
 Reaction 2: $\text{HCl}(g) + \text{H}_2\text{O}(g) \rightleftharpoons \text{Cl}^-(g) + \text{H}_3\text{O}^+(g)$
- Are both reactions exothermic? How do these values relate to the different strengths of hydrofluoric and hydrochloric acid?
- [16.122]** Cocaine is a weak organic base whose molecular formula is $\text{C}_{17}\text{H}_{21}\text{NO}_4$. An aqueous solution of cocaine was found to have a pH of 8.53 and an osmotic pressure of 52.7 torr at 15 °C. Calculate K_b for cocaine.
- [16.123]** The iodate ion is reduced by sulfite according to the following reaction:
- $$\text{IO}_3^-(aq) + 3\text{SO}_3^{2-}(aq) \longrightarrow \text{I}^-(aq) + 3\text{SO}_4^{2-}(aq)$$
- The rate of this reaction is found to be first order in IO_3^- , first order in SO_3^{2-} , and first order in H^+ . (a) Write the rate law for the reaction. (b) By what factor will the rate of the reaction change if the pH is lowered from 5.00 to 3.50? Does the reaction proceed more quickly or more slowly at the lower pH? (c) By using the concepts discussed in Section 14.6, explain how the reaction can be pH-dependent even though H^+ does not appear in the overall reaction.
- 16.124** (a) Using dissociation constants from Appendix D, determine the value for the equilibrium constant for each of the following reactions.
- (i) $\text{HCO}_3^-(aq) + \text{OH}^-(aq) \rightleftharpoons \text{CO}_3^{2-}(aq) + \text{H}_2\text{O}(l)$
 (ii) $\text{NH}_4^+(aq) + \text{CO}_3^{2-}(aq) \rightleftharpoons \text{NH}_3(aq) + \text{HCO}_3^-(aq)$
- (b) We usually use single arrows for reactions when the forward reaction is appreciable (K much greater than 1) or when products escape from the system, so that equilibrium is never established. If we follow this convention, which of these equilibria might be written with a single arrow?

WHAT'S AHEAD

17.1 THE COMMON-ION EFFECT

We begin by considering a specific example of Le Châtelier's principle known as the common-ion effect.

17.2 BUFFERED SOLUTIONS

We consider the composition of buffered solutions and learn how they resist pH change when small amounts of a strong acid or strong base are added to them.

17.3 ACID-BASE TITRATIONS

We examine acid-base titrations and explore how to determine pH at any point in an acid-base titration.

17.4 SOLUBILITY EQUILIBRIA

We learn how to use *solubility-product constants* to determine to what extent a sparingly soluble salt dissolves in water.

THE GREAT BARRIER REEF stretches for more than 2600 km off of the eastern coast of Australia. Coral reefs such as this are among the most diverse ecosystems on the planet.

17.5 FACTORS THAT AFFECT SOLUBILITY

We investigate some of the factors that affect solubility, including the common-ion effect and the effect of acids.

17.6 PRECIPITATION AND SEPARATION OF IONS

We learn how differences in solubility can be used to separate ions through selective precipitation.

17.7 QUALITATIVE ANALYSIS FOR METALLIC ELEMENTS

We explain how the principles of solubility and complexation equilibria can be used to identify ions in solution.

ADDITIONAL ASPECTS OF AQUEOUS EQUILIBRIA

WATER, THE MOST COMMON AND most important solvent on Earth, occupies its position of importance because of its abundance and its exceptional ability to dissolve a wide variety of substances. Coral reefs are a striking example of aqueous chemistry at work in nature. Coral reefs are built by tiny animals

called stony corals, which secrete a hard calcium carbonate exoskeleton. Over time, the stony corals build up large networks of calcium carbonate upon which a reef is built. The size of such structures can be immense, as illustrated by the Great Barrier Reef.

Stony corals make their exoskeletons from dissolved Ca^{2+} and CO_3^{2-} ions. This process is aided by the fact that the CO_3^{2-} concentration is supersaturated in most parts of the ocean. However, well-documented increases in the amount of CO_2 in the atmosphere threaten to upset the aqueous chemistry that stony corals depend on. As atmospheric CO_2 levels increase, the amount of CO_2 dissolved in the ocean also

increases. This lowers the pH of the ocean and leads to a decrease in the CO_3^{2-} concentration. As a result it becomes more difficult for stony corals and other important ocean creatures to maintain their exoskeletons. We will take a closer look at the consequences of ocean acidification later in the chapter.

To understand the chemistry that underlies coral reef formation, we must understand the concepts of aqueous equilibria. In this chapter we take a step toward understanding such complex solutions by looking first at further applications of acid–base equilibria. The idea is to consider not only solutions in which there is a single solute but also those containing a mixture of solutes. We then broaden our discussion to include two additional types of aqueous equilibria: those involving slightly soluble salts and those involving the formation of metal complexes in solution. For the most part, the discussions and calculations in this chapter are an extension of those in Chapters 15 and 16.

17.1 THE COMMON-ION EFFECT

In Chapter 16 we examined the equilibrium concentrations of ions in solutions containing a weak acid or a weak base. We now consider solutions that contain a weak acid, such as acetic acid (CH_3COOH), and a soluble salt of that acid, such as sodium acetate (CH_3COONa). Notice that these solutions contain two substances that share a *common ion*, CH_3COO^- . It is instructive to view these solutions from the perspective of Le Châtelier's principle. [∞ \(Section 15.7\)](#)

Sodium acetate is a soluble ionic compound and therefore a strong electrolyte. [∞ \(Section 4.1\)](#) Consequently, it dissociates completely in aqueous solution to form Na^+ and CH_3COO^- ions:

In contrast, CH_3COOH is a weak electrolyte that ionizes only partially, represented by the equilibrium

When we have sodium acetate and acetic acid in the same solution, the CH_3COO^- from CH_3COONa causes the equilibrium of Equation 17.1 to shift to the left, thereby decreasing the equilibrium concentration of $\text{H}^+(aq)$:

In other words, the presence of the added acetate ion causes the acetic acid to ionize less than it normally would.

*Whenever a weak electrolyte and a strong electrolyte containing a common ion are together in solution, the weak electrolyte ionizes less than it would if it were alone in solution. We call this observation the **common-ion effect**.*

SAMPLE EXERCISE 17.1 Calculating the pH When a Common Ion Is Involved

What is the pH of a solution made by adding 0.30 mol of acetic acid and 0.30 mol of sodium acetate to enough water to make 1.0 L of solution?

SOLUTION

Analyze We are asked to determine the pH of a solution of a weak electrolyte (CH_3COOH) and a strong electrolyte (CH_3COONa) that share a common ion, CH_3COO^- .

Plan In any problem in which we must determine the pH of a solution containing a mixture of solutes, it is helpful to proceed by a series of logical steps:

1. Consider which solutes are strong electrolytes and which are weak electrolytes, and identify the major species in solution.
2. Identify the important equilibrium that is the source of H^+ and therefore determines pH.
3. Tabulate the concentrations of ions involved in the equilibrium.
4. Use the equilibrium-constant expression to calculate $[\text{H}^+]$ and then pH.

Solve First, because CH_3COOH is a weak electrolyte and CH_3COONa is a strong electrolyte, the major species in the solution are CH_3COOH (a weak acid), Na^+ (which is neither acidic nor basic and is therefore a spectator in the acid–base chemistry), and CH_3COO^- (which is the conjugate base of CH_3COOH).

Second, $[\text{H}^+]$ and, therefore, the pH are controlled by the dissociation equilibrium of CH_3COOH :

[We have written the equilibrium using $\text{H}^+(aq)$ rather than $\text{H}_3\text{O}^+(aq)$, but both representations of the hydrated hydrogen ion are equally valid.]

Third, we tabulate the initial and equilibrium concentrations as we did in solving other equilibrium problems in Chapters 15 and 16:

Initial	0.30 M	0	0.30 M
Change	$-x$ M	$+x$ M	$+x$ M
Equilibrium	$(0.30 - x)$ M	x M	$(0.30 + x)$ M

The equilibrium concentration of CH_3COO^- (the common ion) is the initial concentration that is due to CH_3COONa (0.30 M) plus the change in concentration (x) that is due to the ionization of CH_3COOH .

Now we can use the equilibrium-constant expression:

$$K_a = 1.8 \times 10^{-5} = \frac{[\text{H}^+][\text{CH}_3\text{COO}^-]}{[\text{CH}_3\text{COOH}]}$$

The dissociation constant for CH_3COOH at 25 °C is from Appendix D; addition of CH_3COONa does not change the value of this constant. Substituting the equilibrium-constant concentrations from our table into the equilibrium expression gives:

$$K_a = 1.8 \times 10^{-5} = \frac{x(0.30 + x)}{0.30 - x}$$

Because K_a is small, we assume that x is small compared to the original concentrations of CH_3COOH and CH_3COO^- (0.30 M each). Thus, we can ignore the very small x relative to 0.30 M, giving:

$$K_a = 1.8 \times 10^{-5} = \frac{x(0.30)}{0.30}$$

The resulting value of x is indeed small relative to 0.30, justifying the approximation made in simplifying the problem.

$$x = 1.8 \times 10^{-5} \text{ M} = [\text{H}^+]$$

Finally, we calculate the pH from the equilibrium concentration of $\text{H}^+(aq)$:

$$\text{pH} = -\log(1.8 \times 10^{-5}) = 4.74$$

Comment In Section 16.6 we calculated that a 0.30 M solution of CH_3COOH has a pH of 2.64, corresponding to $[\text{H}^+] = 2.3 \times 10^{-3}$ M. Thus, the addition of CH_3COONa has substantially decreased $[\text{H}^+]$, as we expect from Le Châtelier's principle.

PRACTICE EXERCISE

Calculate the pH of a solution containing 0.085 M nitrous acid (HNO_2 , $K_a = 4.5 \times 10^{-4}$) and 0.10 M potassium nitrite (KNO_2).

Answer: 3.42

SAMPLE EXERCISE 17.2 Calculating Ion Concentrations When a Common Ion Is Involved

Calculate the fluoride ion concentration and pH of a solution that is 0.20 M in HF and 0.10 M in HCl.

SOLUTION

Analyze We are asked to determine the concentration of F^- and the pH in a solution containing the weak acid HF and the strong acid HCl. In this case the common ion is H^+ .

Plan We can again use the four steps outlined in Sample Exercise 17.1.

Solve Because HF is a weak acid and HCl is a strong acid, the major species in solution are HF, H^+ , and Cl^- . The Cl^- , which is the conjugate base of a strong acid, is merely a spectator ion in any acid–base chemistry. The problem asks for $[F^-]$, which is formed by ionization of HF. Thus, the important equilibrium is

The common ion in this problem is the hydrogen (or hydronium) ion. Now we can tabulate the initial and equilibrium concentrations of each species involved in this equilibrium:

	HF(aq)	$H^+(aq)$	+ $F^-(aq)$
Initial	0.20 M	0.10 M	0
Change	-x M	+x M	+x M
Equilibrium	(0.20 - x) M	(0.10 + x) M	x M

The equilibrium constant for the ionization of HF, from Appendix D, is 6.8×10^{-4} . Substituting the equilibrium-constant concentrations into the equilibrium expression gives

$$K_a = 6.8 \times 10^{-4} = \frac{[H^+][F^-]}{[HF]} = \frac{(0.10 + x)(x)}{0.20 - x}$$

If we assume that x is small relative to 0.10 or 0.20 M, this expression simplifies to

$$\begin{aligned} \frac{(0.10)(x)}{0.20} &= 6.8 \times 10^{-4} \\ x &= \frac{0.20}{0.10}(6.8 \times 10^{-4}) = 1.4 \times 10^{-3} M = [F^-] \end{aligned}$$

This F^- concentration is substantially smaller than it would be in a 0.20 M solution of HF with no added HCl. The common ion, H^+ , suppresses the ionization of HF. The concentration of $H^+(aq)$ is

$$[H^+] = (0.10 + x) M \approx 0.10 M$$

Thus,

$$\text{pH} = 1.00$$

Comment Notice that for all practical purposes, the hydrogen ion concentration is due entirely to the HCl; the HF makes a negligible contribution by comparison.

PRACTICE EXERCISE

Calculate the formate ion concentration and pH of a solution that is 0.050 M in formic acid ($HCOOH$, $K_a = 1.8 \times 10^{-4}$) and 0.10 M in HNO_3 .

Answer: $[HCOO^-] = 9.0 \times 10^{-5}$, pH = 1.00

Sample Exercises 17.1 and 17.2 both involve weak acids. The ionization of a weak base is also decreased by the addition of a common ion. For example, the addition of NH_4^+ (as from the strong electrolyte NH_4Cl) causes the base-dissociation equilibrium of NH_3 to shift to the left, decreasing the equilibrium concentration of OH^- and lowering the pH:

Addition of NH_4^+ shifts equilibrium, reducing $[OH^-]$

GIVE IT SOME THOUGHT

If solutions of $\text{NH}_4\text{Cl}(aq)$ and $\text{NH}_3(aq)$ are mixed, which ions in the resulting solution are spectator ions in any acid–base chemistry occurring in the solution? What equilibrium reaction determines $[\text{OH}^-]$ and, therefore, the pH of the solution?

17.2 | BUFFERED SOLUTIONS

Solutions that contain a weak conjugate acid–base pair, such as those discussed in Section 17.1, resist drastic changes in pH when small amounts of strong acid or strong base are added to them. These solutions are called **buffered solutions** (or merely **buffers**). Human blood, for example, is a complex buffered solution that maintains the blood pH at about 7.4 (see the “Chemistry and Life” box on page 713). Much of the chemical behavior of seawater is determined by its pH, buffered at about 8.1 to 8.3 near the surface (see “Chemistry and Life” box on page 728). Buffered solutions find many important applications in the laboratory and in medicine (► **FIGURE 17.1**).

Composition and Action of Buffered Solutions

A buffer resists changes in pH because it contains both an acid to neutralize added OH^- ions and a base to neutralize added H^+ ions. The acid and base that make up the buffer, however, must not consume each other through a neutralization reaction. These requirements are fulfilled by a weak acid–base conjugate pair, such as $\text{CH}_3\text{COOH}-\text{CH}_3\text{COO}^-$ or $\text{NH}_4^+-\text{NH}_3$. Thus, buffers are often prepared by mixing a weak acid or a weak base with a salt of that acid or base. The $\text{CH}_3\text{COOH}-\text{CH}_3\text{COO}^-$ buffer can be prepared, for example, by adding CH_3COONa to a solution of CH_3COOH . The $\text{NH}_4^+-\text{NH}_3$ buffer can be prepared by adding NH_4Cl to a solution of NH_3 . By choosing appropriate components and adjusting their relative concentrations, we can buffer a solution at virtually any pH.

GIVE IT SOME THOUGHT

Which of these conjugate acid–base pairs will *not* function as a buffer: $\text{C}_2\text{H}_5\text{COOH}$ and $\text{C}_2\text{H}_5\text{COO}^-$, HCO_3^- and CO_3^{2-} , or HNO_3 and NO_3^- ? Explain.

To understand how a buffer works, let’s consider one composed of a weak acid HX and one of its salts MX , where M^+ could be Na^+ , K^+ , or any other cation that does not react with water. The acid–dissociation equilibrium in this buffered solution involves both the acid and its conjugate base:

The corresponding acid–dissociation–constant expression is

$$K_a = \frac{[\text{H}^+][\text{X}^-]}{[\text{HX}]} \quad [17.4]$$

Solving this expression for $[\text{H}^+]$, we have

$$[\text{H}^+] = K_a \frac{[\text{HX}]}{[\text{X}^-]} \quad [17.5]$$

We see from this expression that $[\text{H}^+]$ and, thus, the pH are determined by two factors: the value of K_a for the weak-acid component of the buffer and the ratio of the concentrations of the conjugate acid–base pair, $[\text{HX}]/[\text{X}^-]$.

If OH^- ions are added to the buffered solution, they react with the buffer acid component to produce water and X^- :

▲ **FIGURE 17.1** Buffered solutions. For laboratory work, prepackaged buffered solutions can be purchased.

▲ FIGURE 17.2 Buffer action. The pH of an HF/F⁻ buffered solution changes by only a small amount in response to addition of an acid or base.

This reaction causes [HX] to decrease and [X⁻] to increase. As long as the amounts of HX and X⁻ in the buffer are large relative to the amount of OH⁻ added, the ratio [HX]/[X⁻] does not change much and, thus, the change in pH is small.

If H⁺ ions are added, they react with the base component of the buffer:

This reaction can also be represented using H₃O⁺:

Using either equation, we see that the reaction causes [X⁻] to decrease and [HX] to increase. As long as the change in the ratio [HX]/[X⁻] is small, the change in pH will be small.

▲ FIGURE 17.2 shows an HX/MX buffer consisting of equal concentrations of hydrofluoric acid and fluoride ion (center). The addition of OH⁻ reduces [HF] and increases [F⁻], whereas the addition of [H⁺] reduces [F⁻] and increases [HF].

▲ GIVE IT SOME THOUGHT

- What happens when NaOH is added to a buffer composed of CH₃COOH and CH₃COO⁻?
- What happens when HCl is added to this buffer?

Calculating the pH of a Buffer

Because conjugate acid–base pairs share a common ion, we can use the same procedures to calculate the pH of a buffer that we used to treat the common-ion effect in Sample Exercise 17.1. Alternatively, we can take an approach based on an equation derived from Equation 17.5. Taking the negative logarithm of both sides of Equation 17.5, we have

$$-\log[\text{H}^+] = -\log\left(K_a \frac{[\text{HX}]}{[\text{X}^-]}\right) = -\log K_a - \log \frac{[\text{HX}]}{[\text{X}^-]}$$

Because $-\log[\text{H}^+] = \text{pH}$ and $-\log K_a = \text{p}K_a$, we have

$$\text{pH} = \text{p}K_a - \log \frac{[\text{HX}]}{[\text{X}^-]} = \text{p}K_a + \log \frac{[\text{X}^-]}{[\text{HX}]} \quad [17.8]$$

In general,

$$\text{pH} = \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} \quad [17.9]$$

where [acid] and [base] refer to the equilibrium concentrations of the *conjugate acid–base pair*. Note that when [base] = [acid], we have $\text{pH} = \text{p}K_a$.

Equation 17.9 is known as the **Henderson–Hasselbalch equation**. Biologists, biochemists, and others who work frequently with buffers often use this equation to calculate the pH of buffers. In doing equilibrium calculations, we have seen that we can normally neglect the amounts of the acid and base of the buffer that ionize. Therefore, we can usually use the starting concentrations of the acid and base components of the buffer directly in Equation 17.9.

SAMPLE EXERCISE 17.3 Calculating the pH of a Buffer

What is the pH of a buffer that is 0.12 M in lactic acid [$\text{CH}_3\text{CH}(\text{OH})\text{COOH}$, or $\text{HC}_3\text{H}_5\text{O}_3$] and 0.10 M in sodium lactate [$\text{CH}_3\text{CH}(\text{OH})\text{COONa}$, or $\text{NaC}_3\text{H}_5\text{O}_3$]? For lactic acid, $K_a = 1.4 \times 10^{-4}$.

SOLUTION

Analyze We are asked to calculate the pH of a buffer containing lactic acid ($\text{HC}_3\text{H}_5\text{O}_3$) and its conjugate base, the lactate ion ($\text{C}_3\text{H}_5\text{O}_3^-$).

Plan We will first determine the pH using the method described in Section 17.1. Because $\text{HC}_3\text{H}_5\text{O}_3$ is a weak electrolyte and $\text{NaC}_3\text{H}_5\text{O}_3$ is a strong electrolyte, the major species in solution are $\text{HC}_3\text{H}_5\text{O}_3$, Na^+ , and $\text{C}_3\text{H}_5\text{O}_3^-$. The Na^+ ion is a spectator ion. The $\text{HC}_3\text{H}_5\text{O}_3$ – $\text{C}_3\text{H}_5\text{O}_3^-$ conjugate acid–base pair determines $[\text{H}^+]$ and, thus, pH; $[\text{H}^+]$ can be determined using the acid-dissociation equilibrium of lactic acid.

Solve The initial and equilibrium concentrations of the species involved in this equilibrium are

	$\text{HC}_3\text{H}_5\text{O}_3(aq)$	\rightleftharpoons	$\text{H}^+(aq)$	+	$\text{C}_3\text{H}_5\text{O}_3^-(aq)$
Initial	0.12 M		0		0.10 M
Change	$-x$ M		$+x$ M		$+x$ M
Equilibrium	$(0.12 - x)$ M		x M		$(0.10 + x)$ M

The equilibrium concentrations are governed by the equilibrium expression:

$$K_a = 1.4 \times 10^{-4} = \frac{[\text{H}^+][\text{C}_3\text{H}_5\text{O}_3^-]}{[\text{HC}_3\text{H}_5\text{O}_3]} = \frac{x(0.10 + x)}{(0.12 - x)}$$

Because K_a is small and a common ion is present, we expect x to be small relative to either 0.12 or 0.10 M. Thus, our equation can be simplified to give

$$K_a = 1.4 \times 10^{-4} = \frac{x(0.10)}{0.12}$$

Solving for x gives a value that justifies our approximation:

$$[\text{H}^+] = x = \left(\frac{0.12}{0.10}\right)(1.4 \times 10^{-4}) = 1.7 \times 10^{-4} \text{ M}$$

$$\text{pH} = -\log(1.7 \times 10^{-4}) = 3.77$$

Alternatively, we can use the Henderson–Hasselbalch equation to calculate pH directly:

$$\begin{aligned} \text{pH} &= \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} = 3.85 + \log \left(\frac{0.10}{0.12}\right) \\ &= 3.85 + (-0.08) = 3.77 \end{aligned}$$

PRACTICE EXERCISE

Calculate the pH of a buffer composed of 0.12 M benzoic acid and 0.20 M sodium benzoate. (Refer to Appendix D.)

Answer: 4.42

In Sample Exercise 17.3 we calculated the pH of a buffered solution. Often we will need to work in the opposite direction by calculating the amounts of the acid and its conjugate base needed to achieve a specific pH. This calculation is illustrated in Sample Exercise 17.4.

SAMPLE EXERCISE 17.4 Preparing a Buffer

How many moles of NH_4Cl must be added to 2.0 L of 0.10 M NH_3 to form a buffer whose pH is 9.00? (Assume that the addition of NH_4Cl does not change the volume of the solution.)

SOLUTION

Analyze We are asked to determine the amount of NH_4^+ ion required to prepare a buffer of a specific pH.

Plan The major species in the solution will be NH_4^+ , Cl^- , and NH_3 . Of these, the Cl^- ion is a spectator (it is the conjugate base of a strong acid). Thus, the NH_4^+ – NH_3 conjugate acid–base pair will determine the pH of the buffer. The equilibrium relationship between NH_4^+ and NH_3 is given by the base-dissociation reaction for NH_3 :

The key to this exercise is to use this K_b expression to calculate $[\text{NH}_4^+]$.

Solve We obtain $[\text{OH}^-]$ from the given pH:

$$\text{pOH} = 14.00 - \text{pH} = 14.00 - 9.00 = 5.00$$

and so

$$[\text{OH}^-] = 1.0 \times 10^{-5} M$$

Because K_b is small and the common ion $[\text{NH}_4^+]$ is present, the equilibrium concentration of NH_3 essentially equals its initial concentration:

$$[\text{NH}_3] = 0.10 M$$

We now use the expression for K_b to calculate $[\text{NH}_4^+]$:

$$[\text{NH}_4^+] = K_b \frac{[\text{NH}_3]}{[\text{OH}^-]} = (1.8 \times 10^{-5}) \frac{(0.10 M)}{(1.0 \times 10^{-5} M)} = 0.18 M$$

Thus, for the solution to have pH = 9.00, $[\text{NH}_4^+]$ must equal 0.18 M. The number of moles of NH_4Cl needed to produce this concentration is given by the product of the volume of the solution and its molarity:

$$(2.0 \text{ L})(0.18 \text{ mol NH}_4\text{Cl/L}) = 0.36 \text{ mol NH}_4\text{Cl}$$

Comment Because NH_4^+ and NH_3 are a conjugate acid–base pair, we could use the Henderson–Hasselbalch equation (Equation 17.9) to solve this problem. To do so requires first using Equation 16.41 to calculate $\text{p}K_a$ for NH_4^+ from the value of $\text{p}K_a$ for NH_3 . We suggest

you try this approach to convince yourself that you can use the Henderson–Hasselbalch equation for buffers for which you are given K_b for the conjugate base rather than K_a for the conjugate acid.

PRACTICE EXERCISE

Calculate the concentration of sodium benzoate that must be present in a 0.20 M solution of benzoic acid ($\text{C}_6\text{H}_5\text{COOH}$) to produce a pH of 4.00.

Answer: 0.13 M

Buffer Capacity and pH Range

Two important characteristics of a buffer are its capacity and its effective pH range. **Buffer capacity** is the amount of acid or base the buffer can neutralize before the pH begins to change to an appreciable degree. The buffer capacity depends on the amount of acid and base used to prepare the buffer. According to Equation 17.5, for example, the pH of a 1-L solution that is 1 M in CH_3COOH and 1 M in CH_3COONa is the same as the pH of a 1-L solution that is 0.1 M in CH_3COOH and 0.1 M in CH_3COONa . The first

solution has a greater buffering capacity, however, because it contains more CH_3COOH and CH_3COO^- .

The **pH range** of any buffer is the pH range over which the buffer acts effectively. Buffers most effectively resist a change in pH in *either* direction when the concentrations of weak acid and conjugate base are about the same. From Equation 17.9 we see that when the concentrations of weak acid and conjugate base are equal, $\text{pH} = \text{p}K_a$. This relationship gives the optimal pH of any buffer. Thus, we usually try to select a buffer whose acid form has a $\text{p}K_a$ close to the desired pH. In practice, we find that if the concentration of one component of the buffer is more than 10 times the concentration of the other component, the buffering action is poor. Because $\log 10 = 1$, *buffers usually have a usable range within ± 1 pH unit of $\text{p}K_a$* (that is, a range of $\text{pH} = \text{p}K_a \pm 1$).

GIVE IT SOME THOUGHT

The K_a values for nitrous acid (HNO_2) and hypochlorous (HClO) acid are 4.5×10^{-4} and 3.0×10^{-8} , respectively. Which one would be more suitable for use in a solution buffered at $\text{pH} = 7.0$? What other substance would be needed to make the buffer?

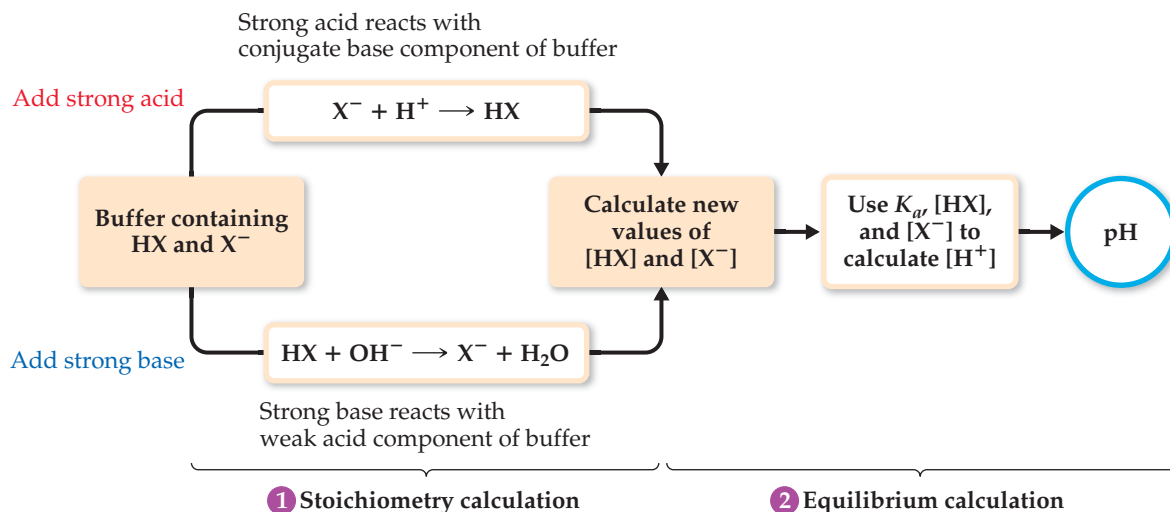

Addition of Strong Acids or Bases to Buffers

Let's now consider in a more quantitative way how a buffered solution responds to addition of a strong acid or base. In this discussion, it is important to understand that *reactions between strong acids and weak bases proceed essentially to completion, as do those between strong bases and weak acids*. Thus, as long as we do not exceed the buffering capacity of the buffer, we can assume that the strong acid or strong base is completely consumed by reaction with the buffer.

Consider a buffer that contains a weak acid HX and its conjugate base X^- . When a strong acid is added to this buffer, the added H^+ is consumed by X^- to produce HX ; thus, $[\text{HX}]$ increases and $[\text{X}^-]$ decreases. (See Equation 17.7.) Upon addition of a strong base, the added OH^- is consumed by HX to produce X^- ; in this case $[\text{HX}]$ decreases and $[\text{X}^-]$ increases. (See Equation 17.6.) These two situations are summarized in Figure 17.2.

To calculate how the pH of the buffer responds to the addition of a strong acid or a strong base, we follow the strategy outlined in  **FIGURE 17.3**:

1. Consider the acid–base neutralization reaction and determine its effect on $[\text{HX}]$ and $[\text{X}^-]$. This step is a *stoichiometry calculation*.  (Section 3.6)
2. Use the calculated values of $[\text{HX}]$ and $[\text{X}^-]$ along with K_a to calculate $[\text{H}^+]$. This step is an *equilibrium calculation* and is most easily done using the Henderson–Hasselbalch equation.

 **FIGURE 17.3** Calculating the pH of a buffer after addition of an acid or base.

SAMPLE EXERCISE 17.5 Calculating pH Changes in Buffers

A buffer is made by adding 0.300 mol CH_3COOH and 0.300 mol CH_3COONa to enough water to make 1.000 L of solution. The pH of the buffer is 4.74 (Sample Exercise 17.1). (a) Calculate the pH of this solution after 5.0 mL of 4.0 M $\text{NaOH}(aq)$ solution is added. (b) For comparison, calculate the pH of a solution made by adding 5.0 mL of 4.0 M $\text{NaOH}(aq)$ solution to 1.000 L of pure water.

SOLUTION

Analyze We are asked to determine the pH of a buffer after addition of a small amount of strong base and to compare the pH change with the pH that would result if we were to add the same amount of strong base to pure water.

Plan Solving this problem involves the two steps outlined in Figure 17.3. First we do a stoichiometry calculation to determine how the added OH^- affects the buffer composition. Then we use the resultant buffer composition and either the Henderson–Hasselbalch equation or the equilibrium-constant expression for the buffer to determine the pH.

Solve (a) *Stoichiometry Calculation:* The OH^- provided by NaOH reacts with CH_3COOH , the weak acid component of the buffer. Prior to this neutralization reaction, there are 0.300 mol each of CH_3COOH and CH_3COO^- . The amount of base added is $0.0050 \text{ L} \times 4.0 \text{ mol/L} = 0.020 \text{ mol}$. Neutralizing the 0.020 mol OH^- requires 0.020 mol of CH_3COOH . Consequently, the amount of CH_3COOH decreases by 0.020 mol, and the amount of the product of the neutralization, CH_3COO^- , increases by 0.020 mol. We can create a table to see how the composition of the buffer changes as a result of its reaction with OH^- :

Buffer before addition	0.300 mol	0	—	0.300 mol
Addition		0.020 mol	—	
Buffer after addition	0.280 mol	0	—	0.320 mol

Equilibrium Calculation: We now turn our attention to the equilibrium for the ionization of acetic acid, the relationship that determines the buffer pH:

Using the quantities of CH_3COOH and CH_3COO^- remaining in the buffer, we determine the pH using the Henderson–Hasselbalch equation. The volume of the solution is now $1.000 \text{ L} + 0.0050 \text{ L} = 1.005 \text{ L}$ due to addition of the NaOH solution:

$$\text{pH} = 4.74 + \log \frac{0.320 \text{ mol}/1.005 \text{ L}}{0.280 \text{ mol}/1.005 \text{ L}} = 4.80$$

(b) To determine the pH of a solution made by adding 0.020 mol of NaOH to 1.000 L of pure water, we first determine the concentration of OH^- ions in solution,

$$[\text{OH}^-] = 0.020 \text{ mol}/(1.005 \text{ L}) = 0.020 \text{ M}$$

We use this value in Equation 16.18 to calculate pOH and then use our calculated pOH value in Equation 16.20 to obtain pH:

$$\text{pOH} = -\log[\text{OH}^-] = -\log(0.020) = +1.70$$

$$\text{pH} = 14 - (+1.70) = 12.30$$

Comment Note that the small amount of added NaOH changes the pH of water significantly. In contrast, the pH of the buffer changes very little when the NaOH is added, as summarized in ◀ FIGURE 17.4.

PRACTICE EXERCISE

Determine (a) the pH of the original buffer described in Sample Exercise 17.5 after the addition of 0.020 mol HCl and (b) the pH of the solution that would result from the addition of 0.020 mol HCl to 1.000 L of pure water.

Answers: (a) 4.68, (b) 1.70

▲ FIGURE 17.4 Effect of adding a strong base to a buffered solution and to water.

CHEMISTRY AND LIFE

BLOOD AS A BUFFERED SOLUTION

Chemical reactions that occur in living systems are often extremely sensitive to pH. Many of the enzymes that catalyze important biochemical reactions, for example, are effective only within a narrow pH range. For this reason, the human body maintains a remarkably intricate system of buffers, both within cells and in the fluids that transport cells. Blood, the fluid that transports oxygen to all parts of the body, is one of the most prominent examples of the importance of buffers in living beings.

Human blood has a normal pH of 7.35 to 7.45. Any deviation from this range can have extremely disruptive effects on the stability of cell membranes, the structures of proteins, and the activities of enzymes. Death may result if the blood pH falls below 6.8 or rises above 7.8. When the pH falls below 7.35, the condition is called *acidosis*; when it rises above 7.45, the condition is called *alkalosis*. Acidosis is the more common tendency because metabolism generates several acids in the body.

The major buffer system used to control blood pH is the *carbonic acid–bicarbonate buffer system*. Carbonic acid (H_2CO_3) and bicarbonate ion (HCO_3^-) are a conjugate acid–base pair. In addition, carbonic acid decomposes into carbon dioxide gas and water. The important equilibria in this buffer system are

Several aspects of these equilibria are notable. First, although carbonic acid is diprotic, the carbonate ion (CO_3^{2-}) is unimportant in this system. Second, one component of this equilibrium, CO_2 , is a gas, which provides a mechanism for the body to adjust the equilibria. Removal of CO_2 via exhalation shifts the equilibria to the right, consuming H^+ ions. Third, the buffer system in blood operates at pH 7.4, which is fairly far removed from the $\text{p}K_{a1}$ value of H_2CO_3 (6.1 at physiological temperatures). For the buffer to have a pH of 7.4, the ratio $[\text{base}]/[\text{acid}]$ must be about 20. In normal blood plasma the concentrations of HCO_3^- and H_2CO_3 are about 0.024 M and 0.0012 M, respectively. Consequently, the buffer has a high capacity to neutralize additional acid but only a low capacity to neutralize additional base.

The principal organs that regulate the pH of the carbonic acid–bicarbonate buffer system are the lungs and kidneys. When the concentration of CO_2 rises, the equilibria in Equation 17.10 shift to the left, which leads to the formation of more H^+ and a drop in pH. This change is detected by receptors in the brain that trigger a reflex to breathe faster and deeper, increasing the rate at which CO_2 is expelled from the lungs and thereby shifting the equilibria back to the right. When the blood pH becomes too high, the kidneys remove HCO_3^- from the blood. This shifts the equilibria to the left, increasing the concentration of H^+ . As a result, the pH decreases.

Regulation of blood pH relates directly to the effective transport of O_2 throughout the body. The protein hemoglobin, found in red blood cells (► **FIGURE 17.5**), carries oxygen. Hemoglobin (Hb)

reversibly binds both H^+ and O_2 . These two substances compete for the Hb, which can be represented approximately by the equilibrium

Oxygen enters the blood through the lungs, where it passes into the red blood cells and binds to Hb. When the blood reaches tissue in which the concentration of O_2 is low, the equilibrium in Equation 17.11 shifts to the left and O_2 is released.

During periods of strenuous exertion, three factors work together to ensure delivery of O_2 to active tissues. The role of each factor can be understood by applying Le Châtelier's principle to Equation 17.11:

1. O_2 is consumed, causing the equilibrium to shift to the left, releasing more O_2 .
2. Large amounts of CO_2 are produced by metabolism, which increases $[\text{H}^+]$ and causes the equilibrium to shift to the left, releasing O_2 .
3. Body temperature rises. Because Equation 17.11 is exothermic, the increase in temperature shifts the equilibrium to the left, releasing O_2 .

In addition to the factors causing release of O_2 to tissues, the decrease in pH stimulates an increase in breathing rate, which furnishes more O_2 and eliminates CO_2 . Without this elaborate series of equilibrium shifts and pH changes, the O_2 in tissues would be rapidly depleted, making further activity impossible. Under such conditions the buffering capacity of the blood and the exhalation of CO_2 through the lungs are essential to keep the pH from dropping too low, thereby triggering acidosis.

17.3 ACID–BASE TITRATIONS

In an acid–base titration, a solution containing a known concentration of base is slowly added to an acid (or the acid is added to the base). ∞ (Section 4.6) Acid–base indicators can be used to signal the *equivalence point* of a titration (the point at which stoichiometrically equivalent quantities of acid and base have been brought together). Alternatively, a pH meter can be used to monitor the progress of the reaction (◀ FIGURE 17.6), producing a **pH titration curve**, a graph of the pH as a function of the volume of titrant added. The shape of the titration curve makes it possible to determine the equivalence point. The curve can also be used to select suitable indicators and to determine the K_a of the weak acid or the K_b of the weak base being titrated.

To understand why titration curves have certain characteristic shapes, we will examine the curves for three kinds of titrations: (1) strong acid–strong base, (2) weak acid–strong base, and (3) polyprotic acid–strong base. We will also briefly consider how these curves relate to those involving weak bases.

Strong Acid–Strong Base Titrations

The titration curve produced when a strong base is added to a strong acid has the general shape shown in ▼ FIGURE 17.7, which depicts the pH change that occurs as

GO FIGURE

What volume of NaOH(aq) would be needed to reach the equivalence point if the concentration of the added base were 0.200 M?

▲ FIGURE 17.7 Titration of a strong acid with a strong base. The pH curve for titration of 50.0 mL of a 0.100 M solution of hydrochloric acid with a 0.100 M solution of NaOH(aq). For clarity, water molecules have been omitted from the molecular art.

0.100 M NaOH is added to 50.0 mL of 0.100 M HCl. The pH can be calculated at various stages of the titration. To help understand these calculations, we can divide the curve into four regions:

- Initial pH:** The pH of the solution before the addition of any base is determined by the initial concentration of the strong acid. For a solution of 0.100 M HCl, $[\text{H}^+] = 0.100 \text{ M}$ and $\text{pH} = -\log(0.100) = 1.000$. Thus, the initial pH is low.
- Between initial pH and equivalence point:** As NaOH is added, the pH increases slowly at first and then rapidly in the vicinity of the equivalence point. The pH before the equivalence point is determined by the concentration of acid not yet neutralized. This calculation is illustrated in Sample Exercise 17.6(a).
- Equivalence point:** At the equivalence point an equal number of moles of NaOH and HCl have reacted, leaving only a solution of their salt, NaCl. The pH of the solution is 7.00 because the cation of a strong base (in this case Na^+) and the anion of a strong acid (in this case Cl^-) are neither acids nor bases and, therefore, have no appreciable effect on pH. ∞ (Section 16.9)
- After equivalence point:** The pH of the solution after the equivalence point is determined by the concentration of excess NaOH in the solution. This calculation is illustrated in Sample Exercise 17.6(b).

SAMPLE EXERCISE 17.6 Calculating pH for a Strong Acid–Strong Base Titration

Calculate the pH when (a) 49.0 mL and (b) 51.0 mL of 0.100 M NaOH solution have been added to 50.0 mL of 0.100 M HCl solution.

SOLUTION

Analyze We are asked to calculate the pH at two points in the titration of a strong acid with a strong base. The first point is just before the equivalence point, so we expect the pH to be determined by the small amount of strong acid that has not yet been neutralized. The second point is just after the equivalence point, so we expect this pH to be determined by the small amount of excess strong base.

Plan (a) As the NaOH solution is added to the HCl solution, $\text{H}^+(\text{aq})$ reacts with $\text{OH}^-(\text{aq})$ to form H_2O . Both Na^+ and Cl^- are spectator ions, having negligible effect on the pH. To determine the pH of the solution, we must first determine how many moles of H^+ were originally present and how many moles of OH^- were added. We can then calculate how many moles of each ion remain after the neutralization reaction. To calculate $[\text{H}^+]$, and hence pH, we must also remember that the volume of the solution increases as we add titrant, thus diluting the concentration of all solutes present.

Solve The number of moles of H^+ in the original HCl solution is given by the product of the volume of the solution and its molarity:

$$(0.0500 \text{ L soln}) \left(\frac{0.100 \text{ mol H}^+}{1 \text{ L soln}} \right) = 5.00 \times 10^{-3} \text{ mol H}^+$$

Likewise, the number of moles of OH^- in 49.0 mL of 0.100 M NaOH is

$$(0.0490 \text{ L soln}) \left(\frac{0.100 \text{ mol OH}^-}{1 \text{ L soln}} \right) = 4.90 \times 10^{-3} \text{ mol OH}^-$$

Because we have not reached the equivalence point, there are more moles of H^+ present than OH^- . Each mole of OH^- reacts with 1 mol of H^+ . Using the convention introduced in Sample Exercise 17.5, we have

	$\text{H}^+(\text{aq})$	+	$\text{OH}^-(\text{aq})$	\longrightarrow	$\text{H}_2\text{O}(\text{l})$
Before addition	$5.00 \times 10^{-3} \text{ mol}$		0		—
Addition			$4.90 \times 10^{-3} \text{ mol}$		
After addition	$0.10 \times 10^{-3} \text{ mol}$		0		—

The volume of the reaction mixture increases as the NaOH solution is added to the HCl solution. Thus, at this point in the titration, the volume in the titration flask is

$$50.0 \text{ mL} + 49.0 \text{ mL} = 99.0 \text{ mL} = 0.0990 \text{ L}$$

Thus, the concentration of $\text{H}^+(\text{aq})$ in the flask is

$$[\text{H}^+] = \frac{\text{moles H}^+(\text{aq})}{\text{liters soln}} = \frac{0.10 \times 10^{-3} \text{ mol}}{0.09900 \text{ L}} = 1.0 \times 10^{-3} \text{ M}$$

The corresponding pH is

$$-\log(1.0 \times 10^{-3}) = 3.00$$

Plan (b) We proceed in the same way as we did in part (a) except we are now past the equivalence point and have more OH^- in the solution than H^+ . As before, the initial number of moles of each reactant

is determined from their volumes and concentrations. The reactant present in smaller stoichiometric amount (the limiting reactant) is consumed completely, leaving an excess of hydroxide ion.

Solve

	$\text{H}^+(aq)$	+	$\text{OH}^-(aq)$	\longrightarrow	$\text{H}_2\text{O}(l)$
Before addition	$5.00 \times 10^{-3} \text{ mol}$		0		—
Addition			$5.10 \times 10^{-3} \text{ mol}$		
After addition	0		$0.10 \times 10^{-3} \text{ mol}$		—

In this case the volume in the titration flask is

$$50.0 \text{ mL} + 51.0 \text{ mL} = 101.0 \text{ mL} = 0.1010 \text{ L}$$

Hence, the concentration of $\text{OH}^-(aq)$ in the flask is

$$[\text{OH}^-] = \frac{\text{moles OH}^-(aq)}{\text{liters soln}} = \frac{0.10 \times 10^{-3} \text{ mol}}{0.1010 \text{ L}} = 1.0 \times 10^{-3} \text{ M}$$

and we have

$$\text{pOH} = -\log(1.0 \times 10^{-3}) = 3.00$$

$$\text{pH} = 14.00 - \text{pOH} = 14.00 - 3.00 = 11.00$$

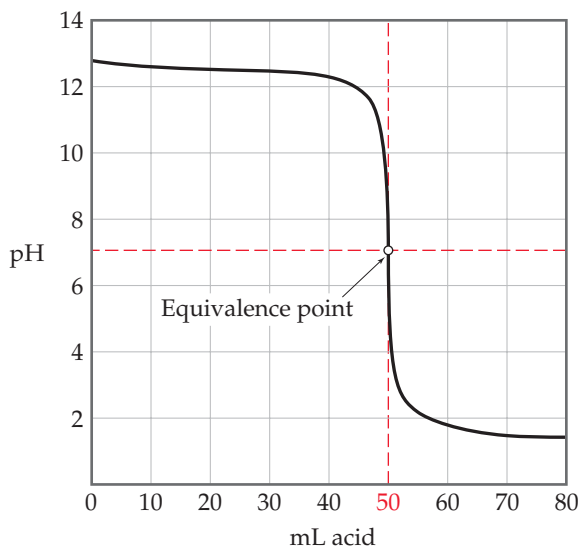

Comment Note that the pH increased by only two pH units, from 1.00 (Figure 17.7) to 3.00, after the first 49.0 mL of NaOH solution was added, but jumped by eight pH units, from 3.00 to 11.00, as

2.0 mL of base solution was added near the equivalence point. Such a rapid rise in pH near the equivalence point is a characteristic of titrations involving strong acids and strong bases.

PRACTICE EXERCISE

Calculate the pH when (a) 24.9 mL and (b) 25.1 mL of 0.100 M HNO_3 have been added to 25.0 mL of 0.100 M KOH solution.

Answers: (a) 10.30, (b) 3.70

▲ FIGURE 17.8 Titration of a strong base with a strong acid. The pH curve for titration of 50.0 mL of a 0.100 M solution of a strong base with a 0.100 M solution of a strong acid.

Titration of a solution of a strong base with a solution of a strong acid yields an analogous curve of pH versus added acid. In this case, however, the pH is high at the outset of the titration and low at its completion (◀ **FIGURE 17.8**).

▲ GIVE IT SOME THOUGHT

What is the pH at the equivalence point when 0.10 M HNO_3 is used to titrate a volume of solution containing 0.30 g of KOH?

Weak Acid–Strong Base Titrations

The curve for titration of a weak acid by a strong base is similar to the curve in Figure 17.7. Consider, for example, the curve for titration of 50.0 mL of 0.100 M acetic acid with 0.100 M NaOH shown in ▶ **FIGURE 17.9**. We can calculate the pH at points along this curve, using principles we discussed earlier, which means again dividing the curve into four regions:

- 1. Initial pH:** We use K_a to calculate this pH, as shown in Section 16.6. The calculated pH of 0.100 M CH_3COOH is 2.89.
- 2. Between initial pH and equivalence point:** Prior to reaching the equivalence point, the acid is being neutralized, and its conjugate base is being formed:

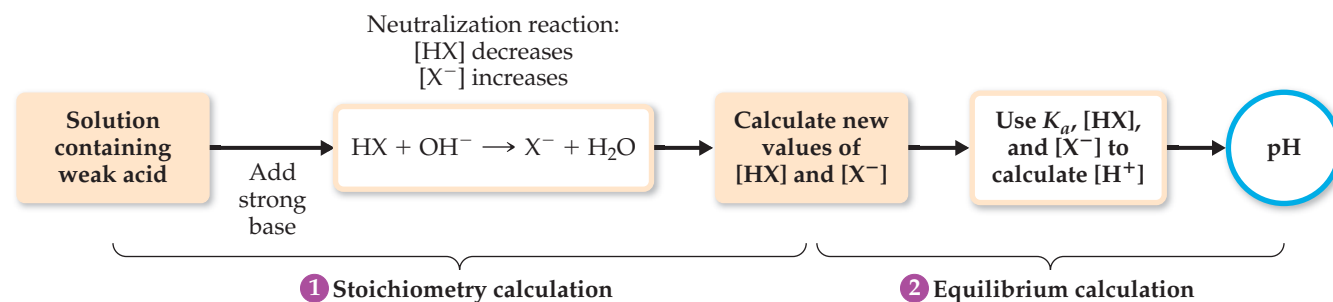

Thus, the solution contains a mixture of CH_3COOH and CH_3COO^- . Calculating the pH in this region involves two steps. First, we consider the neutralization reaction between CH_3COOH and OH^- to determine $[\text{CH}_3\text{COOH}]$ and $[\text{CH}_3\text{COO}^-]$. Next, we calculate the pH of this buffer pair using procedures developed in Sections 17.1 and 17.2. The general procedure is diagrammed in ▶ **FIGURE 17.10** and illustrated in Sample Exercise 17.7.

GO FIGURE

If the acetic acid being titrated here were replaced by hydrochloric acid, would the amount of base needed to reach the equivalence point change? Would the pH at the equivalence point change?

▲ FIGURE 17.9 Titration of a weak acid with a strong base. The pH curve for titration of 50.0 mL of a 0.100 M solution of acetic acid with a 0.100 M solution of $\text{NaOH}(aq)$. For clarity, water molecules have been omitted from the molecular art.

▲ FIGURE 17.10 Procedure for calculating pH when a weak acid is partially neutralized by a strong base.

- 3. Equivalence point:** The equivalence point is reached when 50.0 mL of 0.100 M NaOH has been added to the 50.0 mL of 0.100 M CH₃COOH. At this point, the 5.00×10^{-3} mol of NaOH completely reacts with the 5.00×10^{-3} mol of CH₃COOH to form 5.00×10^{-3} mol of CH₃COONa. The Na⁺ ion of this salt has no significant effect on the pH. The CH₃COO⁻ ion, however, is a weak base, and the pH at the equivalence point is therefore greater than 7. In general, the pH at the equivalence point is always above 7 in a weak acid–strong base titration because the anion of the salt formed is a weak base. The procedure for calculating the pH of the solution of a weak base is described in Section 16.7 and is shown in Sample Exercise 17.8.
- 4. After equivalence point (excess base):** In this region, [OH⁻] from the reaction of CH₃COO⁻ with water is negligible relative to [OH⁻] from the excess NaOH. Thus, the pH is determined by the concentration of OH⁻ from the excess NaOH. The method for calculating pH in this region is therefore like that illustrated in Sample Exercise 17.6(b). Thus, the addition of 51.0 mL of 0.100 M NaOH to 50.0 mL of either 0.100 M HCl or 0.100 M CH₃COOH yields the same pH, 11.00. Notice by comparing Figures 17.7 and 17.9 that the titration curves for a strong acid and a weak acid are the same after the equivalence point.

SAMPLE EXERCISE 17.7 Calculating pH for a Weak Acid–Strong Base Titration

Calculate the pH of the solution formed when 45.0 mL of 0.100 M NaOH is added to 50.0 mL of 0.100 M CH₃COOH ($K_a = 1.8 \times 10^{-5}$).

SOLUTION

Analyze We are asked to calculate the pH before the equivalence point of the titration of a weak acid with a strong base.

Plan We first must determine the number of moles of CH₃COOH and CH₃COO⁻ present after the neutralization reaction. We then calculate pH using K_a , [CH₃COOH], and [CH₃COO⁻].

Solve *Stoichiometry Calculation:* The product of the volume and concentration of each solution gives the number of moles of each reactant present before the neutralization:

$$(0.0500 \text{ L soln}) \left(\frac{0.100 \text{ mol CH}_3\text{COOH}}{1 \text{ L soln}} \right) = 5.00 \times 10^{-3} \text{ mol CH}_3\text{COOH}$$

$$(0.0450 \text{ L soln}) \left(\frac{0.100 \text{ mol NaOH}}{1 \text{ L soln}} \right) = 4.50 \times 10^{-3} \text{ mol NaOH}$$

The 4.50×10^{-3} of NaOH consumes 4.50×10^{-3} of CH₃COOH:

Before addition	5.00×10^{-3} mol	0	0	—
Addition		4.50×10^{-3} mol		
After addition	0.50×10^{-3} mol	0	4.50×10^{-3} mol	—

The total volume of the solution is

$$45.0 \text{ mL} + 50.0 \text{ mL} = 95.0 \text{ mL} = 0.0950 \text{ L}$$

The resulting molarities of CH₃COOH and CH₃COO⁻ after the reaction are therefore

$$[\text{CH}_3\text{COOH}] = \frac{0.50 \times 10^{-3} \text{ mol}}{0.0950 \text{ L}} = 0.0053 \text{ M}$$

$$[\text{CH}_3\text{COO}^-] = \frac{4.50 \times 10^{-3} \text{ mol}}{0.0950 \text{ L}} = 0.0474 \text{ M}$$

Equilibrium Calculation: The equilibrium between CH₃COOH and CH₃COO⁻ must obey the equilibrium-constant expression for CH₃COOH:

$$K_a = \frac{[\text{H}^+][\text{CH}_3\text{COO}^-]}{[\text{CH}_3\text{COOH}]} = 1.8 \times 10^{-5}$$

Solving for $[H^+]$ gives

$$[H^+] = K_a \times \frac{[CH_3COOH]}{[CH_3COO^-]} = (1.8 \times 10^{-5}) \times \left(\frac{0.0053}{0.0474} \right) = 2.0 \times 10^{-6} M$$

$$pH = -\log(2.0 \times 10^{-6}) = 5.70$$

Comment We could have solved for pH equally well using the Henderson–Hasselbalch equation.

PRACTICE EXERCISE

(a) Calculate the pH in the solution formed by adding 10.0 mL of 0.050 M NaOH to 40.0 mL of 0.0250 M benzoic acid (C_6H_5COOH , $K_a = 6.3 \times 10^{-5}$). (b) Calculate the pH in the solution formed by adding 10.0 mL of 0.100 M HCl to 20.0 mL of 0.100 M NH_3 .

Answers: (a) 4.20, (b) 9.26

In order to follow the evolution of pH as a function of added base further, we can calculate the pH at the equivalence point.

SAMPLE EXERCISE 17.8 Calculating the pH at the Equivalence Point

Calculate the pH at the equivalence point in the titration of 50.0 mL of 0.100 M CH_3COOH with 0.100 M NaOH.

SOLUTION

Analyze We are asked to determine the pH at the equivalence point of the titration of a weak acid with a strong base. Because the neutralization of a weak acid produces its anion, which is a weak base, we expect the pH at the equivalence point to be greater than 7.

Plan The initial number of moles of acetic acid equals the number of moles of acetate ion at the equivalence point. We use the volume of the solution at the equivalence point to calculate the concentration of acetate ion. Because the acetate ion is a weak base, we can calculate the pH using K_b and $[CH_3COO^-]$.

Solve The number of moles of acetic acid in the initial solution is obtained from the volume and molarity of the solution:

$$\text{Moles} = M \times L = (0.100 \text{ mol/L}) / (0.0500 \text{ L}) = 5.00 \times 10^{-3} \text{ mol } CH_3COOH$$

Hence, 5.00×10^{-3} mol of $[CH_3COO^-]$ is formed. It will take 50.0 mL of NaOH to reach the equivalence point (Figure 17.9). The volume of this salt solution at the equivalence point is the sum of the volumes of the acid and base, 50.0 mL + 50.0 mL = 100.0 mL = 0.1000 L. Thus, the concentration of CH_3COO^- is

$$[CH_3COO^-] = \frac{5.00 \times 10^{-3} \text{ mol}}{0.1000 \text{ L}} = 0.0500 M$$

The CH_3COO^- ion is a weak base:

The K_b for CH_3COO^- can be calculated from the K_a value of its conjugate acid, $K_b = K_w/K_a = (1.0 \times 10^{-14}) / (1.8 \times 10^{-5}) = 5.6 \times 10^{-10}$. Using the K_b expression, we have

$$K_b = \frac{[CH_3COOH][OH^-]}{[CH_3COO^-]} = \frac{(x)(x)}{0.0500 - x} = 5.6 \times 10^{-10}$$

Making the approximation that $0.0500 - x \approx 0.0500$, and then solving for x , we have $x = [OH^-] = 5.3 \times 10^{-6} M$, which gives $pOH = 5.28$ and $pH = 8.72$.

Check The pH is above 7, as expected for the salt of a weak acid and strong base.

PRACTICE EXERCISE

Calculate the pH at the equivalence point when (a) 40.0 mL of 0.025 M benzoic acid (C_6H_5COOH , $K_a = 6.3 \times 10^{-5}$) is titrated with 0.050 M NaOH; (b) 40.0 mL of 0.100 M NH_3 is titrated with 0.100 M HCl.

Answers: (a) 8.21, (b) 5.28

GO FIGURE

How does the pH at the equivalence point change as the acid being titrated becomes weaker? How does the volume of NaOH(aq) needed to reach the equivalence point change?

▲ **FIGURE 17.11** A set of curves showing the effect of acid strength on the characteristics of the titration curve when a weak acid is titrated by a strong base. Each curve represents titration of 50.0 mL of 0.10 M acid with 0.10 M NaOH.

The titration curve for a weak acid–strong base titration (Figure 17.9) differs from the curve for a strong acid–strong base titration (Figure 17.7) in three noteworthy ways:

1. The solution of the weak acid has a higher initial pH than a solution of a strong acid of the same concentration.
2. The pH change in the rapid-rise portion of the curve near the equivalence point is smaller for the weak acid than for the strong acid.
3. The pH at the equivalence point is above 7.00 for the weak acid titration.

The weaker the acid, the more pronounced these differences become. To illustrate this consider the family of titration curves shown in ◀ **FIGURE 17.11**. Notice that as the acid becomes weaker (that is, as K_a becomes smaller), the initial pH increases and the pH change near the equivalence point becomes less marked. Furthermore, the pH at the equivalence point steadily increases as K_a decreases, because the strength of the conjugate base of the weak acid increases. It is virtually impossible to determine the equivalence point when pK_a is 10 or higher because the pH change is too small and gradual.

Titration of Polyprotic Acids

When weak acids contain more than one ionizable H atom, the reaction with OH^- occurs in a series of steps. Neutralization of H_3PO_3 , for example, proceeds in two steps (Chapter 16 Sample Integrative Exercise):

When the neutralization steps of a polyprotic acid or polybasic base are sufficiently separated, the titration has multiple equivalence points. ▼ **FIGURE 17.12** shows the two equivalence points corresponding to Equations 17.13 and 17.14.

► **FIGURE 17.12** Titration curve for a diprotic acid. The curve shows the pH change when 50.0 mL of 0.10 M H_3PO_3 is titrated with 0.10 M NaOH.

GIVE IT SOME THOUGHT

Sketch an approximate titration curve for the titration of Na_2CO_3 with HCl .

Titrating with an Acid–Base Indicator

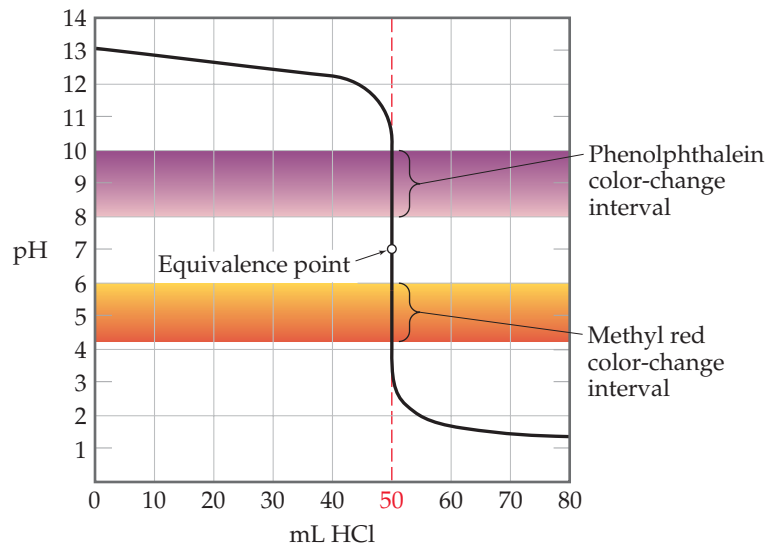

Often in an acid–base titration, an indicator is used rather than a pH meter. Optimally, an indicator should change color at the equivalence point in a titration. In practice, however, that is unnecessary. The pH changes very rapidly near the equivalence point, and in this region one drop of titrant can change the pH by several units. Thus, an indicator beginning and ending its color change anywhere on the rapid-rise portion of the titration curve gives a sufficiently accurate measure of the titrant volume needed to reach the equivalence point. The point in a titration where the indicator changes color is called the *end point* to distinguish it from the equivalence point that it closely approximates.

► **FIGURE 17.13** shows the curve for titration of a strong base (NaOH) with a strong acid (HCl). We see from the vertical part of the curve that the pH changes rapidly from roughly 11 to 3 near the equivalence point. Consequently, an indicator for this titration can change color anywhere in this range. Most strong acid–strong base titrations are carried out using phenolphthalein as an indicator because it changes color in this range (see Figure 16.8, page 664). Several other indicators would also be satisfactory, including methyl red, which, as the lower color band in Figure 17.13 shows, changes color in the pH range from about 4.2 to 6.0. (see Figure 16.8, page 664).

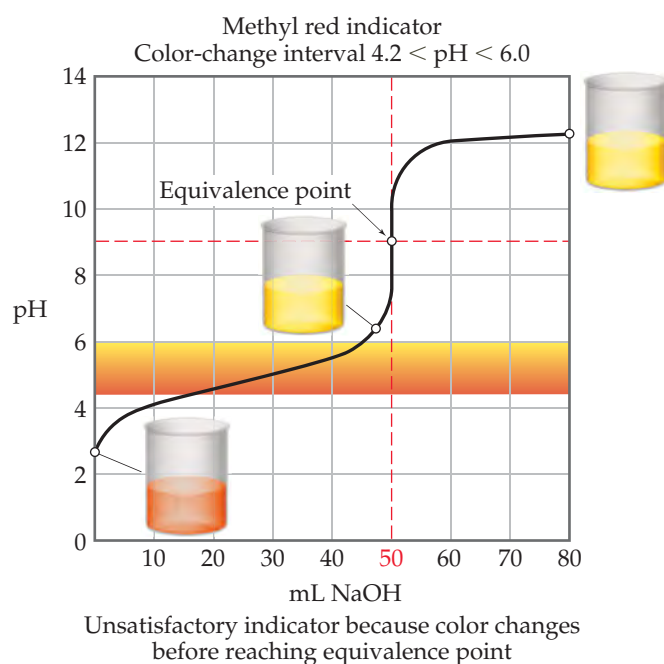

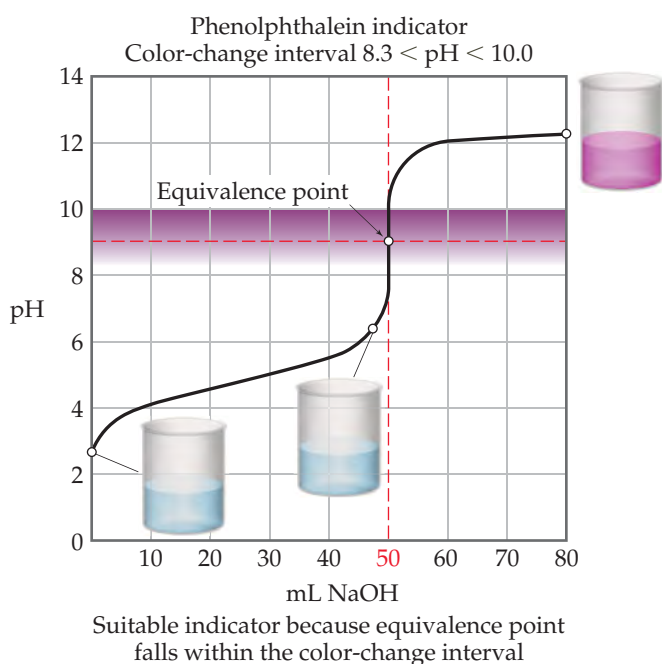

As noted in our discussion of Figure 17.11, because the pH change near the equivalence point becomes smaller as K_a decreases, the choice of indicator for a weak acid–strong base titration is more critical than it is for titrations where both acid and base are strong. When $0.100\text{ M CH}_3\text{COOH}$ ($K_a = 1.8 \times 10^{-5}$) is titrated with 0.100 M NaOH , for example, the pH increases rapidly only over the pH range from about 7 to 11 (▼ **FIGURE 17.14**). Phenolphthalein is therefore an ideal indicator because it changes

GO FIGURE

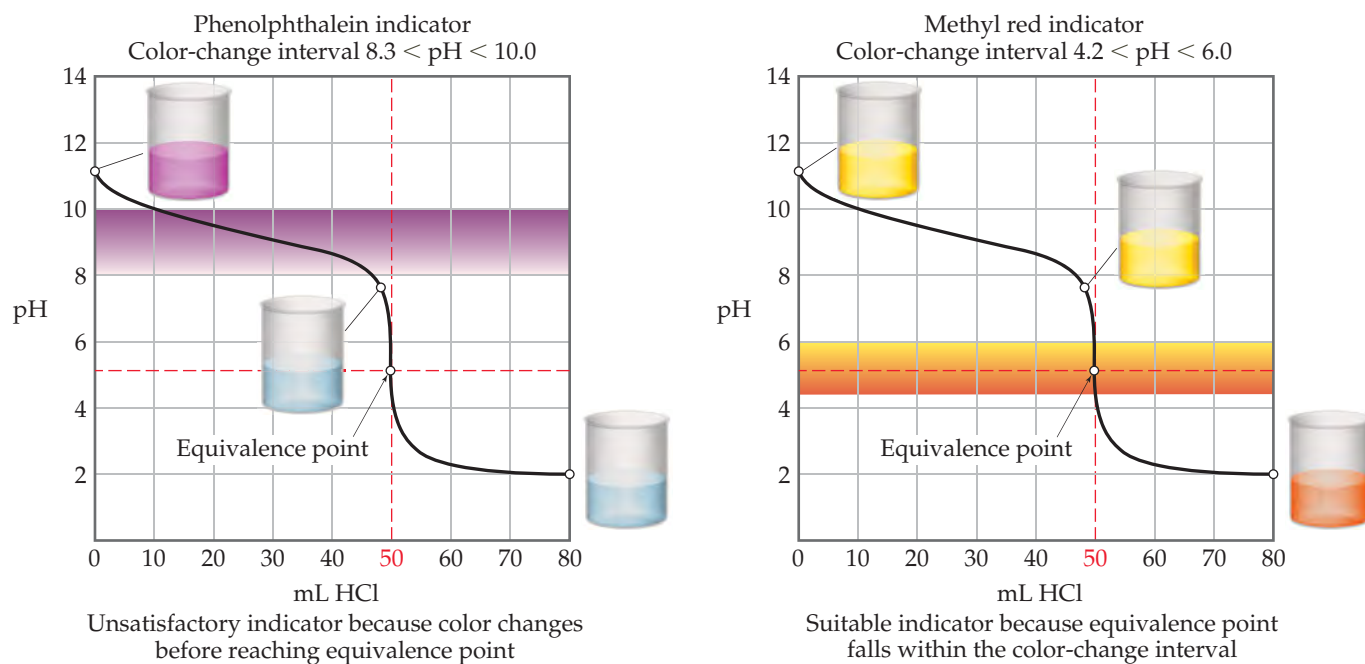

Is methyl red a suitable indicator when you are titrating a strong acid with a strong base? Explain your answer.

▲ **FIGURE 17.13** Using color indicators for titration of a strong base with a strong acid. Both phenolphthalein and methyl red change color in the rapid-rise portion of the titration curve.

▲ **FIGURE 17.14** Good and poor indicators for titration of a weak acid with a strong base.

▲ **FIGURE 17.15** Good and poor indicators for titration of a weak base with a strong acid.

color from pH 8.3 to 10.0, close to the pH at the equivalence point. Methyl red is a poor choice, however, because its color change, from 4.2 to 6.0, begins well before the equivalence point is reached.

Titration of a weak base (such as 0.100 M NH_3) with a strong acid solution (such as 0.100 M HCl) leads to the titration curve shown in ▲ **FIGURE 17.15**. In this example, the equivalence point occurs at pH 5.28. Thus, methyl red is an ideal indicator but phenolphthalein would be a poor choice.

▲ GIVE IT SOME THOUGHT

Why is the choice of indicator more crucial for a weak acid–strong base titration than for a strong acid–strong base titration?

17.4 SOLUBILITY EQUILIBRIA

The equilibria we have considered thus far in this chapter have involved acids and bases. Furthermore, they have been homogeneous; that is, all the species have been in the same phase. Through the rest of the chapter, we will consider the equilibria involved in the dissolution or precipitation of ionic compounds. These reactions are heterogeneous.

Dissolution and precipitation occur both within us and around us. Tooth enamel dissolves in acidic solutions, for example, causing tooth decay, and the precipitation of certain salts in our kidneys produces kidney stones. The waters of Earth contain salts dissolved as water passes over and through the ground. Precipitation of CaCO_3 from groundwater is responsible for the formation of stalactites and stalagmites within limestone caves.

In our earlier discussion of precipitation reactions, we considered general rules for predicting the solubility of common salts in water. ∞ (Section 4.2) These rules give us a qualitative sense of whether a compound has a low or high solubility in water. By considering solubility equilibria, however, we can make quantitative predictions about solubility.

The Solubility-Product Constant, K_{sp}

Recall that a *saturated solution* is one in which the solution is in contact with undissolved solute. ∞ (Section 13.2) Consider, for example, a saturated aqueous solution of

BaSO₄ in contact with solid BaSO₄. Because the solid is an ionic compound, it is a strong electrolyte and yields Ba²⁺(aq) and SO₄²⁻(aq) ions when dissolved in water, readily establishing the equilibrium

As with any other equilibrium, the extent to which this dissolution reaction occurs is expressed by the magnitude of the equilibrium constant. Because this equilibrium equation describes the dissolution of a solid, the equilibrium constant indicates how soluble the solid is in water and is referred to as the **solubility-product constant** (or simply the **solubility product**). It is denoted K_{sp} , where *sp* stands for solubility product.

The equilibrium-constant expression for the equilibrium between a solid and an aqueous solution of its component ions is written according to the rules that apply to any other equilibrium-constant expression. Remember, however, that solids do not appear in the equilibrium-constant expressions for heterogeneous equilibrium. ∞ (Section 15.4) Thus, the solubility-product expression for BaSO₄, which is based on Equation 17.15, is

$$K_{sp} = [\text{Ba}^{2+}][\text{SO}_4^{2-}] \quad [17.16]$$

In general, *the solubility product K_{sp} of a compound equals the product of the concentration of the ions involved in the equilibrium, each raised to the power of its coefficient in the equilibrium equation.* The coefficient for each ion in the equilibrium equation also equals its subscript in the compound's chemical formula.

The values of K_{sp} at 25 °C for many ionic solids are tabulated in Appendix D. The value of K_{sp} for BaSO₄ is 1.1×10^{-10} , a very small number indicating that only a very small amount of the solid dissolves in 25 °C water.

SAMPLE EXERCISE 17.9 Writing Solubility-Product (K_{sp}) Expressions

Write the expression for the solubility-product constant for CaF₂, and look up the corresponding K_{sp} value in Appendix D.

SOLUTION

Analyze We are asked to write an equilibrium-constant expression for the process by which CaF₂ dissolves in water.

Plan We apply the general rules for writing an equilibrium-constant expression, excluding the solid reactant from the expression. We assume that the compound dissociates completely into its component ions:

Solve The expression for K_{sp} is

$$K_{sp} = [\text{Ca}^{2+}][\text{F}^{-}]^2$$

Appendix D gives 3.9×10^{-11} for this K_{sp} .

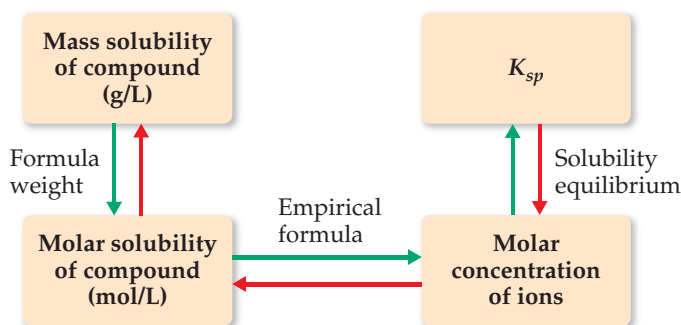

PRACTICE EXERCISE

Give the solubility-product-constant expressions and K_{sp} values (from Appendix D) for (a) barium carbonate, (b) silver sulfate.

Answers: (a) $K_{sp} = [\text{Ba}^{2+}][\text{CO}_3^{2-}] = 5.0 \times 10^{-9}$, (b) $K_{sp} = [\text{Ag}^+]^2[\text{SO}_4^{2-}] = 1.5 \times 10^{-5}$

Solubility and K_{sp}

It is important to distinguish carefully between solubility and the solubility-product constant. The solubility of a substance is the quantity that dissolves to form a saturated solution. ∞ (Section 13.2) Solubility is often expressed as grams of solute per liter of solution (g/L). *Molar solubility* is the number of moles of solute that dissolve in forming 1 L of saturated solution of the solute (mol/L). The solubility-product constant (K_{sp}) is the equilibrium constant for the equilibrium between an ionic solid and its saturated solution and is a unitless number. Thus, the magnitude of K_{sp} is a measure of how much of the solid dissolves to form a saturated solution.

▲ FIGURE 17.16 Procedure for converting between solubility and K_{sp} . Starting from the mass solubility, follow the green arrows to determine K_{sp} . Starting from K_{sp} , follow the red arrows to determine either molar solubility or mass solubility.

▲ GIVE IT SOME THOUGHT

Without doing a calculation, predict which of these compounds has the greatest molar solubility in water: AgCl ($K_{sp} = 1.8 \times 10^{-10}$), AgBr ($K_{sp} = 5.0 \times 10^{-13}$), or AgI ($K_{sp} = 8.3 \times 10^{-17}$).

The solubility of a substance can change considerably in response to a number of factors. For example, the solubilities of hydroxide salts, like $\text{Mg}(\text{OH})_2$, are dependent upon the pH of the solution. The solubility is also affected by concentrations of other ions in solution, especially common ions. In other words, the numeric value of the solubility of a given solute can and does change as the other species in solution change. In contrast, the solubility-product constant, K_{sp} , has only one value for a given solute at any specific temperature.* **▲ FIGURE 17.16** summarizes the relationships among various expressions of solubility and K_{sp} .

SAMPLE EXERCISE 17.10 Calculating K_{sp} from Solubility

Solid silver chromate is added to pure water at 25 °C, and some of the solid remains undissolved. The mixture is stirred for several days to ensure that equilibrium is achieved between the undissolved $\text{Ag}_2\text{CrO}_4(s)$ and the solution. Analysis of the equilibrated solution shows that its silver ion concentration is $1.3 \times 10^{-4} \text{ M}$. Assuming that Ag_2CrO_4 dissociates completely in water and that there are no other important equilibria involving Ag^+ or CrO_4^{2-} ions in the solution, calculate K_{sp} for this compound.

SOLUTION

Analyze We are given the equilibrium concentration of Ag^+ in a saturated solution of Ag_2CrO_4 and asked to determine the value of K_{sp} for Ag_2CrO_4 .

Plan The equilibrium equation and the expression for K_{sp} are

To calculate K_{sp} , we need the equilibrium concentrations of Ag^+ and CrO_4^{2-} . We know that at equilibrium $[\text{Ag}^+] = 1.3 \times 10^{-4} \text{ M}$. All the Ag^+ and CrO_4^{2-} ions in the solution come from the Ag_2CrO_4 that dissolves. Thus, we can use $[\text{Ag}^+]$ to calculate $[\text{CrO}_4^{2-}]$.

Solve From the chemical formula of silver chromate, we know that there must be 2 Ag^+ ions in solution for each CrO_4^{2-} ion in solution. Consequently, the concentration of CrO_4^{2-} is half the concentration of Ag^+ :

$$[\text{CrO}_4^{2-}] = \left(\frac{1.3 \times 10^{-4} \text{ mol Ag}^+}{\text{L}} \right) \left(\frac{1 \text{ mol CrO}_4^{2-}}{2 \text{ mol Ag}^+} \right) = 6.5 \times 10^{-5} \text{ M}$$

and K_{sp} is

$$K_{sp} = [\text{Ag}^+]^2[\text{CrO}_4^{2-}] = (1.3 \times 10^{-4})^2(6.5 \times 10^{-5}) = 1.1 \times 10^{-12}$$

Check We obtain a small value, as expected for a slightly soluble salt. Furthermore, the calculated value agrees well with the one given in Appendix D, 1.2×10^{-12} .

PRACTICE EXERCISE

A saturated solution of $\text{Mg}(\text{OH})_2$ in contact with undissolved $\text{Mg}(\text{OH})_2(s)$ is prepared at 25 °C. The pH of the solution is found to be 10.17. Assuming that $\text{Mg}(\text{OH})_2$ dissociates completely in water and that there are no other simultaneous equilibria involving the Mg^{2+} or OH^- ions, calculate K_{sp} for this compound.

Answer: 1.6×10^{-12}

*This is strictly true only for very dilute solutions, for K_{sp} values change somewhat when the concentration of ionic substances in water is increased. However, we will ignore these effects, which are taken into consideration only for work that requires exceptional accuracy.

In principle, it is possible to use the K_{sp} value of a salt to calculate solubility under a variety of conditions. In practice, great care must be taken in doing so for the reasons indicated in “A Closer Look: Limitations of Solubility Products” at the end of this section. Agreement between the measured solubility and that calculated from K_{sp} is usually best for salts whose ions have low charges (1+ and 1−) and do not hydrolyze.

SAMPLE EXERCISE 17.11 Calculating Solubility from K_{sp}

The K_{sp} for CaF_2 is 3.9×10^{-11} at 25 °C. Assuming that CaF_2 dissociates completely upon dissolving and that there are no other important equilibria affecting its solubility, calculate the solubility of CaF_2 in grams per liter.

SOLUTION

Analyze We are given K_{sp} for CaF_2 and asked to determine solubility. Recall that the solubility of a substance is the quantity that can dissolve in solvent, whereas the solubility-product constant, K_{sp} , is an equilibrium constant.

Plan To go from K_{sp} to solubility, we follow the steps indicated by the red arrows in Figure 17.16. We first write the chemical equation for the dissolution and set up a table of initial and equilibrium concentrations. We then use the equilibrium-constant expression. In this case

we know K_{sp} , and so we solve for the concentrations of the ions in solution. Once we know these concentrations, we use the formula weight to determine solubility in g/L.

Solve Assume that initially no salt has dissolved, and then allow x mol/L of CaF_2 to dissociate completely when equilibrium is achieved:

	$\text{CaF}_2(s)$	\rightleftharpoons	$\text{Ca}^{2+}(aq)$	+	$2\text{F}^{-}(aq)$
Initial	—		0		0
Change	—		$+x M$		$+2x M$
Equilibrium	—		$x M$		$2x M$

The stoichiometry of the equilibrium dictates that $2x$ mol/L of F^{-} are produced for each x mol/L of CaF_2 that dissolve. We now use the expression for K_{sp} and substitute the equilibrium concentrations to solve for the value of x :

$$K_{sp} = [\text{Ca}^{2+}][\text{F}^{-}]^2 = (x)(2x)^2 = 4x^3 = 3.9 \times 10^{-11}$$

(Remember that $\sqrt[3]{y} = y^{1/3}$. To calculate the cube root of a number, use the y^x function on your calculator, with $x = \frac{1}{3}$.) Thus, the molar solubility of CaF_2 is 2.1×10^{-4} mol/L.

$$x = \sqrt[3]{\frac{3.9 \times 10^{-11}}{4}} = 2.1 \times 10^{-4}$$

The mass of CaF_2 that dissolves in water to form 1 L of solution is

$$\left(\frac{2.1 \times 10^{-4} \text{ mol CaF}_2}{1 \text{ L soln}}\right)\left(\frac{78.1 \text{ g CaF}_2}{1 \text{ mol CaF}_2}\right) = 1.6 \times 10^{-2} \text{ g CaF}_2/\text{L soln}$$

Check We expect a small number for the solubility of a slightly soluble salt. If we reverse the calculation, we should be able to recalculate the solubility product: $K_{sp} = (2.1 \times 10^{-4})(4.2 \times 10^{-4})^2 = 3.7 \times 10^{-11}$, close to the value given in the problem statement, 3.9×10^{-11} .

Comment Because F^{-} is the anion of a weak acid, you might expect hydrolysis of the ion to affect the solubility of CaF_2 . The basicity of F^{-} is so small ($K_b = 1.5 \times 10^{-11}$), however, that the hydrolysis occurs to only a slight extent and does not significantly influence the solubility. The reported solubility is 0.017 g/L at 25 °C, in good agreement with our calculation.

PRACTICE EXERCISE

The K_{sp} for LaF_3 is 2×10^{-19} . What is the solubility of LaF_3 in water in moles per liter?

Answer: 9×10^{-6} mol/L

A CLOSER LOOK

LIMITATIONS OF SOLUBILITY PRODUCTS

Ion concentrations calculated from K_{sp} values sometimes deviate appreciably from those found experimentally. In part, these deviations are due to electrostatic interactions between ions in solution, which can lead to ion pairs. (See Section 13.5, “A Closer Look: Colligative Properties of Electrolyte Solutions.”) These interactions increase in magnitude both as the concentrations of the ions increase and as their charges increase. The solubility calculated from K_{sp} tends to be low unless corrected to account for these interactions.

As an example of the effect of these interactions, consider CaCO_3 (calcite), whose solubility product, $K_{sp} = 4.5 \times 10^{-9}$, gives a calculated solubility of 6.7×10^{-5} mol/L, and correcting for ionic interactions in the solution yields 7.3×10^{-5} mol/L. The reported solubility, however, is 1.4×10^{-4} mol/L, indicating that there must be additional factors involved.

Another common source of error in calculating ion concentrations from K_{sp} is ignoring other equilibria that occur simultaneously in the solution. It is possible, for example, that acid–base equilibria take place simultaneously with solubility equilibria. In particular, both basic anions and cations with high charge-to-size ratios undergo hydrolysis reactions that can measurably increase the solubilities of their salts. For example, CaCO_3 contains the basic carbonate ion ($K_b = 1.8 \times 10^{-4}$), which hydrolyzes in water:

If we consider the effect of ion-ion interactions as well as simultaneous solubility and hydrolysis equilibria, we calculate a solubility of 1.4×10^{-4} mol/L, in agreement with the measured value.

Finally, we generally assume that ionic compounds dissociate completely when they dissolve, but this assumption is not always valid. When MgF_2 dissolves, for example, it yields not only Mg^{2+} and F^- ions but also MgF^+ ions.

17.5 FACTORS THAT AFFECT SOLUBILITY

Solubility is affected by temperature and by the presence of other solutes. The presence of an acid, for example, can have a major influence on the solubility of a substance. In Section 17.4 we considered the dissolving of ionic compounds in pure water. In this section we examine three factors that affect the solubility of ionic compounds: (1) presence of common ions, (2) solution pH, and (3) presence of complexing agents. We will also examine the phenomenon of *amphoterism*, which is related to the effects of both pH and complexing agents.

▲ **FIGURE 17.17** Common-ion effect. Notice that the CaF_2 solubility is on a logarithmic scale.

Common-Ion Effect

The presence of either $\text{Ca}^{2+}(aq)$ or $\text{F}^-(aq)$ in a solution reduces the solubility of CaF_2 , shifting the solubility equilibrium to the left:

← Addition of Ca^{2+} or F^- shifts equilibrium, reducing solubility

This reduction in solubility is another manifestation of the common-ion effect we looked at in Section 17.1. In general, *the solubility of a slightly soluble salt is decreased by the presence of a second solute that furnishes a common ion*, as ◀ **FIGURE 17.17** shows for CaF_2 .

SAMPLE EXERCISE 17.12 Calculating the Effect of a Common Ion on Solubility

Calculate the molar solubility of CaF_2 at 25 °C in a solution that is (a) 0.010 M in $\text{Ca}(\text{NO}_3)_2$, (b) 0.010 M in NaF.

SOLUTION

Analyze We are asked to determine the solubility of CaF_2 in the presence of two strong electrolytes, each containing an ion common to CaF_2 . In (a) the common ion is Ca^{2+} , and NO_3^- is a spectator ion. In (b) the common ion is F^- , and Na^+ is a spectator ion.

Plan Because the slightly soluble compound is CaF_2 , we need to use K_{sp} for this compound, which Appendix D gives as 3.9×10^{-11} . The value of K_{sp} is unchanged by the presence of additional solutes. Because of the common-ion effect, however, the solubility of the salt decreases in the presence of common ions. We use our standard equilibrium techniques of starting with the equation for CaF_2 dissolution, setting up a table of initial and equilibrium concentrations, and using the K_{sp} expression to determine the concentration of the ion that comes only from CaF_2 .

Solve

(a) The initial concentration of Ca^{2+} is 0.010 M because of the dissolved $\text{Ca}(\text{NO}_3)_2$:

Initial	—	0.010 M	0
Change	—	+x M	+2x M
Equilibrium	—	(0.010 + x) M	2x M

Substituting into the solubility-product expression gives

$$K_{sp} = 3.9 \times 10^{-11} = [\text{Ca}^{2+}][\text{F}^-]^2 = (0.010 + x)(2x)^2$$

This would be a messy problem to solve exactly, but fortunately it is possible to simplify matters. Even without the common-ion effect, the solubility of CaF_2 is very small (2.1×10^{-4} M). Thus, we assume that the 0.010 M concentration of Ca^{2+} from $\text{Ca}(\text{NO}_3)_2$ is very much greater than the small additional concentration resulting from the solubility of CaF_2 ; that is, x is much smaller than 0.010 M, and $0.010 + x \approx 0.010$. We then have

$$\begin{aligned} 3.9 \times 10^{-11} &= (0.010)(2x)^2 \\ x^2 &= \frac{3.9 \times 10^{-11}}{4(0.010)} = 9.8 \times 10^{-10} \\ x &= \sqrt{9.8 \times 10^{-10}} = 3.1 \times 10^{-5} \text{ M} \end{aligned}$$

This very small value for x validates the simplifying assumption we made. Our calculation indicates that 3.1×10^{-5} mol of solid CaF_2 dissolves per liter of 0.010 M $\text{Ca}(\text{NO}_3)_2$ solution.

(b) The common ion is F^- , and at equilibrium we have

$$[\text{Ca}^{2+}] = x \quad \text{and} \quad [\text{F}^-] = 0.010 + 2x$$

Assuming that $2x$ is much smaller than 0.010 M (that is, $0.010 + 2x \approx 0.010$), we have

$$\begin{aligned} 3.9 \times 10^{-11} &= (x)(0.010 + 2x)^2 \approx x(0.010)^2 \\ x &= \frac{3.9 \times 10^{-11}}{(0.010)^2} = 3.9 \times 10^{-7} \text{ M} \end{aligned}$$

Thus, 3.9×10^{-7} mol of solid CaF_2 should dissolve per liter of 0.010 M NaF solution.

Comment The molar solubility of CaF_2 in water is 2.1×10^{-4} M (Sample Exercise 17.11). By comparison, our calculations here give a CaF_2 solubility of 3.1×10^{-5} M in the presence of 0.010 M Ca^{2+} and 3.9×10^{-7} M in the presence of 0.010 M F^- ion. Thus, the addition

of either Ca^{2+} or F^- to a solution of CaF_2 decreases the solubility. However, the effect of F^- on the solubility is more pronounced than that of Ca^{2+} because $[\text{F}^-]$ appears to the second power in the K_{sp} expression for CaF_2 , whereas $[\text{Ca}^{2+}]$ appears to the first power.

PRACTICE EXERCISE

For manganese(II) hydroxide, $\text{Mn}(\text{OH})_2$, $K_{sp} = 1.6 \times 10^{-13}$. Calculate the molar solubility of $\text{Mn}(\text{OH})_2$ in a solution that contains 0.020 M NaOH.

Answer: 4.0×10^{-10} M

Solubility and pH

The pH of a solution affects the solubility of any substance whose anion is basic. Consider $\text{Mg}(\text{OH})_2$, for which the solubility equilibrium is

A saturated solution of $\text{Mg}(\text{OH})_2$ has a calculated pH of 10.52 and its Mg^{2+} concentration is $1.7 \times 10^{-4} \text{ M}$. Now suppose that solid $\text{Mg}(\text{OH})_2$ is equilibrated with a solution buffered at pH 9.0. The pOH, therefore, is 5.0, so $[\text{OH}^-] = 1.0 \times 10^{-5}$. Inserting this value for $[\text{OH}^-]$ into the solubility-product expression, we have

$$K_{sp} = [\text{Mg}^{2+}][\text{OH}^-]^2 = 1.8 \times 10^{-11}$$

$$[\text{Mg}^{2+}](1.0 \times 10^{-5})^2 = 1.8 \times 10^{-11}$$

$$[\text{Mg}^{2+}] = \frac{1.8 \times 10^{-11}}{(1.0 \times 10^{-5})^2} = 0.18 \text{ M}$$

Thus, the $\text{Mg}(\text{OH})_2$ dissolves until $[\text{Mg}^{2+}] = 0.18 \text{ M}$. It is apparent that $\text{Mg}(\text{OH})_2$ is much more soluble in this solution.

CHEMISTRY AND LIFE

OCEAN ACIDIFICATION

Seawater is a weakly basic solution, with pH values typically between 8.0 and 8.3. This pH range is maintained through a carbonic acid buffer system similar to the one in blood (see Equation 17.10).

Because the pH of seawater is higher than in blood (7.35–7.45), however, the second dissociation of carbonic acid cannot be neglected and CO_3^{2-} becomes an important aqueous species.

The availability of carbonate ions plays an important role in shell formation for a number of marine organisms, including stony corals (► **FIGURE 17.18**). These organisms, which are referred to as marine *calcifiers* and play an important role in the food chains of nearly all oceanic ecosystems, depend on dissolved Ca^{2+} and CO_3^{2-} ions to form their shells and exoskeletons. The relatively low solubility-product constant of CaCO_3 ,

and the fact that the ocean contains saturated concentrations of Ca^{2+} and CO_3^{2-} mean that CaCO_3 is usually quite stable once formed. In fact, calcium carbonate skeletons of creatures that died millions of years ago are not uncommon in the fossil record.

Just as in our bodies, the carbonic acid buffer system can be perturbed by removing or adding $\text{CO}_2(g)$. The concentration of dissolved CO_2 in the ocean is sensitive to changes in atmospheric CO_2 levels. As discussed in Chapter 18, the atmospheric CO_2 concentration has risen by approximately 30% over the past three centuries to the present level of 386 ppm. Human activity has played a prominent role in this increase. Scientists estimate that one-third to one-half of the CO_2 emissions resulting from human activity have been absorbed by Earth's oceans. While this absorption helps miti-

gate the greenhouse gas effects of CO_2 , the extra CO_2 in the ocean produces carbonic acid, which lowers the pH. Because CO_3^{2-} is the conjugate base of the weak acid HCO_3^- , the carbonate ion readily combines with the hydrogen ion:

This consumption of carbonate ion shifts the dissolution equilibrium to the right, increasing the solubility of CaCO_3 . This can lead to partial dissolution of calcium carbonate shells and exoskeletons. If the amount of atmospheric CO_2 continues to increase at the present rate, scientists estimate that seawater pH will fall to 7.9 sometime over the next 50 years. While this change might sound small, it has dramatic ramifications for oceanic ecosystems.

RELATED EXERCISES: 17.97

▲ **FIGURE 17.18** Marine calcifiers. Many sea-dwelling organisms use CaCO_3 for their shells and exoskeletons. Examples include stony coral, crustaceans, some phytoplankton, and echinoderms, such as sea urchins and starfish.

If $[\text{OH}^-]$ were reduced further by making the solution even more acidic, the Mg^{2+} concentration would have to increase to maintain the equilibrium condition. Thus, a sample of $\text{Mg}(\text{OH})_2(s)$ dissolves completely if sufficient acid is added, as we saw in Figure 4.9 (page 128).

The solubility of almost any ionic compound is affected if the solution is made sufficiently acidic or basic. The effects are noticeable, however, only when one (or both) ions in the compound are at least moderately acidic or basic. The metal hydroxides, such as $\text{Mg}(\text{OH})_2$, are examples of compounds containing a strongly basic ion, the hydroxide ion.

In general, *the solubility of a compound containing a basic anion (that is, the anion of a weak acid) increases as the solution becomes more acidic.* As we have seen, the solubility of $\text{Mg}(\text{OH})_2$ greatly increases as the acidity of the solution increases. The solubility of PbF_2 increases as the solution becomes more acidic, too, because F^- is a weak base (it is the conjugate base of the weak acid HF). As a result, the solubility equilibrium of PbF_2 is shifted to the right as the concentration of F^- is reduced by protonation to form HF . Thus, the solution process can be understood in terms of two consecutive reactions:

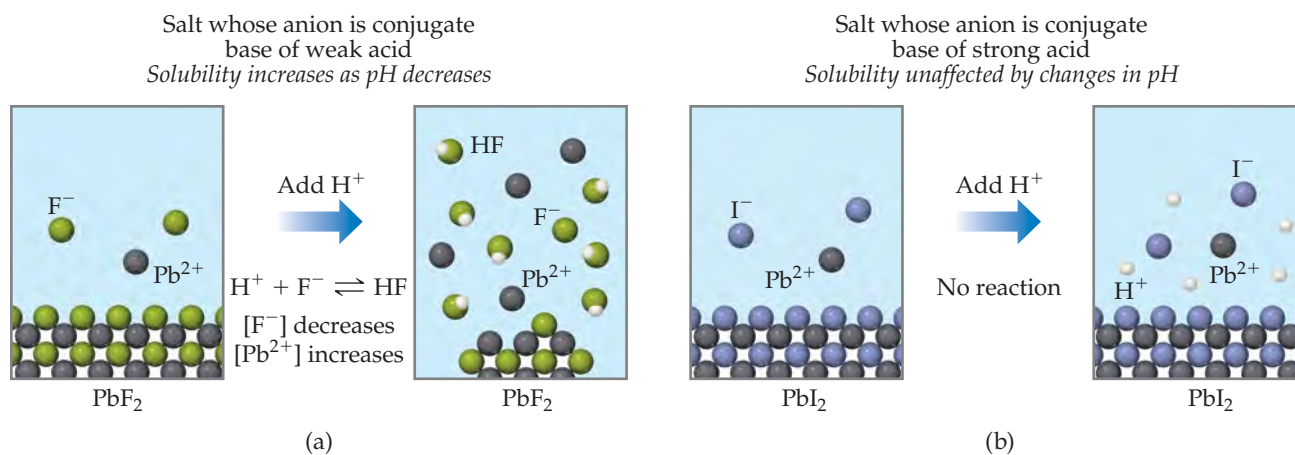

The equation for the overall process is

The processes responsible for the increase in solubility of PbF_2 in acidic solution are illustrated in **FIGURE 17.19(a)**.

Other salts that contain basic anions, such as CO_3^{2-} , PO_4^{3-} , CN^- , or S^{2-} , behave similarly. These examples illustrate a general rule: *The solubility of slightly soluble salts containing basic anions increases as $[\text{H}^+]$ increases (as pH is lowered).* The more basic the anion, the more the solubility is influenced by pH. The solubility of salts with anions of negligible basicity (the anions of strong acids), such as Cl^- , Br^- , I^- and NO_3^- , is unaffected by pH changes, as shown in Figure 17.19(b).

▲ FIGURE 17.19 Response of two ionic compounds to addition of a strong acid.

(a) The solubility of PbF_2 increases on addition of acid. (b) The solubility of PbI_2 is not affected by addition of acid. The water molecules and the anion of the strong acid have been omitted for clarity.

SAMPLE EXERCISE 17.13 Predicting the Effect of Acid on Solubility

Which of these substances are more soluble in acidic solution than in basic solution: (a) $\text{Ni}(\text{OH})_2(\text{s})$, (b) $\text{CaCO}_3(\text{s})$, (c) $\text{BaF}_2(\text{s})$, (d) $\text{AgCl}(\text{s})$?

SOLUTION

Analyze The problem lists four sparingly soluble salts, and we are asked to determine which are more soluble at low pH than at high pH.

Plan Ionic compounds that dissociate to produce a basic anion are more soluble in acid solution.

Solve

(a) $\text{Ni}(\text{OH})_2(\text{s})$ is more soluble in acidic solution because of the basicity of OH^- ; the H^+ reacts with the OH^- ion, forming water:

(b) Similarly, $\text{CaCO}_3(\text{s})$ dissolves in acid solutions because CO_3^{2-} is a basic anion:

The reaction between CO_3^{2-} and H^+ occurs in steps, with HCO_3^- forming first and H_2CO_3 forming in appreciable amounts only when $[\text{H}^+]$ is sufficiently high.

(c) The solubility of BaF_2 is enhanced by lowering the pH because F^- is a basic anion:

(d) The solubility of AgCl is unaffected by changes in pH because Cl^- is the anion of a strong acid and therefore has negligible basicity.

PRACTICE EXERCISE

Write the net ionic equation for the reaction between an acid and (a) CuS , (b) $\text{Cu}(\text{N}_3)_2$.

Answers: (a) $\text{CuS}(\text{s}) + \text{H}^{+}(\text{aq}) \rightleftharpoons \text{Cu}^{2+}(\text{aq}) + \text{HS}^{-}(\text{aq})$

(b) $\text{Cu}(\text{N}_3)_2(\text{s}) + 2 \text{H}^{+}(\text{aq}) \rightleftharpoons \text{Cu}^{2+}(\text{aq}) + 2 \text{HN}_3(\text{aq})$

CHEMISTRY AND LIFE**TOOTH DECAY AND FLUORIDATION**

Tooth enamel consists mainly of the mineral hydroxyapatite, $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$, the hardest substance in the body. Tooth cavities form when acids dissolve tooth enamel:

The Ca^{2+} and HPO_4^{2-} ions diffuse out of the enamel and are washed away by saliva. The acids that attack the hydroxyapatite are formed by the action of bacteria on sugars and other carbohydrates present in the plaque adhering to the teeth.

Fluoride ion, which is added to municipal water systems and toothpastes, can react with hydroxyapatite to form fluoroapatite,

$\text{Ca}_{10}(\text{PO}_4)_6\text{F}_2$. This mineral, in which F^- has replaced OH^- , is much more resistant to attack by acids because the fluoride ion is a much weaker Brønsted–Lowry base than the hydroxide ion.

The usual concentration of F^- in municipal water systems is 1 mg/L (1 ppm). The compound added may be NaF or Na_2SiF_6 . The silicon–fluorine anion reacts with water to release fluoride ions:

About 80% of all toothpastes now sold in the United States contain fluoride compounds, usually at the level of 0.1% fluoride by mass. The most common compounds in toothpastes are sodium fluoride (NaF), sodium monofluorophosphate ($\text{Na}_2\text{PO}_3\text{F}$), and stannous fluoride (SnF_2).

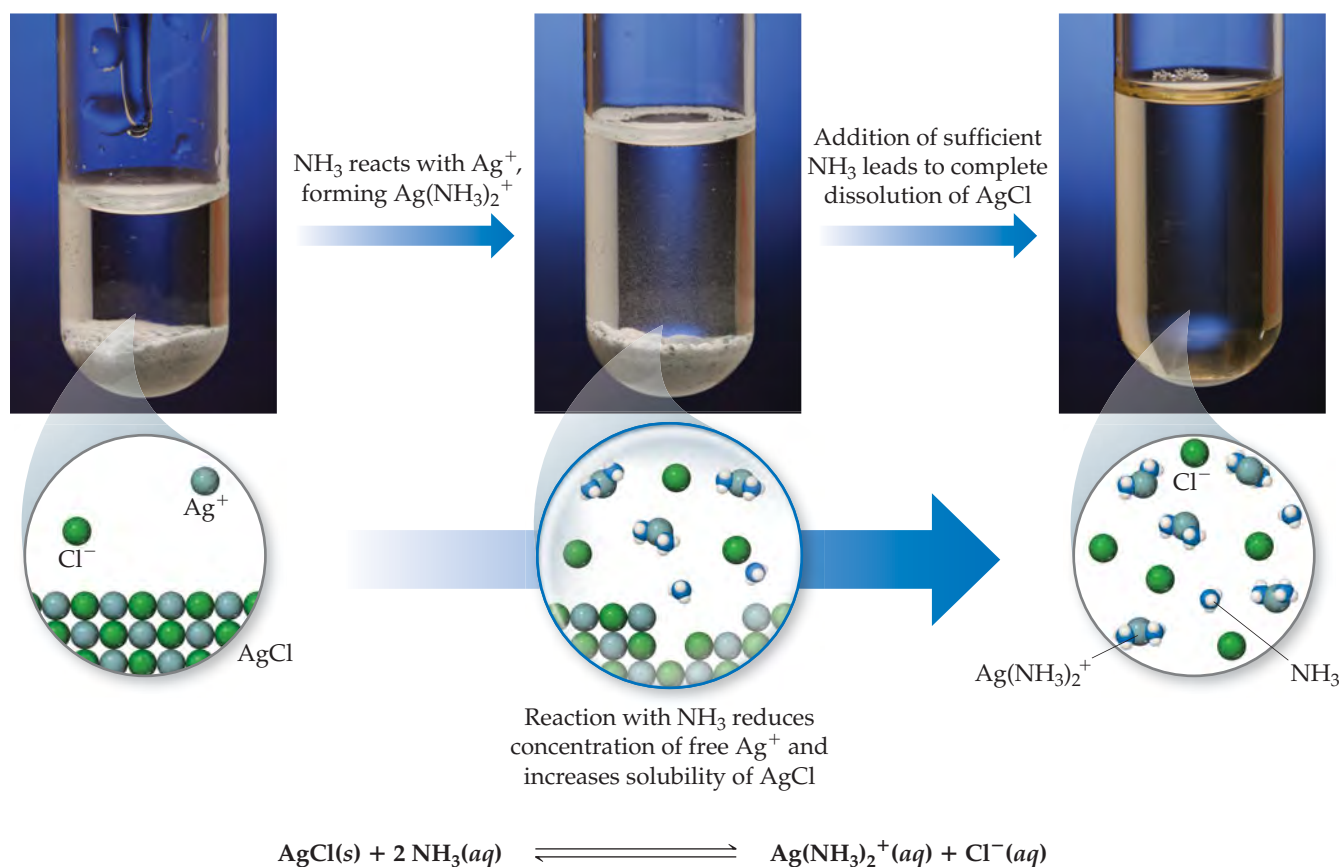

RELATED EXERCISES: 17.98 and 17.116

Formation of Complex Ions

A characteristic property of metal ions is their ability to act as Lewis acids toward water molecules, which act as Lewis bases. ∞ (Section 16.11) Lewis bases other than water can also interact with metal ions, particularly transition-metal ions. Such interactions can dramatically affect the solubility of a metal salt. For example, AgCl ($K_{sp} = 1.8 \times 10^{-10}$) dissolves in the presence of aqueous ammonia because Ag^+ interacts with the Lewis base NH_3 , as shown in \blacktriangledown FIGURE 17.20. This process can be viewed as the sum of two reactions:

The presence of NH_3 drives the reaction, the dissolution of AgCl , to the right as $\text{Ag}^+(aq)$ is consumed to form $\text{Ag}(\text{NH}_3)_2^+$.

\blacktriangle FIGURE 17.20 Using concentrated $\text{NH}_3(aq)$ to dissolve $\text{AgCl}(s)$, which has very low solubility in water.

For a Lewis base such as NH_3 to increase the solubility of a metal salt, the base must be able to interact more strongly with the metal ion than water does. In other words, the NH_3 must displace solvating H_2O molecules ∞ (Sections 13.1 and 16.11) in order to form $\text{Ag}(\text{NH}_3)_2^+$:

TABLE 17.1 • Formation Constants for Some Metal Complex Ions in Water at 25 °C

Complex Ion	K_f	Equilibrium Equation
$\text{Ag}(\text{NH}_3)_2^+$	1.7×10^7	$\text{Ag}^+(aq) + 2 \text{NH}_3(aq) \rightleftharpoons \text{Ag}(\text{NH}_3)_2^+(aq)$
$\text{Ag}(\text{CN})_2^-$	1×10^{21}	$\text{Ag}^+(aq) + 2 \text{CN}^-(aq) \rightleftharpoons \text{Ag}(\text{CN})_2^-(aq)$
$\text{Ag}(\text{S}_2\text{O}_3)_2^{3-}$	2.9×10^{13}	$\text{Ag}^+(aq) + 2 \text{S}_2\text{O}_3^{2-}(aq) \rightleftharpoons \text{Ag}(\text{S}_2\text{O}_3)_2^{3-}(aq)$
CdBr_4^{2-}	5×10^3	$\text{Cd}^{2+}(aq) + 4 \text{Br}^-(aq) \rightleftharpoons \text{CdBr}_4^{2-}(aq)$
$\text{Cr}(\text{OH})_4^-$	8×10^{29}	$\text{Cr}^{3+}(aq) + 4 \text{OH}^-(aq) \rightleftharpoons \text{Cr}(\text{OH})_4^-(aq)$
$\text{Co}(\text{SCN})_4^{2-}$	1×10^3	$\text{Co}^{2+}(aq) + 4 \text{SCN}^-(aq) \rightleftharpoons \text{Co}(\text{SCN})_4^{2-}(aq)$
$\text{Cu}(\text{NH}_3)_4^{2+}$	5×10^{12}	$\text{Cu}^{2+}(aq) + 4 \text{NH}_3(aq) \rightleftharpoons \text{Cu}(\text{NH}_3)_4^{2+}(aq)$
$\text{Cu}(\text{CN})_4^{2-}$	1×10^{25}	$\text{Cu}^{2+}(aq) + 4 \text{CN}^-(aq) \rightleftharpoons \text{Cu}(\text{CN})_4^{2-}(aq)$
$\text{Ni}(\text{NH}_3)_6^{2+}$	1.2×10^9	$\text{Ni}^{2+}(aq) + 6 \text{NH}_3(aq) \rightleftharpoons \text{Ni}(\text{NH}_3)_6^{2+}(aq)$
$\text{Fe}(\text{CN})_6^{4-}$	1×10^{35}	$\text{Fe}^{2+}(aq) + 6 \text{CN}^-(aq) \rightleftharpoons \text{Fe}(\text{CN})_6^{4-}(aq)$
$\text{Fe}(\text{CN})_6^{3-}$	1×10^{42}	$\text{Fe}^{3+}(aq) + 6 \text{CN}^-(aq) \rightleftharpoons \text{Fe}(\text{CN})_6^{3-}(aq)$

An assembly of a metal ion and the Lewis bases bonded to it, such as $\text{Ag}(\text{NH}_3)_2^+$, is called a **complex ion**. The stability of a complex ion in aqueous solution can be judged by the size of the equilibrium constant for its formation from the hydrated metal ion. For example, the equilibrium constant for Equation 17.24 is

$$K_f = \frac{[\text{Ag}(\text{NH}_3)_2^+]}{[\text{Ag}^+][\text{NH}_3]^2} = 1.7 \times 10^7 \quad [17.25]$$

Note that the equilibrium constant for this kind of reaction is called a **formation constant**, K_f . The formation constants for several complex ions are listed in **TABLE 17.1**.

SAMPLE EXERCISE 17.14 Evaluating an Equilibrium Involving a Complex Ion

Calculate the concentration of Ag^+ present in solution at equilibrium when concentrated ammonia is added to a 0.010 M solution of AgNO_3 to give an equilibrium concentration of $[\text{NH}_3] = 0.20 \text{ M}$. Neglect the small volume change that occurs when NH_3 is added.

SOLUTION

Analyze Addition of $\text{NH}_3(aq)$ to $\text{Ag}^+(aq)$ forms $\text{Ag}(\text{NH}_3)_2^+$, as shown in Equation 17.22. We are asked to determine what concentration of $\text{Ag}^+(aq)$ remains uncombined when the NH_3 concentration is brought to 0.20 M in a solution originally 0.010 M in AgNO_3 .

Plan We assume that the AgNO_3 is completely dissociated, giving 0.010 M Ag^+ . Because K_f for the formation of $\text{Ag}(\text{NH}_3)_2^+$ is quite large, we assume that essentially all the Ag^+ is converted to $\text{Ag}(\text{NH}_3)_2^+$ and approach the problem as though we are concerned with the dissociation of $\text{Ag}(\text{NH}_3)_2^+$ rather than its formation. To facilitate this approach, we need to reverse Equation 17.22 and make the corresponding change to the equilibrium constant:

Solve If $[\text{Ag}^+]$ is 0.010 M initially, $[\text{Ag}(\text{NH}_3)_2^+]$ will be 0.010 M following addition of the NH_3 . We construct a table to solve this equilibrium problem. Note that the NH_3 concentration given in the problem is an equilibrium concentration rather than an initial concentration.

	$\text{Ag}(\text{NH}_3)_2^+(aq)$	\rightleftharpoons	$\text{Ag}^+(aq)$	+	$2 \text{NH}_3(aq)$
Initial	0.010 M		0 M		
Change	$-x \text{ M}$		$+x \text{ M}$		
Equilibrium	$0.010 - x \text{ M}$		$x \text{ M}$		0.20 M

Because $[\text{Ag}^+]$ is very small, we can ignore x , so that $0.010 - x \approx 0.010 \text{ M}$. Substituting these values into the equilibrium-constant expression for the dissociation of $\text{Ag}(\text{NH}_3)_2^+$, we obtain

$$\frac{[\text{Ag}^+][\text{NH}_3]^2}{[\text{Ag}(\text{NH}_3)_2^+]} = \frac{(x)(0.20)^2}{0.010} = 5.9 \times 10^{-8}$$

$$x = 1.5 \times 10^{-8} \text{ M} = [\text{Ag}^+]$$

Formation of the $\text{Ag}(\text{NH}_3)_2^+$ complex drastically reduces the concentration of free Ag^+ ion in solution.

PRACTICE EXERCISE

Calculate $[\text{Cr}^{3+}]$ in equilibrium with $\text{Cr}(\text{OH})_4^-$ when 0.010 mol of $\text{Cr}(\text{NO}_3)_3$ is dissolved in 1 L of solution buffered at pH 10.0.

Answer: $1 \times 10^{-16} \text{ M}$

The general rule is that the solubility of metal salts increases in the presence of suitable Lewis bases, such as NH_3 , CN^- , or OH^- , provided the metal forms a complex with the base. The ability of metal ions to form complexes is an extremely important aspect of their chemistry.

Amphoterism

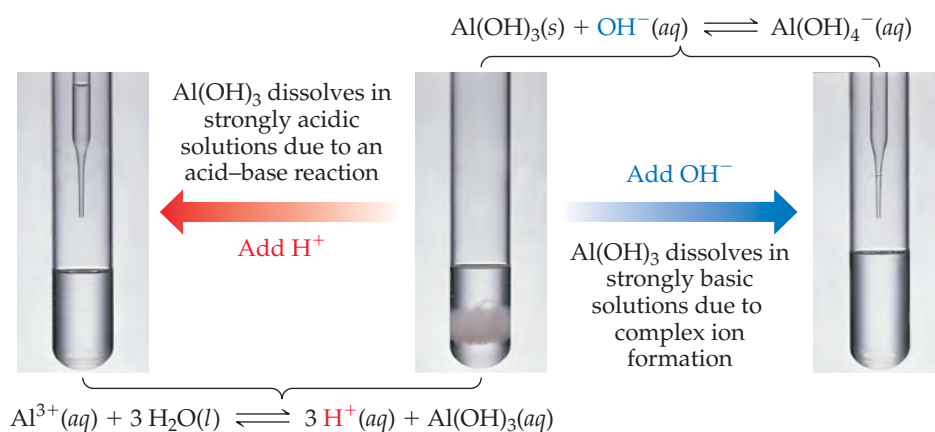

Some metal oxides and hydroxides that are relatively insoluble in water dissolve in strongly acidic and strongly basic solutions. These substances, called **amphoteric oxides** and **amphoteric hydroxides**,* are soluble in strong acids and bases because they themselves are capable of behaving as either an acid or base. Examples of amphoteric substances include the oxides and hydroxides of Al^{3+} , Cr^{3+} , Zn^{2+} , and Sn^{2+} .

Like other metal oxides and hydroxides, amphoteric species dissolve in acidic solutions because their anions, O^{2-} or OH^- , react with acids. What makes amphoteric oxides and hydroxides special, though, is that they also dissolve in strongly basic solutions. This behavior results from the formation of complex anions containing several (typically four) hydroxides bound to the metal ion (▼ FIGURE 17.21):

The extent to which an insoluble metal hydroxide reacts with either acid or base varies with the particular metal ion involved. Many metal hydroxides—such as $\text{Ca}(\text{OH})_2$, $\text{Fe}(\text{OH})_2$, and $\text{Fe}(\text{OH})_3$ —are capable of dissolving in acidic solution but do not react with excess base. These hydroxides are not amphoteric.

The purification of aluminum ore in the manufacture of aluminum metal provides an interesting application of amphoterism. As we have seen, $\text{Al}(\text{OH})_3$ is amphoteric,

◀ FIGURE 17.21 Amphoterism. Some metal oxides and hydroxides, such as $\text{Al}(\text{OH})_3$, are amphoteric, which means they dissolve in both strongly acidic and strongly basic solutions.

*Notice that the term *amphoteric* is applied to the behavior of insoluble oxides and hydroxides that dissolve in acidic or basic solutions. The similar term *amphiprotic* (Section 16.2) relates more generally to any molecule or ion that can either gain or lose a proton.

whereas $\text{Fe}(\text{OH})_3$ is not. Aluminum occurs in large quantities as the ore *bauxite*, which is essentially hydrated Al_2O_3 contaminated with Fe_2O_3 . When bauxite is added to a strongly basic solution, the Al_2O_3 dissolves because the aluminum forms complex ions, such as $\text{Al}(\text{OH})_4^-$. The Fe_2O_3 impurity, however, is not amphoteric and remains as a solid. The solution is filtered, getting rid of the iron impurity. Aluminum hydroxide is then precipitated by addition of acid. The purified hydroxide receives further treatment and eventually yields aluminum metal.

GIVE IT SOME THOUGHT

What is the difference between an amphoteric substance and an amphiprotic substance?

17.6 | PRECIPITATION AND SEPARATION OF IONS

Equilibrium can be achieved starting with the substances on either side of a chemical equation. For example, the equilibrium that exists between $\text{BaSO}_4(s)$, $\text{Ba}^{2+}(aq)$, and $\text{SO}_4^{2-}(aq)$ (Equation 17.15), can be achieved either by starting with $\text{BaSO}_4(s)$ or by starting with solutions containing Ba^{2+} and SO_4^{2-} . If we mix, say, a BaCl_2 aqueous solution and a Na_2SO_4 aqueous solution, BaSO_4 precipitates if the product of the initial ion concentrations, $Q = [\text{Ba}^{2+}][\text{SO}_4^{2-}]$, is greater than K_{sp} .

The use of the reaction quotient Q to determine the direction in which a reaction must proceed to reach equilibrium was discussed in Section 15.6. The possible relationships between Q and K_{sp} are as follows:

- If $Q > K_{sp}$, precipitation occurs, reducing ion concentrations until $Q = K_{sp}$.
- If $Q = K_{sp}$, equilibrium exists (saturated solution).
- If $Q < K_{sp}$, solid dissolves, increasing ion concentrations until $Q = K_{sp}$.

SAMPLE EXERCISE 17.15 Predicting Whether a Precipitate Forms

Does a precipitate form when 0.10 L of $8.0 \times 10^{-3} M \text{Pb}(\text{NO}_3)_2$ is added to 0.40 L of $5.0 \times 10^{-3} M \text{Na}_2\text{SO}_4$?

SOLUTION

Analyze The problem asks us to determine whether a precipitate forms when two salt solutions are combined.

Plan We should determine the concentrations of all ions just after the solutions are mixed and compare the value of Q with K_{sp} for any potentially insoluble product. The possible metathesis products are PbSO_4 and NaNO_3 . Like all sodium salts NaNO_3 is soluble, but PbSO_4 has a K_{sp} of 6.3×10^{-7} (Appendix D) and will precipitate if the Pb^{2+} and SO_4^{2-} concentrations are high enough for Q to exceed K_{sp} .

Solve When the two solutions are mixed, the volume is $0.10 \text{ L} + 0.40 \text{ L} = 0.50 \text{ L}$. The number of moles of Pb^{2+} in 0.10 L of $8.0 \times 10^{-3} M \text{Pb}(\text{NO}_3)_2$ is

$$(0.10 \text{ L}) \left(\frac{8.0 \times 10^{-3} \text{ mol}}{\text{L}} \right) = 8.0 \times 10^{-4} \text{ mol}$$

The concentration of Pb^{2+} in the 0.50-L mixture is therefore

$$[\text{Pb}^{2+}] = \frac{8.0 \times 10^{-4} \text{ mol}}{0.50 \text{ L}} = 1.6 \times 10^{-3} M$$

The number of moles of SO_4^{2-} in 0.40 L of $5.0 \times 10^{-3} M \text{Na}_2\text{SO}_4$ is

$$(0.40 \text{ L}) \left(\frac{5.0 \times 10^{-3} \text{ mol}}{\text{L}} \right) = 2.0 \times 10^{-3} \text{ mol}$$

Therefore

$$[\text{SO}_4^{2-}] = \frac{2.0 \times 10^{-3} \text{ mol}}{0.50 \text{ L}} = 4.0 \times 10^{-3} M$$

and

$$Q = [\text{Pb}^{2+}][\text{SO}_4^{2-}] = (1.6 \times 10^{-3})(4.0 \times 10^{-3}) = 6.4 \times 10^{-6}$$

Because $Q > K_{sp}$, PbSO_4 precipitates.

PRACTICE EXERCISE

Does a precipitate form when 0.050 L of $2.0 \times 10^{-2} M \text{NaF}$ is mixed with 0.010 L of $1.0 \times 10^{-2} M \text{Ca}(\text{NO}_3)_2$?

Answer: Yes, CaF_2 precipitates because $Q = 4.6 \times 10^{-8}$ is larger than $K_{sp} = 3.9 \times 10^{-11}$

Selective Precipitation of Ions

Ions can be separated from each other based on the solubilities of their salts. Consider a solution containing both Ag^+ and Cu^{2+} . If HCl is added to the solution, AgCl ($K_{sp} = 1.8 \times 10^{-10}$) precipitates, while Cu^{2+} remains in solution because CuCl_2 is soluble. Separation of ions in an aqueous solution by using a reagent that forms a precipitate with one or more (but not all) of the ions is called *selective precipitation*.

SAMPLE EXERCISE 17.16 Calculating Ion Concentrations for Precipitation

A solution contains $1.0 \times 10^{-2} M \text{Ag}^+$ and $2.0 \times 10^{-2} M \text{Pb}^{2+}$. When Cl^- is added, both AgCl ($K_{sp} = 1.8 \times 10^{-10}$) and PbCl_2 ($K_{sp} = 1.7 \times 10^{-5}$) can precipitate. What concentration of Cl^- is necessary to begin the precipitation of each salt? Which salt precipitates first?

SOLUTION

Analyze We are asked to determine the concentration of Cl^- necessary to begin the precipitation from a solution containing Ag^+ and Pb^{2+} ions, and to predict which metal chloride will begin to precipitate first.

Plan We are given K_{sp} values for the two precipitates. Using these and the metal ion concentrations, we can calculate what Cl^- concentration is necessary to precipitate each salt. The salt requiring the lower Cl^- ion concentration precipitates first.

Solve For AgCl we have $K_{sp} = [\text{Ag}^+][\text{Cl}^-] = 1.8 \times 10^{-10}$

Because $[\text{Ag}^+] = 1.0 \times 10^{-2} M$, the greatest concentration of Cl^- that can be present without causing precipitation of AgCl can be calculated from the K_{sp} expression:

$$K_{sp} = (1.0 \times 10^{-2})[\text{Cl}^-] = 1.8 \times 10^{-10}$$

$$[\text{Cl}^-] = \frac{1.8 \times 10^{-10}}{1.0 \times 10^{-2}} = 1.8 \times 10^{-8} M$$

Any Cl^- in excess of this very small concentration will cause AgCl to precipitate from solution. Proceeding similarly for PbCl_2 , we have

$$K_{sp} = [\text{Pb}^{2+}][\text{Cl}^-]^2 = 1.7 \times 10^{-5}$$

$$[2.0 \times 10^{-2}][\text{Cl}^-]^2 = 1.7 \times 10^{-5}$$

$$[\text{Cl}^-]^2 = \frac{1.7 \times 10^{-5}}{2.0 \times 10^{-2}} = 8.5 \times 10^{-4}$$

$$[\text{Cl}^-] = \sqrt{8.5 \times 10^{-4}} = 2.9 \times 10^{-2} M$$

Thus, a concentration of Cl^- in excess of $2.9 \times 10^{-2} M$ causes PbCl_2 to precipitate.

Comparing the Cl^- concentration required to precipitate each salt, we see that as Cl^- is added, AgCl precipitates first because it requires a much smaller concentration of Cl^- . Thus, Ag^+ can be separated from Pb^{2+} by slowly adding Cl^- so that the chloride ion concentration remains between $1.8 \times 10^{-8} M$ and $2.9 \times 10^{-2} M$.

Comment Precipitation of AgCl will keep the Cl^- concentration low until the number of moles of Cl^- added exceeds the number of moles of Ag^+ in the solution. Once past this point, $[\text{Cl}^-]$ rises sharply and PbCl_2 will soon begin to precipitate.

PRACTICE EXERCISE

A solution consists of $0.050 M \text{Mg}^{2+}$ and Cu^{2+} . Which ion precipitates first as OH^- is added? What concentration of OH^- is necessary to begin the precipitation of each cation? [$K_{sp} = 1.8 \times 10^{-11}$ for $\text{Mg}(\text{OH})_2$, and $K_{sp} = 4.8 \times 10^{-20}$ for $\text{Cu}(\text{OH})_2$.]

Answer: $\text{Cu}(\text{OH})_2$ precipitates first, beginning when $[\text{OH}^-] > 1.5 \times 10^{-9} M$. $\text{Mg}(\text{OH})_2$ begins to precipitate when $[\text{OH}^-] > 1.9 \times 10^{-5} M$.

GO FIGURE

What would happen if the pH were raised to 8 first and then H₂S were added?

▶ FIGURE 17.22
Selective precipitation. In this example Cu²⁺ ions are separated from Zn²⁺ ions.

Sulfide ion is often used to separate metal ions because the solubilities of sulfide salts span a wide range and depend greatly on solution pH. For example, Cu²⁺ and Zn²⁺ can be separated by bubbling H₂S gas through an acidified solution containing these two cations. Because CuS ($K_{sp} = 6 \times 10^{-37}$) is less soluble than ZnS ($K_{sp} = 2 \times 10^{-25}$), CuS precipitates from an acidified solution pH \approx 1 while ZnS does not (▲ FIGURE 17.22):

The CuS can be separated from the Zn²⁺ solution by filtration. The CuS can then be dissolved by raising the concentration of H⁺ even further, shifting the equilibrium of Equation 17.27 to the left.

17.7 QUALITATIVE ANALYSIS FOR METALLIC ELEMENTS

In this final section, we look at how solubility equilibria and complex-ion formation can be used to detect the presence of particular metal ions in solution. Before the development of modern analytical instrumentation, it was necessary to analyze mixtures of metals in a sample by what were called *wet chemical methods*. For example, an ore sample that might contain several metallic elements was dissolved in a concentrated acid solution that was then tested in a systematic way for the presence of various metal ions.

Qualitative analysis determines only the presence or absence of a particular metal ion, whereas **quantitative analysis** determines how much of a given substance is present. Even though wet methods of qualitative analysis have become less important in the chemical industry, they are frequently used in general chemistry laboratory programs to

illustrate equilibria, to teach the properties of common metal ions in solution, and to develop laboratory skills. Typically, such analyses proceed in three stages: (1) The ions are separated into broad groups on the basis of solubility properties. (2) The ions in each group are separated by selectively dissolving members in the group. (3) The ions are identified by means of specific tests.

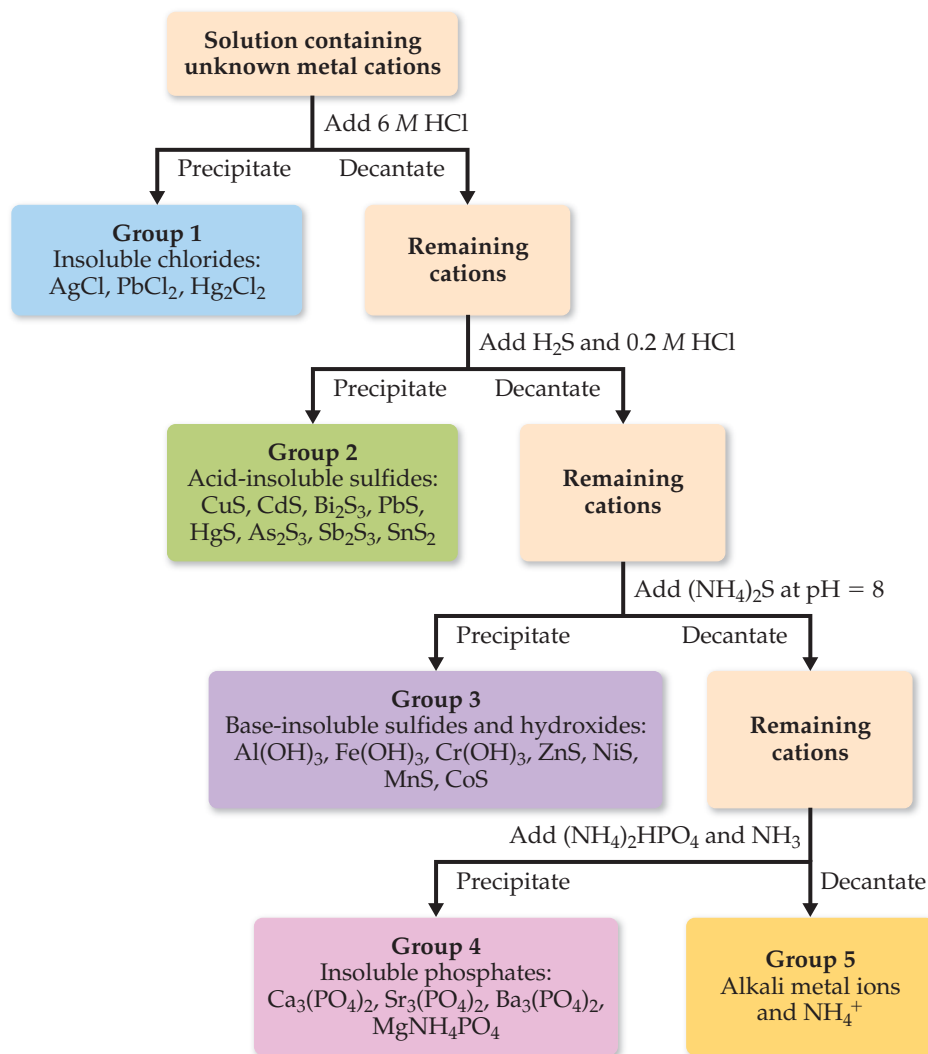

A scheme in general use divides the common cations into five groups (▼ FIGURE 17.23). The order in which reagents are added is important in this scheme. The most selective separations—those that involve the smallest number of ions—are carried out first. The reactions used must proceed so far toward completion that any concentration of cations remaining in the solution is too small to interfere with subsequent tests.

Let's look at each of these five groups of cations, briefly examining the logic used in this qualitative analysis scheme.

Group 1. Insoluble chlorides: Of the common metal ions, only Ag^+ , Hg_2^{2+} , and Pb^{2+} form insoluble chlorides. When HCl is added to a mixture of cations, therefore, only AgCl , Hg_2Cl_2 , and PbCl_2 precipitate, leaving the other cations in solution. The absence of a precipitate indicates that the starting solution contains no Ag^+ , Hg_2^{2+} , or Pb^{2+} .

GO FIGURE

If a solution contained a mixture of Cu^{2+} and Zn^{2+} ions, would this separation scheme work? After which step would the first precipitate be observed?

◀ FIGURE 17.23 Qualitative analysis. A flowchart showing a common scheme for identifying cations.

Group 2. Acid-insoluble sulfides: After any insoluble chlorides have been removed, the remaining solution, now acidic, is treated with H_2S . Only the most insoluble metal sulfides— CuS , Bi_2S_3 , CdS , PbS , HgS , As_2S_3 , Sb_2S_3 , and SnS_2 —precipitate. (Note the very small values of K_{sp} for some of these sulfides in Appendix D.) Those metal ions whose sulfides are somewhat more soluble—for example, ZnS or NiS —remain in solution.

Group 3. Base-insoluble sulfides and hydroxides: After the solution is filtered to remove any acid-insoluble sulfides, it is made slightly basic, and $(\text{NH}_4)_2\text{S}$ is added. In basic solutions the concentration of S^{2-} is higher than in acidic solutions. Thus, the ion products for many of the more soluble sulfides are made to exceed their K_{sp} values and precipitation occurs. The metal ions precipitated at this stage are Al^{3+} , Cr^{3+} , Fe^{3+} , Zn^{2+} , Ni^{2+} , Co^{2+} , and Mn^{2+} (The Al^{3+} , Fe^{3+} , and Cr^{3+} ions do not form insoluble sulfides; instead they precipitate as insoluble hydroxides, as Figure 17.23 shows.)

Group 4. Insoluble phosphates: At this point the solution contains only metal ions from groups 1A and 2A of the periodic table. Adding $(\text{NH}_4)_2\text{HPO}_4$ to a basic solution precipitates the group 2A elements Mg^{2+} , Ca^{2+} , Sr^{2+} , and Ba^{2+} because these metals form insoluble phosphates.

Group 5. The alkali metal ions and NH_4^+ : The ions that remain after removing the insoluble phosphates are tested for individually. A flame test can be used to determine the presence of K^+ , for example, because the flame turns a characteristic violet color if K^+ is present.

GIVE IT SOME THOUGHT

If a precipitate forms when HCl is added to an aqueous solution, what conclusions can you draw about the contents of the solution?

SAMPLE INTEGRATIVE EXERCISE Putting Concepts Together

A sample of 1.25 L of HCl gas at 21°C and 0.950 atm is bubbled through 0.500 L of 0.150 M NH_3 solution. Calculate the pH of the resulting solution assuming that all the HCl dissolves and that the volume of the solution remains 0.500 L.

SOLUTION

The number of moles of HCl gas is calculated from the ideal-gas law,

$$n = \frac{PV}{RT} = \frac{(0.950 \text{ atm})(1.25 \text{ L})}{(0.0821 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(294 \text{ K})} = 0.0492 \text{ mol HCl}$$

The number of moles of NH_3 in the solution is given by the product of the volume of the solution and its concentration,

$$\text{Moles NH}_3 = (0.500 \text{ L})(0.150 \text{ mol NH}_3/\text{L}) = 0.0750 \text{ mol NH}_3$$

The acid HCl and base NH_3 react, transferring a proton from HCl to NH_3 , producing NH_4^+ and Cl^- ions,

To determine the pH of the solution, we first calculate the amount of each reactant and each product present at the completion of the reaction,

Before addition	0	0.0750 mol	0	0
Addition	0.0492 mol			
After addition	0	0.0258 mol	0.0492 mol	0.0492 mol

Thus, the reaction produces a solution containing a mixture of NH_3 , NH_4^+ , and Cl^- . The NH_3 is a weak base ($K_b = 1.8 \times 10^{-5}$), NH_4^+ is its conjugate acid, and Cl^- is neither acidic nor basic. Consequently, the pH depends on $[\text{NH}_3]$ and $[\text{NH}_4^+]$,

$$[\text{NH}_3] = \frac{0.0258 \text{ mol NH}_3}{0.500 \text{ L soln}} = 0.0516 \text{ M}$$

$$[\text{NH}_4^+] = \frac{0.0492 \text{ mol NH}_4^+}{0.500 \text{ L soln}} = 0.0984 \text{ M}$$

We can calculate the pH using either K_b for NH_3 or K_a for NH_4^+ . Using the K_b expression, we have

Initial	0.0516 M	—	0.0984 M	0
Change	$-x$ M	—	$+x$ M	$+x$ M
Equilibrium	$(0.0516 - x)$ M	—	$(0.0984 + x)$ M	x M

$$K_b = \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]} = \frac{(0.0984 + x)(x)}{(0.0516 - x)} \approx \frac{(0.0984)x}{0.0516} = 1.8 \times 10^{-5}$$

$$x = [\text{OH}^-] = \frac{(0.0516)(1.8 \times 10^{-5})}{0.0984} = 9.4 \times 10^{-6} \text{ M}$$

Hence, $\text{pOH} = -\log(9.4 \times 10^{-6}) = 5.03$ and $\text{pH} = 14.00 - \text{pOH} = 14.00 - 5.03 = 8.97$.

CHAPTER SUMMARY AND KEY TERMS

SECTION 17.1 In this chapter we have considered several types of important equilibria that occur in aqueous solution. Our primary emphasis has been on acid–base equilibria in solutions containing two or more solutes and on solubility equilibria. The dissociation of a weak acid or weak base is repressed by the presence of a strong electrolyte that provides an ion common to the equilibrium. This phenomenon is called the **common-ion effect**.

SECTION 17.2 A particularly important type of acid–base mixture is that of a weak conjugate acid–base pair. Such mixtures function as **buffered solutions (buffers)**. Addition of small amounts of a strong acid or a strong base to a buffered solution causes only small changes in pH because the buffer reacts with the added acid or base. (Strong acid–strong base, strong acid–weak base, and weak acid–strong base reactions proceed essentially to completion.) Buffered solutions are usually prepared from a weak acid and a salt of that acid or from a weak base and a salt of that base. Two important characteristics of a buffered solution are its **buffer capacity** and its **pH range**. The optimal pH of a buffer is equal to $\text{p}K_a$ (or $\text{p}K_b$) of the acid (or base) used to prepare the buffer. The relationship between pH, $\text{p}K_a$, and the concentrations of an acid and its conjugate base can be expressed by the **Henderson–Hasselbalch equation**.

SECTION 17.3 The plot of the pH of an acid (or base) as a function of the volume of added base (or acid) is called a **pH titration curve**. The titration curve of a strong acid–strong base titration exhibits a large change in pH in the immediate vicinity of the equivalence point; at the equivalence point for such a titration $\text{pH} = 7$. For strong acid–weak base or weak acid–strong base titrations, the pH change in the vicinity of the equivalence point is not as large. Furthermore, the pH at the equivalence point is not 7 in either of these cases. Rather, it is the pH of the salt solution that results from the neutralization reaction. For this reason it is important to choose an indicator whose color change is near the pH at the equivalence point for titrations involving either weak acids or weak bases. It is possible to calculate the pH at any point of the titration curve by first considering the effects of the acid–base reaction on solution concentrations and then examining equilibria involving the remaining solute species.

SECTION 17.4 The equilibrium between a solid compound and its ions in solution provides an example of heterogeneous equilibrium.

The **solubility-product constant** (or simply the **solubility product**), K_{sp} , is an equilibrium constant that expresses quantitatively the extent to which the compound dissolves. The K_{sp} can be used to calculate the solubility of an ionic compound, and the solubility can be used to calculate K_{sp} .

SECTION 17.5 Several experimental factors, including temperature, affect the solubilities of ionic compounds in water. The solubility of a slightly soluble ionic compound is decreased by the presence of a second solute that furnishes a common ion (the common-ion effect). The solubility of compounds containing basic anions increases as the solution is made more acidic (as pH decreases). Salts with anions of negligible basicity (the anions of strong acids) are unaffected by pH changes.

The solubility of metal salts is also affected by the presence of certain Lewis bases that react with metal ions to form stable **complex ions**. Complex-ion formation in aqueous solution involves the displacement by Lewis bases (such as NH_3 and CN^-) of water molecules attached to the metal ion. The extent to which such complex formation occurs is expressed quantitatively by the **formation constant** for the complex ion. **Amphoteric oxides** and **hydroxides** are those that are only slightly soluble in water but dissolve on addition of either acid or base.

SECTION 17.6 Comparison of the ion product, Q , with the value of K_{sp} can be used to judge whether a precipitate will form when solutions are mixed or whether a slightly soluble salt will dissolve under various conditions. Precipitates form when $Q > K_{sp}$. If two salts have sufficiently different solubilities, selective precipitation can be used to precipitate one ion while leaving the other in solution, effectively separating the two ions.

SECTION 17.7 Metallic elements vary a great deal in the solubilities of their salts, in their acid–base behavior, and in their tendencies to form complex ions. These differences can be used to separate and detect the presence of metal ions in mixtures. **Qualitative analysis** determines the presence or absence of species in a sample, whereas **quantitative analysis** determines how much of each species is present. The qualitative analysis of metal ions in solution can be carried out by separating the ions into groups on the basis of precipitation reactions and then analyzing each group for individual metal ions.

KEY SKILLS

- Describe the common-ion effect. (Section 17.1)
- Explain how a buffer functions. (Section 17.2)
- Calculate the pH of a buffered solution. (Section 17.2)
- Calculate the pH of a buffer after the addition of small amounts of a strong acid or a strong base. (Section 17.2)
- Calculate the pH at any point in a strong acid–strong base titration. (Section 17.3)
- Calculate the pH at any point in a weak acid–strong base or weak base–strong acid titration. (Section 17.3)
- Understand the differences between the titration curves for a strong acid–strong base titration and those when either the acid or base is weak. (Section 17.3)
- Given either K_{sp} , molar solubility or mass solubility for a substance calculate the other two quantities. (Section 17.4)
- Calculate molar solubility in the presence of a common ion. (Section 17.5)
- Predict the effect of pH on solubility. (Section 17.5)
- Predict whether a precipitate will form when solutions are mixed by comparing Q and K_{sp} . (Section 17.6)
- Calculate the ion concentrations required to begin precipitation. (Section 17.6)
- Explain the effect of complex-ion formation on solubility. (Section 17.6)

KEY EQUATION

- $$\text{pH} = \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]}$$
 [17.9] The Henderson–Hasselbalch equation, used to calculate the pH of a buffer from the concentrations of a conjugate acid–base pair

EXERCISES

VISUALIZING CONCEPTS

- 17.1** The following boxes represent aqueous solutions containing a weak acid, HX, and its conjugate base, X^- . Water molecules, hydronium ions and cations are not shown. Which solution has the highest pH? Explain. [Section 17.1]

- 17.2** The beaker on the right contains 0.1 M acetic acid solution with methyl orange as an indicator. The beaker on the left contains a mixture of 0.1 M acetic acid and 0.1 M sodium acetate with methyl orange. (a) Using Figure 16.7, what can you say about the pH of each solution? (b) Which solution is better able to maintain its pH when small amounts of NaOH are added? Explain. [Sections 17.1 and 17.2]

- 17.3** A buffer contains a weak acid, HX, and its conjugate base. The weak acid has a $\text{p}K_a$ of 4.5, and the buffer has a pH of 4.3. Without doing a calculation, predict whether $[\text{HX}] = [\text{X}^-]$, $[\text{HX}] > [\text{X}^-]$, or $[\text{HX}] < [\text{X}^-]$. Explain. [Section 17.2]

- 17.4** The drawing on the left represents a buffer composed of equal concentrations of a weak acid, HX, and its conjugate base, X^- . The heights of the columns are proportional to the concentrations of the components of the buffer. (a) Which of the three drawings, (1), (2), or (3), represents the buffer after the addition of a strong acid? (b) Which of the three represents the buffer after the addition of a strong base? (c) Which of the three represents a situation that cannot arise from the addition of either an acid or a base? [Section 17.2]

- 17.5** The following drawings represent solutions at various stages of the titration of a weak acid, HA, with NaOH. (The Na^+ ions and water molecules have been omitted for clarity.) To which of the following regions of the titration curve does each drawing correspond: (a) before addition of NaOH, (b) after

addition of NaOH but before equivalence point, (c) at equivalence point, (d) after equivalence point? [Section 17.3]

17.6 Match the following descriptions of titration curves with the diagrams: (a) strong acid added to strong base, (b) strong base added to weak acid, (c) strong base added to strong acid, (d) strong base added to polyprotic acid. [Section 17.3]

17.7 Equal volumes of two acids are titrated with 0.10 M NaOH resulting in the two titration curves shown in the following figure. (a) Which curve corresponds to the more concentrated acid solution? (b) Which corresponds to the acid with the larger K_a ? Explain. [Section 17.3]

17.8 A saturated solution of $\text{Cd}(\text{OH})_2$ is shown in the middle beaker. If hydrochloric acid solution is added, the solubility of

$\text{Cd}(\text{OH})_2$ will increase, causing additional solid to dissolve. Which of the two choices, Beaker A or Beaker B, accurately represents the solution after equilibrium is reestablished? Explain. (The water molecules and Cl^{-} ions are omitted for clarity). [Sections 17.4 and 17.5]

17.9 The following graphs represent the behavior of BaCO_3 under different circumstances. In each case the vertical axis indicates the solubility of the BaCO_3 and the horizontal axis represents the concentration of some other reagent. (a) Which graph represents what happens to the solubility of BaCO_3 as HNO_3 is added? (b) Which graph represents what happens to the BaCO_3 solubility as Na_2CO_3 is added? (c) Which represents what happens to the BaCO_3 solubility as NaNO_3 is added? [Section 17.5]

17.10 $\text{Ca}(\text{OH})_2$ has a K_{sp} of 6.5×10^{-6} . (a) If 0.370 g of $\text{Ca}(\text{OH})_2$ is added to 500 mL of water and the mixture is allowed to come to equilibrium, will the solution be saturated? (b) If 50 mL of the solution from part (a) is added to each of the beakers shown here, in which beakers, if any, will a precipitate form? In those cases where a precipitate forms, what is its identity? [Section 17.6]

17.11 What is the name given to the kind of behavior demonstrated by a metal hydroxide in this graph? [Section 17.5]

- 17.12 Three cations, Ni^{2+} , Cu^{2+} , and Ag^{+} , are separated using two different precipitating agents. Based on Figure 17.23, what two precipitating agents could be used? Using these agents, indicate which of the cations is A, which is B, and which is C. [Section 17.7]

COMMON-ION EFFECT (section 17.1)

- 17.13 (a) What is the common-ion effect? (b) Give an example of a salt that can decrease the ionization of HNO_2 in solution.
- 17.14 (a) Consider the equilibrium $\text{B}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{HB}^+(aq) + \text{OH}^-(aq)$. Using Le Châtelier's principle, explain the effect of the presence of a salt of HB^+ on the ionization of B. (b) Give an example of a salt that can decrease the ionization of NH_3 in solution.
- 17.15 Use information from Appendix D to calculate the pH of (a) a solution that is 0.060 M in potassium propionate ($\text{C}_2\text{H}_5\text{COOK}$ or $\text{KC}_2\text{H}_5\text{O}_2$) and 0.085 M in propionic acid ($\text{C}_2\text{H}_5\text{COOH}$ or $\text{HC}_2\text{H}_5\text{O}_2$); (b) a solution that is 0.075 M in trimethylamine, $(\text{CH}_3)_3\text{N}$, and 0.10 M in trimethylammonium chloride, $(\text{CH}_3)_3\text{NHCl}$; (c) a solution that is made by mixing 50.0 mL of 0.15 M acetic acid and 50.0 mL of 0.20 M sodium acetate.

- 17.16 Use information from Appendix D to calculate the pH of (a) a solution that is 0.250 M in sodium formate (HCOONa) and 0.100 M in formic acid (HCOOH); (b) a solution that is 0.510 M in pyridine ($\text{C}_5\text{H}_5\text{N}$) and 0.450 M in pyridinium chloride ($\text{C}_5\text{H}_5\text{NHCl}$); (c) a solution that is made by combining 55 mL of 0.050 M hydrofluoric acid with 125 mL of 0.10 M sodium fluoride.

- 17.17 (a) Calculate the percent ionization of 0.0075 M butanoic acid ($K_a = 1.5 \times 10^{-5}$). (b) Calculate the percent ionization of 0.0075 M butanoic acid in a solution containing 0.085 M sodium butanoate.
- 17.18 (a) Calculate the percent ionization of 0.125 M lactic acid ($K_a = 1.4 \times 10^{-4}$). (b) Calculate the percent ionization of 0.125 M lactic acid in a solution containing 0.0075 M sodium lactate.

BUFFERED SOLUTIONS (section 17.2)

- 17.19 Explain why a mixture of CH_3COOH and CH_3COONa can act as a buffer while a mixture of HCl and NaCl cannot.
- 17.20 Explain why a mixture formed by mixing 100 mL of 0.100 M CH_3COOH and 50 mL of 0.100 M NaOH will act as a buffer.
- 17.21 (a) Calculate the pH of a buffer that is 0.12 M in lactic acid and 0.11 M in sodium lactate. (b) Calculate the pH of a buffer formed by mixing 85 mL of 0.13 M lactic acid with 95 mL of 0.15 M sodium lactate.
- 17.22 (a) Calculate the pH of a buffer that is 0.105 M in NaHCO_3 and 0.125 M in Na_2CO_3 . (b) Calculate the pH of a solution formed by mixing 65 mL of 0.20 M NaHCO_3 with 75 mL of 0.15 M Na_2CO_3 .
- 17.23 A buffer is prepared by adding 20.0 g of sodium acetate (CH_3COONa) to 500 mL of a 0.150 M acetic acid (CH_3COOH) solution. (a) Determine the pH of the buffer. (b) Write the complete ionic equation for the reaction that occurs when a few drops of hydrochloric acid are added to the buffer. (c) Write the complete ionic equation for the reaction that occurs when a few drops of sodium hydroxide solution are added to the buffer.
- 17.24 A buffer is prepared by adding 10.0 g of ammonium chloride (NH_4Cl) to 250 mL of 1.00 M NH_3 solution. (a) What is the pH of this buffer? (b) Write the complete ionic equation for the reaction that occurs when a few drops of nitric acid are

added to the buffer. (c) Write the complete ionic equation for the reaction that occurs when a few drops of potassium hydroxide solution are added to the buffer.

- 17.25 You are asked to prepare a pH = 3.00 buffer solution starting from 1.25 L of a 1.00 M solution of hydrofluoric acid (HF) and an excess of sodium fluoride (NaF). (a) What is the pH of the hydrofluoric acid solution prior to adding sodium fluoride? (b) How many grams of sodium fluoride should be added to prepare the buffer solution? Neglect the small volume change that occurs when the sodium fluoride is added.
- 17.26 You are asked to prepare a pH = 4.00 buffer starting from 1.50 L of 0.0200 M solution of benzoic acid ($\text{C}_6\text{H}_5\text{COOH}$) and an excess of sodium benzoate ($\text{C}_6\text{H}_5\text{COONa}$). (a) What is the pH of the benzoic acid solution prior to adding sodium benzoate? (b) How many grams of sodium benzoate should be added to prepare the buffer? Neglect the small volume change that occurs when the sodium benzoate is added.
- 17.27 A buffer contains 0.10 mol of acetic acid and 0.13 mol of sodium acetate in 1.00 L. (a) What is the pH of this buffer? (b) What is the pH of the buffer after the addition of 0.02 mol of KOH ? (c) What is the pH of the buffer after the addition of 0.02 mol of HNO_3 ?

- 17.28 A buffer contains 0.15 mol of propionic acid (C_2H_5COOH) and 0.10 mol of sodium propionate (C_2H_5COONa) in 1.20 L. (a) What is the pH of this buffer? (b) What is the pH of the buffer after the addition of 0.01 mol of NaOH? (c) What is the pH of the buffer after the addition of 0.01 mol of HI?
- 17.29 (a) What is the ratio of HCO_3^- to H_2CO_3 in blood of pH 7.4? (b) What is the ratio of HCO_3^- to H_2CO_3 in an exhausted marathon runner whose blood pH is 7.1?
- 17.30 A buffer, consisting of $H_2PO_4^-$ and HPO_4^{2-} , helps control the pH of physiological fluids. Many carbonated soft drinks also use this buffer system. What is the pH of a soft drink in which

the major buffer ingredients are 6.5 g of NaH_2PO_4 and 8.0 g of Na_2HPO_4 per 355 mL of solution?

- 17.31 You have to prepare a pH 3.50 buffer, and you have the following 0.10 M solutions available: $HCOOH$, CH_3COOH , H_3PO_4 , $HCOONa$, CH_3COONa , and NaH_2PO_4 . Which solutions would you use? How many milliliters of each solution would you use to make approximately a liter of the buffer?
- 17.32 You have to prepare a pH 5.00 buffer, and you have the following 0.10 M solutions available: $HCOOH$, $HCOONa$, CH_3COOH , CH_3COONa , HCN , and $NaCN$. Which solutions would you use? How many milliliters of each solution would you use to make approximately a liter of the buffer?

ACID-BASE TITRATIONS (section 17.3)

- 17.33 The accompanying graph shows the titration curves for two monoprotic acids. (a) Which curve is that of a strong acid? (b) What is the approximate pH at the equivalence point of each titration? (c) 40.0 mL of each acid was titrated with 0.100 M base. Which acid is more concentrated?

- 17.34 How does titration of a strong, monoprotic acid with a strong base differ from titration of a weak, monoprotic acid with a strong base with respect to the following: (a) quantity of base required to reach the equivalence point, (b) pH at the beginning of the titration, (c) pH at the equivalence point, (d) pH after addition of a slight excess of base, (e) choice of indicator for determining the equivalence point?
- 17.35 The samples of nitric and acetic acid shown here are both titrated with a 0.100 M solution of NaOH(aq).

25.0 mL of 1.0 M $HNO_3(aq)$ 25.0 mL of 1.0 M $CH_3COOH(aq)$

Determine whether each of the following statements concerning these titrations is true or false.

- (a) A larger volume of NaOH(aq) is needed to reach the equivalence point in the titration of HNO_3 .

- (b) The pH at the equivalence point in the HNO_3 titration will be lower than the pH at the equivalence point in the CH_3COOH titration.
- (c) Phenolphthalein would be a suitable indicator for both titrations.

- 17.36 Determine whether each of the following statements concerning the titrations in Problem 17.35 is true or false.

- (a) The pH at the beginning of the two titrations will be the same.
- (b) The titration curves will both be essentially the same after passing the equivalence point.
- (c) Methyl red would be a suitable indicator for both titrations.

- 17.37 Predict whether the equivalence point of each of the following titrations is below, above, or at pH 7: (a) $NaHCO_3$ titrated with NaOH, (b) NH_3 titrated with HCl, (c) KOH titrated with HBr.

- 17.38 Predict whether the equivalence point of each of the following titrations is below, above, or at pH 7: (a) formic acid titrated with NaOH, (b) calcium hydroxide titrated with perchloric acid, (c) pyridine titrated with nitric acid.

- 17.39 As shown in Figure 16.7, the indicator thymol blue has two color changes. Which color change will generally be more suitable for titration of a weak acid with a strong base?

- 17.40 Assume that 30.0 mL of a 0.10 M solution of a weak base B that accepts one proton is titrated with a 0.10 M solution of the monoprotic strong acid HX. (a) How many moles of HX have been added at the equivalence point? (b) What is the predominant form of B at the equivalence point? (c) What factor determines the pH at the equivalence point? (d) Which indicator, phenolphthalein or methyl red, is likely to be the better choice for this titration?

- 17.41 How many milliliters of 0.0850 M NaOH are required to titrate each of the following solutions to the equivalence point: (a) 40.0 mL of 0.0900 M HNO_3 , (b) 35.0 mL of 0.0850 M CH_3COOH , (c) 50.0 mL of a solution that contains 1.85 g of HCl per liter?

- 17.42 How many milliliters of 0.105 M HCl are needed to titrate each of the following solutions to the equivalence point: (a) 45.0 mL of 0.0950 M NaOH, (b) 22.5 mL of 0.118 M NH_3 , (c) 125.0 mL of a solution that contains 1.35 g of NaOH per liter?

- 17.43 A 20.0-mL sample of 0.200 M HBr solution is titrated with 0.200 M NaOH solution. Calculate the pH of the solution after the following volumes of base have been added: (a) 15.0 mL, (b) 19.9 mL, (c) 20.0 mL, (d) 20.1 mL, (e) 35.0 mL.

- 17.44 A 20.0-mL sample of 0.150 M KOH is titrated with 0.125 M HClO₄ solution. Calculate the pH after the following volumes of acid have been added: (a) 20.0 mL, (b) 23.0 mL, (c) 24.0 mL, (d) 25.0 mL, (e) 30.0 mL.
- 17.45 A 35.0-mL sample of 0.150 M acetic acid (CH₃COOH) is titrated with 0.150 M NaOH solution. Calculate the pH after the following volumes of base have been added: (a) 0 mL, (b) 17.5 mL, (c) 34.5 mL, (d) 35.0 mL, (e) 35.5 mL, (f) 50.0 mL.
- 17.46 Consider the titration of 30.0 mL of 0.050 M NH₃ with 0.025 M HCl. Calculate the pH after the following volumes of titrant have been added: (a) 0 mL, (b) 20.0 mL, (c) 59.0 mL, (d) 60.0 mL, (e) 61.0 mL, (f) 65.0 mL.
- 17.47 Calculate the pH at the equivalence point for titrating 0.200 M solutions of each of the following bases with 0.200 M HBr: (a) sodium hydroxide (NaOH), (b) hydroxylamine (NH₂OH), (c) aniline (C₆H₅NH₂).
- 17.48 Calculate the pH at the equivalence point in titrating 0.100 M solutions of each of the following with 0.080 M NaOH: (a) hydrobromic acid (HBr), (b) chlorous acid (HClO₂), (c) benzoic acid (C₆H₅COOH).

SOLUBILITY EQUILIBRIA AND FACTORS AFFECTING SOLUBILITY (sections 17.4 and 17.5)

- 17.49 (a) Why is the concentration of undissolved solid not explicitly included in the expression for the solubility-product constant? (b) Write the expression for the solubility-product constant for each of the following strong electrolytes: AgI, SrSO₄, Fe(OH)₂, and Hg₂Br₂.
- 17.50 (a) Explain the difference between solubility and solubility-product constant. (b) Write the expression for the solubility-product constant for each of the following ionic compounds: MnCO₃, Hg(OH)₂, and Cu₃(PO₄)₂.
- 17.51 (a) If the molar solubility of CaF₂ at 35 °C is 1.24×10^{-3} mol/L, what is K_{sp} at this temperature? (b) It is found that 1.1×10^{-2} of SrF₂ dissolves per 100 mL of aqueous solution at 25 °C. Calculate the solubility product for SrF₂. (c) The K_{sp} of Ba(IO₃)₂ at 25 °C is 6.0×10^{-10} . What is the molar solubility of Ba(IO₃)₂?
- 17.52 (a) The molar solubility of PbBr₂ at 25 °C is 1.0×10^{-2} mol/L. Calculate K_{sp} . (b) If 0.0490 g of AgIO₃ dissolves per liter of solution, calculate the solubility-product constant. (c) Using the appropriate K_{sp} value from Appendix D, calculate the pH of a saturated solution of Ca(OH)₂.
- 17.53 A 1.00-L solution saturated at 25 °C with calcium oxalate (CaC₂O₄) contains 0.0061 g of CaC₂O₄. Calculate the solubility-product constant for this salt at 25 °C.
- 17.54 A 1.00-L solution saturated at 25 °C with lead(II) iodide contains 0.54 g of PbI₂. Calculate the solubility-product constant for this salt at 25 °C.
- 17.55 Using Appendix D, calculate the molar solubility of AgBr in (a) pure water, (b) 3.0×10^{-2} M AgNO₃ solution, (c) 0.10 M NaBr solution.
- 17.56 Calculate the solubility of LaF₃ in grams per liter in (a) pure water, (b) 0.010 M KF solution, (c) 0.050 M LaCl₃ solution.
- 17.57 Consider a beaker containing a saturated solution of CaF₂ in equilibrium with undissolved CaF₂(s). (a) If solid CaCl₂ is added to this solution, will the amount of solid CaF₂ at the bottom of the beaker increase, decrease, or remain the same? (b) Will the concentration of Ca²⁺ ions in solution increase or decrease? (c) Will the concentration of F⁻ ions in solution increase or decrease?
- 17.58 Consider a beaker containing a saturated solution of PbI₂ in equilibrium with undissolved PbI₂(s). (a) If solid KI is added to this solution, will the amount of solid PbI₂ at the bottom of the beaker increase, decrease, or remain the same? (b) Will the concentration of Pb²⁺ ions in solution increase or decrease? (c) Will the concentration of I⁻ ions in solution increase or decrease?
- 17.59 Calculate the solubility of Mn(OH)₂ in grams per liter when buffered at pH (a) 7.0, (b) 9.5, (c) 11.8.
- 17.60 Calculate the molar solubility of Ni(OH)₂ when buffered at pH (a) 8.0, (b) 10.0, (c) 12.0.
- 17.61 Which of the following salts will be substantially more soluble in acidic solution than in pure water: (a) ZnCO₃, (b) ZnS, (c) BiI₃, (d) AgCN, (e) Ba₃(PO₄)₂?
- 17.62 For each of the following slightly soluble salts, write the net ionic equation, if any, for reaction with acid: (a) MnS, (b) PbF₂, (c) AuCl₃, (d) Hg₂C₂O₄, (e) CuBr.
- 17.63 From the value of K_f listed in Table 17.1, calculate the concentration of Ni²⁺ in 1.0 L of a solution that contains a total of 1×10^{-3} mol of nickel(II) ion and that is 0.20 M in NH₃.
- 17.64 To what final concentration of NH₃ must a solution be adjusted to just dissolve 0.020 mol of NiC₂O₄ ($K_{sp} = 4 \times 10^{-10}$) in 1.0 L of solution? (*Hint*: You can neglect the hydrolysis of C₂O₄²⁻ because the solution will be quite basic.)
- 17.65 Use values of K_{sp} for AgI and K_f for Ag(CN)₂⁻ to (a) calculate the molar solubility of AgI in pure water, (b) calculate the equilibrium constant for the reaction
- $$\text{AgI}(s) + 2 \text{CN}^-(aq) \rightleftharpoons \text{Ag}(\text{CN})_2^-(aq) + \text{I}^-(aq)$$
- (c) Determine the molar solubility of AgI in a 0.100 M NaCN solution.
- 17.66 Using the value of K_{sp} for Ag₂S, K_{a1} and K_{a2} for H₂S, and $K_f = 1.1 \times 10^5$ for AgCl₂⁻, calculate the equilibrium constant for the following reaction:
- $$\text{Ag}_2\text{S}(s) + 4 \text{Cl}^-(aq) + 2 \text{H}^+(aq) \rightleftharpoons 2 \text{AgCl}_2^-(aq) + \text{H}_2\text{S}(aq)$$

PRECIPITATION AND SEPARATION OF IONS (section 17.6)

- 17.67** (a) Will $\text{Ca}(\text{OH})_2$ precipitate from solution if the pH of a 0.050 M solution of CaCl_2 is adjusted to 8.0? (b) Will Ag_2SO_4 precipitate when 100 mL of 0.050 M AgNO_3 is mixed with 10 mL of 5.0×10^{-2} M Na_2SO_4 solution?
- 17.68** (a) Will $\text{Co}(\text{OH})_2$ precipitate from solution if the pH of a 0.020 M solution of $\text{Co}(\text{NO}_3)_2$ is adjusted to 8.5? (b) Will AgIO_3 precipitate when 20 mL of 0.010 M AgNO_3 is mixed with 10 mL of 0.015 M NaIO_3 ? (K_{sp} of AgIO_3 is 3.1×10^{-8} .)
- 17.69** Calculate the minimum pH needed to precipitate $\text{Mn}(\text{OH})_2$ so completely that the concentration of Mn^{2+} is less than 1 μg per liter [1 part per billion (ppb)].
- 17.70** Suppose that a 10-mL sample of a solution is to be tested for Γ^- ion by addition of 1 drop (0.2 mL) of 0.10 M $\text{Pb}(\text{NO}_3)_2$. What is the minimum number of grams of Γ^- that must be present for $\text{PbI}_2(s)$ to form?
- 17.71** A solution contains 2.0×10^{-4} M Ag^+ and 1.5×10^{-3} M Pb^{2+} . If NaI is added, will AgI ($K_{sp} = 8.3 \times 10^{-17}$) or PbI_2 ($K_{sp} = 7.9 \times 10^{-9}$) precipitate first? Specify the concentration of Γ^- needed to begin precipitation.
- 17.72** A solution of Na_2SO_4 is added dropwise to a solution that is 0.010 M in Ba^{2+} and 0.010 M in Sr^{2+} . (a) What concentration of SO_4^{2-} is necessary to begin precipitation? (Neglect volume changes. BaSO_4 : $K_{sp} = 1.1 \times 10^{-10}$; SrSO_4 : $K_{sp} = 3.2 \times 10^{-7}$.) (b) Which cation precipitates first? (c) What is the concentration of SO_4^{2-} when the second cation begins to precipitate?
- 17.73** A solution contains three anions with the following concentrations: 0.20 M CrO_4^{2-} , 0.10 M CO_3^{2-} , and 0.010 M Cl^- . If a dilute AgNO_3 solution is slowly added to the solution, what is the first compound to precipitate: Ag_2CrO_4 ($K_{sp} = 1.2 \times 10^{-12}$), Ag_2CO_3 ($K_{sp} = 8.1 \times 10^{-12}$), or AgCl ($K_{sp} = 1.8 \times 10^{-10}$)?
- 17.74** A 1.0 M Na_2SO_4 solution is slowly added to 10.0 mL of a solution that is 0.20 M in Ca^{2+} and 0.30 M in Ag^+ . (a) Which compound will precipitate first: CaSO_4 ($K_{sp} = 2.4 \times 10^{-5}$) or Ag_2SO_4 ($K_{sp} = 1.5 \times 10^{-5}$)? (b) How much Na_2SO_4 solution must be added to initiate the precipitation?

QUALITATIVE ANALYSIS FOR METALLIC ELEMENTS (section 17.7)

- 17.75** A solution containing an unknown number of metal ions is treated with dilute HCl ; no precipitate forms. The pH is adjusted to about 1, and H_2S is bubbled through. Again, no precipitate forms. The pH of the solution is then adjusted to about 8. Again, H_2S is bubbled through. This time a precipitate forms. The filtrate from this solution is treated with $(\text{NH}_4)_2\text{HPO}_4$. No precipitate forms. Which metal ions discussed in Section 17.7 are possibly present? Which are definitely absent within the limits of these tests?
- 17.76** An unknown solid is entirely soluble in water. On addition of dilute HCl , a precipitate forms. After the precipitate is filtered off, the pH is adjusted to about 1 and H_2S is bubbled in; a precipitate again forms. After filtering off this precipitate, the pH is adjusted to 8 and H_2S is again added; no precipitate forms. No precipitate forms upon addition of $(\text{NH}_4)_2\text{HPO}_4$. The remaining solution shows a yellow color in a flame test (see Figure 7.21). Based on these observations, which of the following compounds might be present, which are definitely present, and which are definitely absent: CdS , $\text{Pb}(\text{NO}_3)_2$, HgO , ZnSO_4 , $\text{Cd}(\text{NO}_3)_2$, and Na_2SO_4 ?
- 17.77** In the course of various qualitative analysis procedures, the following mixtures are encountered: (a) Zn^{2+} and Cd^{2+} , (b) $\text{Cr}(\text{OH})_3$ and $\text{Fe}(\text{OH})_3$, (c) Mg^{2+} and K^+ , (d) Ag^+ and Mn^{2+} . Suggest how each mixture might be separated.
- 17.78** Suggest how the cations in each of the following solution mixtures can be separated: (a) Na^+ and Cd^{2+} , (b) Cu^{2+} and Mg^{2+} , (c) Pb^{2+} and Al^{3+} , (d) Ag^+ and Hg^{2+} .
- 17.79** (a) Precipitation of the group 4 cations of Figure 17.23 requires a basic medium. Why is this so? (b) What is the most significant difference between the sulfides precipitated in group 2 and those precipitated in group 3? (c) Suggest a procedure that would serve to redissolve the group 3 cations following their precipitation.
- 17.80** A student who is in a great hurry to finish his laboratory work decides that his qualitative analysis unknown contains a metal ion from group 4 of Figure 17.23. He therefore tests his sample directly with $(\text{NH}_4)_2\text{HPO}_4$, skipping earlier tests for the metal ions in groups 1, 2, and 3. He observes a precipitate and concludes that a metal ion from group 4 is indeed present. Why is this possibly an erroneous conclusion?

ADDITIONAL EXERCISES

- 17.81** Derive an equation similar to the Henderson–Hasselbalch equation relating the pOH of a buffer to the pK_b of its base component.
- 17.82** Benzenesulfonic acid is a monoprotic acid with $pK_a = 2.25$. Calculate the pH of a buffer composed of 0.150 M benzenesulfonic acid and 0.125 M sodium benzenesulfonate.
- 17.83** Furoic acid ($\text{HC}_5\text{H}_3\text{O}_3$) has a K_a value of 6.76×10^{-4} at 25 °C. Calculate the pH at 25 °C of (a) a solution formed by adding 25.0 g of furoic acid and 30.0 g of sodium furoate ($\text{NaC}_5\text{H}_3\text{O}_3$) to enough water to form 0.250 L of solution; (b) a solution formed by mixing 30.0 mL of 0.250 M $\text{HC}_5\text{H}_3\text{O}_3$ and 20.0 mL of 0.22 M $\text{NaC}_5\text{H}_3\text{O}_3$ and diluting the total volume to 125 mL; (c) a solution prepared by adding 50.0 mL of 1.65 M NaOH solution to 0.500 L of 0.0850 M $\text{HC}_5\text{H}_3\text{O}_3$.
- 17.84** The acid–base indicator bromocresol green is a weak acid. The yellow acid and blue base forms of the indicator are present in equal concentrations in a solution when the pH is 4.68. What is the pK_a for bromocresol green?
- 17.85** Equal quantities of 0.010 M solutions of an acid HA and a base B are mixed. The pH of the resulting solution is 9.2. (a) Write the equilibrium equation and equilibrium-constant expression for the reaction between HA and B. (b) If K_a for HA is 8.0×10^{-5} , what is the value of the equilibrium constant for the reaction between HA and B? (c) What is the value of K_b for B?
- 17.86** Two buffers are prepared by adding an equal number of moles of formic acid (HCOOH) and sodium formate (HCOONa) to enough water to make 1.00 L of solution. Buffer A is prepared using 1.00 mol each of formic acid and sodium formate. Buffer B is prepared by using 0.010 mol of each. (a) Calculate the pH of each buffer, and explain why they are equal. (b) Which buffer will have the greater buffer capacity? Explain. (c) Calculate the change in pH for each buffer upon the addition of 1.0 mL of 1.00 M HCl. (d) Calculate the change in pH for each buffer upon the addition of 10 mL of 1.00 M HCl. (e) Discuss your answers for parts (c) and (d) in light of your response to part (b).
- 17.87** A biochemist needs 750 mL of an acetic acid–sodium acetate buffer with pH 4.50. Solid sodium acetate (CH_3COONa) and glacial acetic acid (CH_3COOH) are available. Glacial acetic acid is 99% CH_3COOH by mass and has a density of 1.05 g/mL. If the buffer is to be 0.15 M in CH_3COOH , how many grams of CH_3COONa and how many milliliters of glacial acetic acid must be used?
- 17.88** A sample of 0.2140 g of an unknown monoprotic acid was dissolved in 25.0 mL of water and titrated with 0.0950 M NaOH. The acid required 27.4 mL of base to reach the equivalence point. (a) What is the molar mass of the acid? (b) After 15.0 mL of base had been added in the titration, the pH was found to be 6.50. What is the K_a for the unknown acid?
- 17.89** A sample of 0.1687 g of an unknown monoprotic acid was dissolved in 25.0 mL of water and titrated with 0.1150 M NaOH. The acid required 15.5 mL of base to reach the equivalence point. (a) What is the molecular weight of the acid? (b) After 7.25 mL of base had been added in the titration, the pH was found to be 2.85. What is the K_a for the unknown acid?
- 17.90** Show that the pH at the halfway point of a titration of a weak acid with a strong base (where the volume of added base is half of that needed to reach the equivalence point) is equal to pK_a for the acid.
- 17.91** A hypothetical weak acid, HA, was combined with NaOH in the following proportions: 0.20 mol of HA, 0.080 mol of NaOH. The mixture was diluted to a total volume of 1.0 L and the pH measured. (a) If pH = 4.80, what is the pK_a of the acid? (b) How many additional moles of NaOH should be added to the solution to increase the pH to 5.00?
- [17.92]** What is the pH of a solution made by mixing 0.30 mol NaOH, 0.25 mol Na_2HPO_4 , and 0.20 mol H_3PO_4 with water and diluting to 1.00 L?
- [17.93]** Suppose you want to do a physiological experiment that calls for a pH 6.50 buffer. You find that the organism with which you are working is not sensitive to the weak acid H_2X ($K_{a1} = 2 \times 10^{-2}$; $K_{a2} = 5.0 \times 10^{-7}$) or its sodium salts. You have available a 1.0 M solution of this acid and a 1.0 M solution of NaOH. How much of the NaOH solution should be added to 1.0 L of the acid to give a buffer at pH 6.50? (Ignore any volume change.)
- [17.94]** How many microliters of 1.000 M NaOH solution must be added to 25.00 mL of a 0.1000 M solution of lactic acid [$\text{CH}_3\text{CH}(\text{OH})\text{COOH}$ or $\text{HC}_3\text{H}_5\text{O}_3$] to produce a buffer with pH = 3.75?
- 17.95** A person suffering from anxiety begins breathing rapidly and as a result suffers alkalosis, an increase in blood pH. (a) Using Equation 17.10, explain how rapid breathing can cause the pH of blood to increase. (b) One cure for this problem is breathing in a paper bag. Why does this procedure lower blood pH?
- 17.96** For each pair of compounds, use K_{sp} values to determine which has the greater molar solubility: (a) CdS or CuS, (b) PbCO_3 or BaCrO_4 , (c) $\text{Ni}(\text{OH})_2$ or NiCO_3 , (d) AgI or Ag_2SO_4 .
- 17.97** The solubility of CaCO_3 is pH dependent. (a) Calculate the molar solubility of CaCO_3 ($K_{sp} = 4.5 \times 10^{-9}$) neglecting the acid–base character of the carbonate ion. (b) Use the K_b expression for the CO_3^{2-} ion to determine the equilibrium constant for the reaction
- $$\text{CaCO}_3(\text{s}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{Ca}^{2+}(\text{aq}) + \text{HCO}_3^-(\text{aq}) + \text{OH}^-(\text{aq})$$
- (c) If we assume that the only sources of Ca^{2+} , HCO_3^- , and OH^- ions are from the dissolution of CaCO_3 , what is the molar solubility of CaCO_3 using the preceding expression? What is the pH? (d) If the pH is buffered at 8.2 (as is historically typical for the ocean), what is the molar solubility of CaCO_3 ? (e) If the pH is buffered at 7.5, what is the molar solubility of CaCO_3 ? How much does this drop in pH increase solubility?
- 17.98** Tooth enamel is composed of hydroxyapatite, whose simplest formula is $\text{Ca}_5(\text{PO}_4)_3\text{OH}$, and whose corresponding $K_{sp} = 6.8 \times 10^{-27}$. As discussed in the “Chemistry and Life” box on page 730, fluoride in fluorinated water or in toothpaste reacts with hydroxyapatite to form fluoroapatite, $\text{Ca}_5(\text{PO}_4)_3\text{F}$, whose $K_{sp} = 1.0 \times 10^{-60}$. (a) Write the expression for the solubility-constant for hydroxyapatite and for fluoroapatite. (b) Calculate the molar solubility of each of these compounds.

- 17.99** Use the solubility-product constant for $\text{Cr}(\text{OH})_3$ ($K_{sp} = 6.7 \times 10^{-31}$) and the formation constant for $\text{Cr}(\text{OH})_4^-$ from Table 17.1 to determine the concentration of $\text{Cr}(\text{OH})_4^-$ in a solution that is buffered at $\text{pH} = 10.0$ and is in equilibrium with solid $\text{Cr}(\text{OH})_3$.
- 17.100** Calculate the solubility of $\text{Mg}(\text{OH})_2$ in $0.50 \text{ M NH}_4\text{Cl}$.
- 17.101** The solubility-product constant for barium permanganate, $\text{Ba}(\text{MnO}_4)_2$, is 2.5×10^{-10} . Assume that solid $\text{Ba}(\text{MnO}_4)_2$ is in equilibrium with a solution of KMnO_4 . What concentration of KMnO_4 is required to establish a concentration of $2.0 \times 10^{-8} \text{ M}$ for the Ba^{2+} ion in solution?
- 17.102** Calculate the ratio of $[\text{Ca}^{2+}]$ to $[\text{Fe}^{2+}]$ in a lake in which the water is in equilibrium with deposits of both CaCO_3 and FeCO_3 . Assume that the water is slightly basic and that the hydrolysis of the carbonate ion can therefore be ignored.
- [17.103]** The solubility products of PbSO_4 and SrSO_4 are 6.3×10^{-7} and 3.2×10^{-7} , respectively. What are the values of $[\text{SO}_4^{2-}]$, $[\text{Pb}^{2+}]$, and $[\text{Sr}^{2+}]$ in a solution at equilibrium with both substances?
- [17.104]** A buffer of what pH is needed to give a Mg^{2+} concentration of $3.0 \times 10^{-2} \text{ M}$ in equilibrium with solid magnesium oxalate?
- [17.105]** The value of K_{sp} for $\text{Mg}_3(\text{AsO}_4)_2$ is 2.1×10^{-20} . The AsO_4^{3-} ion is derived from the weak acid H_3AsO_4 ($\text{p}K_{a1} = 2.22$; $\text{p}K_{a2} = 6.98$; $\text{p}K_{a3} = 11.50$). When asked to calculate the molar solubility of $\text{Mg}_3(\text{AsO}_4)_2$ in water, a student used the K_{sp} expression and assumed that $[\text{Mg}^{2+}] = 1.5[\text{AsO}_4^{3-}]$. Why was this a mistake?
- [17.106]** The solubility product for $\text{Zn}(\text{OH})_2$ is 3.0×10^{-16} . The formation constant for the hydroxo complex, $\text{Zn}(\text{OH})_4^{2-}$, is 4.6×10^{17} . What concentration of OH^- is required to dissolve 0.015 mol of $\text{Zn}(\text{OH})_2$ in a liter of solution?
- [17.107]** The value of K_{sp} for $\text{Cd}(\text{OH})_2$ is 2.5×10^{-14} . (a) What is the molar solubility of $\text{Cd}(\text{OH})_2$? (b) The solubility of $\text{Cd}(\text{OH})_2$ can be increased through formation of the complex ion CdBr_4^{2-} ($K_f = 5 \times 10^3$). If solid $\text{Cd}(\text{OH})_2$ is added to a NaBr solution, what would the initial concentration of NaBr need to be in order to increase the molar solubility of $\text{Cd}(\text{OH})_2$ to 1.0×10^{-3} moles per liter?

INTEGRATIVE EXERCISES

- 17.108** (a) Write the net ionic equation for the reaction that occurs when a solution of hydrochloric acid (HCl) is mixed with a solution of sodium formate (NaCHO_2). (b) Calculate the equilibrium constant for this reaction. (c) Calculate the equilibrium concentrations of Na^+ , Cl^- , H^+ , CHO_2^- , and HCHO_2 when 50.0 mL of 0.15 M HCl is mixed with 50.0 mL of 0.15 M NaCHO_2 .
- 17.109** (a) A 0.1044-g sample of an unknown monoprotic acid requires 22.10 mL of 0.0500 M NaOH to reach the end point. What is the molecular weight of the unknown? (b) As the acid is titrated, the pH of the solution after the addition of 11.05 mL of the base is 4.89 . What is the K_a for the acid? (c) Using Appendix D, suggest the identity of the acid. Do both the molecular weight and K_a value agree with your choice?
- 17.110** A sample of 7.5 L of NH_3 gas at 22°C and 735 torr is bubbled into a 0.50-L solution of 0.40 M HCl . Assuming that all the NH_3 dissolves and that the volume of the solution remains 0.50 L , calculate the pH of the resulting solution.
- 17.111** Aspirin has the structural formula

At body temperature (37°C), K_a for aspirin equals 3×10^{-5} . If two aspirin tablets, each having a mass of 325 mg , are dissolved in a full stomach whose volume is 1 L and whose pH is 2 , what percent of the aspirin is in the form of neutral molecules?

- 17.112** What is the pH at 25°C of water saturated with CO_2 at a partial pressure of 1.10 atm ? The Henry's law constant for CO_2 at 25°C is $3.1 \times 10^{-2} \text{ mol/L-atm}$. The CO_2 is an acidic oxide, reacting with H_2O to form H_2CO_3 .
- 17.113** Excess $\text{Ca}(\text{OH})_2$ is shaken with water to produce a saturated solution. The solution is filtered, and a 50.00-mL sample titrated with HCl requires 11.23 mL of 0.0983 M HCl to reach the end point. Calculate K_{sp} for $\text{Ca}(\text{OH})_2$. Compare your result with that in Appendix D. Do you think the solution was kept at 25°C ?
- 17.114** The osmotic pressure of a saturated solution of strontium sulfate at 25°C is 21 torr . What is the solubility product of this salt at 25°C ?
- 17.115** A concentration of $10\text{--}100$ parts per billion (by mass) of Ag^+ is an effective disinfectant in swimming pools. However, if the concentration exceeds this range, the Ag^+ can cause adverse health effects. One way to maintain an appropriate concentration of Ag^+ is to add a slightly soluble salt to the pool. Using K_{sp} values from Appendix D, calculate the equilibrium concentration of Ag^+ in parts per billion that would exist in equilibrium with (a) AgCl , (b) AgBr , (c) AgI .
- [17.116]** Fluoridation of drinking water is employed in many places to aid in the prevention of tooth decay. Typically the F^- ion concentration is adjusted to about 1 ppb . Some water supplies are also "hard"; that is, they contain certain cations such as Ca^{2+} that interfere with the action of soap. Consider a case where the concentration of Ca^{2+} is 8 ppb . Could a precipitate of CaF_2 form under these conditions? (Make any necessary approximations.)

WHAT'S AHEAD

18.1 EARTH'S ATMOSPHERE

We begin with a look at the temperature profile, pressure profile, and chemical composition of Earth's atmosphere. We then examine *photoionization* and *photodissociation*, reactions that result from atmospheric absorption of solar radiation.

18.2 HUMAN ACTIVITIES AND EARTH'S ATMOSPHERE

We next examine the effect human activities have on the atmosphere. We discuss how atmospheric ozone is depleted by

reactions involving human-made gases and how acid rain and smog are the result of atmospheric reactions involving compounds produced by human activity.

18.3 EARTH'S WATER

We examine the global water cycle, which describes how water moves from the ground to surface water to the atmosphere and back into the ground. We compare the chemical compositions of *seawater*, *freshwater*, and *groundwater*.

THE BIG ISLAND of Hawaii.

18.4 HUMAN ACTIVITIES AND EARTH'S WATER

We consider how Earth's water is connected to the global climate and examine one measure of water quality: dissolved oxygen concentration. Water for drinking and for irrigation must be free of salts and pollutants.

18.5 GREEN CHEMISTRY

We conclude by examining *green chemistry*, an international initiative to make industrial products, processes, and chemical reactions compatible with a sustainable society and environment.

CHEMISTRY OF THE ENVIRONMENT

THE RICHNESS OF LIFE ON Earth, represented in the chapter-opening photograph, is, as far as we know, unique. Earth's atmosphere, the energy received from the Sun, and the abundance of water on our planet are all features currently believed to be necessary for life.

As technology has advanced and the world human population has increased, humans have put new and greater stresses on the environment. Paradoxically, the very technology that can cause pollution also provides the tools to help understand and manage the environment in a beneficial way. Chemistry is often at the heart of environmental issues. The economic growth of both developed and developing nations depends critically on chemical processes that range from treatment of water supplies to industrial processes. Some of these processes produce products or by-products that are harmful to the environment.

We are now in a position to apply the principles we have learned in preceding chapters to an understanding of how our environment operates and how human activities affect it. To understand and protect the environment in which we live, we must understand how human-made and natural chemical compounds interact on land and in the sea and sky. Our daily decisions as consumers mirror those of leading experts and governmental leaders: In making each decision, we must weigh the costs versus the benefits of our actions. Unfortunately, the environmental impacts of our decisions are often subtle and not immediately evident.

18.1 EARTH'S ATMOSPHERE

Because most of us have never been very far from Earth's surface, we often take for granted the many ways in which the atmosphere determines the environment in which we live. In this section we examine some of the important characteristics of our planet's atmosphere.

The temperature of the atmosphere varies with altitude (◀ **FIGURE 18.1**), and the atmosphere is divided into four regions based on this temperature profile. Just above the surface, in the **troposphere**, the temperature normally decreases with increasing altitude, reaching a minimum of about 215 K at about 10 km. Nearly all of us live our entire

lives in the troposphere. Howling winds and soft breezes, rain, and sunny skies—all that we normally think of as “weather”—occur in this region. Commercial jet aircraft typically fly about 10 km (33,000 ft) above Earth, an altitude that defines the upper limit of the troposphere, which we call the *tropopause*.

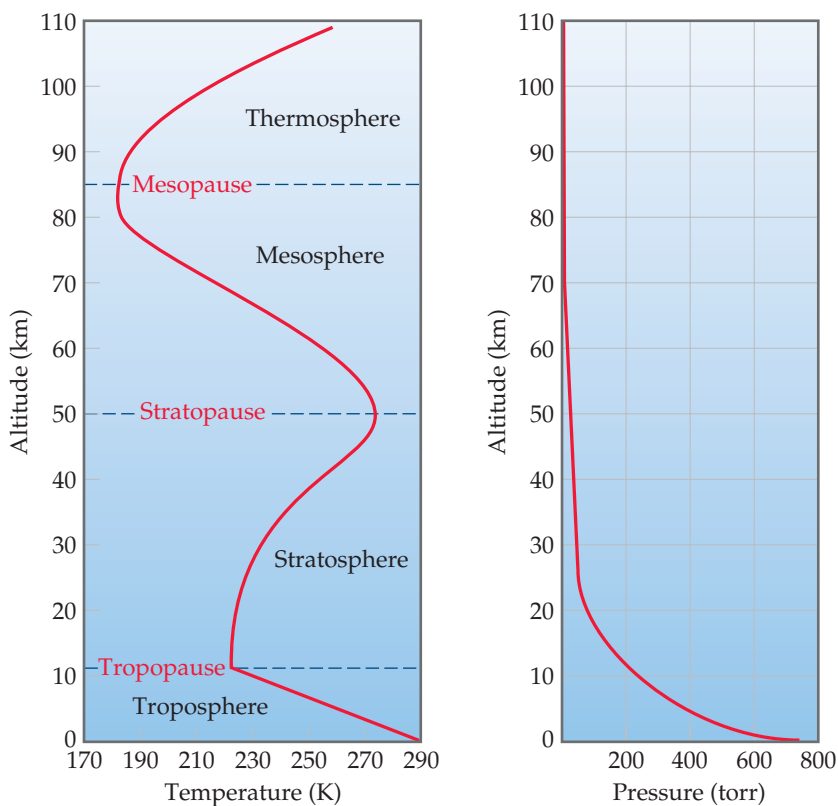

Above the tropopause, air temperature increases with altitude, reaching a maximum of about 275 K at about 50 km. The region from 10 km to 50 km is the **stratosphere**, and above it are the *mesosphere* and *thermosphere*. Notice in Figure 18.1 that the temperature extremes that form the boundaries between adjacent regions are denoted by the suffix *-pause*. The boundaries are important because gases mix across them relatively slowly. For example, pollutant gases generated in the troposphere pass through the tropopause and find their way into the stratosphere only very slowly.

Atmospheric pressure decreases with increasing elevation (Figure 18.1), declining much more rapidly at lower elevations than at higher ones because of the atmosphere's compressibility. Thus, the pressure decreases from an average value of 760 torr (101 kPa) at sea level to 2.3×10^{-3} torr (3.1×10^{-4} kPa) at 100 km, to only 1.0×10^{-6} torr (1.3×10^{-7} kPa) at 200 km.

The troposphere and stratosphere together account for 99.9% of the mass of the atmosphere, 75% of which is the mass in the troposphere. Consequently, most of the chemistry that follows focuses on these two regions.

GO FIGURE

At what altitude is the atmospheric temperature lowest?

▲ **FIGURE 18.1** Temperature and pressure in the atmosphere vary as a function of altitude above sea level.

Composition of the Atmosphere

Earth's atmosphere is constantly bombarded by radiation and energetic particles from the Sun. This barrage of energy has profound chemical and physical effects, especially in the upper regions of the atmosphere, above about 80 km (▶ **FIGURE 18.2**). In addition, because of Earth's gravitational field, heavier atoms and molecules tend to sink in the atmosphere, leaving lighter atoms and molecules at the top of the atmosphere. (This is why, as just noted, 75 percent of the atmosphere's mass is in the troposphere.) Because of all these factors, the composition of the atmosphere is not uniform.

▶ **TABLE 18.1** shows the composition of dry air near sea level. Note that although traces of many substances are present, N_2 and O_2 make up about 99% of sea-level air. The noble gases and CO_2 make up most of the remainder.

TABLE 18.1 • The Major Components of Dry Air Near Sea Level

Component*	Content (mole fraction)	Molar Mass (g/mol)
Nitrogen	0.78084	28.013
Oxygen	0.20948	31.998
Argon	0.00934	39.948
Carbon dioxide	0.000382	44.0099
Neon	0.00001818	20.183
Helium	0.00000524	4.003
Methane	0.000002	16.043
Krypton	0.00000114	83.80
Hydrogen	0.0000005	2.0159
Nitrous oxide	0.0000005	44.0128
Xenon	0.000000087	131.30

*Ozone, sulfur dioxide, nitrogen dioxide, ammonia, and carbon monoxide are present as trace gases in variable amounts.

When applied to substances in aqueous solution, the concentration unit *parts per million* refers to grams of substance per million grams of solution. ∞ (Section 13.4) When dealing with gases, however, 1 ppm means one part by *volume* in 1 million volumes of the whole. Because volume is proportional to number of moles of gas via the ideal-gas equation ($PV = nRT$), volume fraction and mole fraction are the same. Thus, 1 ppm of a trace constituent of the atmosphere amounts to 1 mol of that constituent in 1 million moles of air; that is, the concentration in parts per million is equal to the mole fraction times 10^6 . For example, Table 18.1 lists the mole fraction of CO_2 in the atmosphere as 0.000382, which means its concentration in parts per million is $0.000382 \times 10^6 = 382$ ppm.

Other minor constituents of the troposphere, in addition to CO_2 , are listed in ▼ **TABLE 18.2**.

Before we consider the chemical processes that occur in the atmosphere, let's review some of the properties of the two major components, N_2 and O_2 . Recall that the N_2 molecule possesses a triple bond between the nitrogen atoms. ∞ (Section 8.3) This very strong bond (bond energy 941 kJ/mol) is largely responsible for the very low reactivity of N_2 . The bond energy in O_2 is only 495 kJ/mol, making O_2 much more reactive than N_2 . For example, oxygen reacts with many substances to form oxides. The oxides of nonmetals, such as SO_2 , usually form acidic solutions when dissolved in water. The oxides of active metals, such as CaO , form basic solutions when dissolved in water. ∞ (Section 7.7)

▲ **FIGURE 18.2** The aurora borealis (northern lights).

TABLE 18.2 • Sources and Typical Concentrations of Some Minor Atmospheric Constituents

Constituent	Sources	Typical Concentration
Carbon dioxide, CO_2	Decomposition of organic matter, release from oceans, fossil-fuel combustion	382 ppm throughout troposphere
Carbon monoxide, CO	Decomposition of organic matter, industrial processes, fossil-fuel combustion	0.05 ppm in unpolluted air; 1–50 ppm in urban areas
Methane, CH_4	Decomposition of organic matter, natural-gas seepage, livestock emissions	1.77 ppm throughout troposphere
Nitric oxide, NO	Atmospheric electrical discharges, internal combustion engines, combustion of organic matter	0.01 ppm in unpolluted air; 0.2 ppm in smog
Ozone, O_3	Atmospheric electrical discharges, diffusion from the stratosphere, photochemical smog	0 to 0.01 ppm in unpolluted air; 0.5 ppm in photochemical smog
Sulfur dioxide, SO_2	Volcanic gases, forest fires, bacterial action, fossil-fuel combustion, industrial processes	0 to 0.01 ppm in unpolluted air; 0.1–2 ppm in polluted urban areas

SAMPLE EXERCISE 18.1 Calculating the Concentration of Water in Air

What is the concentration, in parts per million, of water vapor in a sample of air if the partial pressure of the water is 0.80 torr and the total pressure of the air is 735 torr?

SOLUTION

Analyze We are given the partial pressure of water vapor and the total pressure of an air sample and asked to determine the water vapor concentration.

Plan Recall that the partial pressure of a component in a mixture of gases is given by the product of its mole fraction and the total pressure of the mixture ∞ (Section 10.6):

$$P_{\text{H}_2\text{O}} = X_{\text{H}_2\text{O}}P_t$$

Solve Solving for the mole fraction of water vapor in the mixture, $X_{\text{H}_2\text{O}}$, gives

$$X_{\text{H}_2\text{O}} = \frac{P_{\text{H}_2\text{O}}}{P_t} = \frac{0.80 \text{ torr}}{735 \text{ torr}} = 0.0011$$

The concentration in ppm is the mole fraction times 10^6 :

$$0.0011 \times 10^6 = 1100 \text{ ppm}$$

PRACTICE EXERCISE

The concentration of CO in a sample of air is 4.3 ppm. What is the partial pressure of the CO if the total air pressure is 695 torr?

Answer: 3.0×10^{-3} torr

Photochemical Reactions in the Atmosphere

Although the atmosphere beyond the stratosphere contains only a small fraction of the atmospheric mass, it forms the outer defense against the hail of radiation and high-energy particles that continuously bombard Earth. As the bombarding radiation passes through the upper atmosphere, it causes two kinds of chemical changes: *photodissociation* and *photoionization*. These processes protect us from high-energy radiation by absorbing most of the radiation before it reaches the troposphere. If it were not for these photochemical processes, plant and animal life as we know it could not exist on Earth.

The Sun emits radiant energy over a wide range of wavelengths (▼ FIGURE 18.3). To understand the connection between the wavelength of radiation and its effect on

GO FIGURE

Why doesn't the solar spectrum at sea level perfectly match the solar spectrum outside the atmosphere?

► **FIGURE 18.3** The solar spectrum above Earth's atmosphere compared to that at sea level. The more structured curve at sea level is due to gases in the atmosphere absorbing specific wavelengths of light. "Flux," the unit on the vertical axis, is light energy per area per unit of time.

atoms and molecules, recall that electromagnetic radiation can be pictured as a stream of photons. ∞ (Section 6.2) The energy of each photon is given by $E = h\nu$, where h is Planck's constant and ν is the radiation frequency. For a chemical change to occur when radiation strikes atoms or molecules, two conditions must be met. First, the incoming photons must have sufficient energy to break a chemical bond or remove an electron from the atom or molecule. Second, the atoms or molecules being bombarded must absorb these photons. When these requirements are met, the energy of the photons is used to do the work associated with some chemical change.

The rupture of a chemical bond resulting from absorption of a photon by a molecule is called **photodissociation**. No ions are formed when the bond between two atoms is cleaved by photodissociation. Instead, half the bonding electrons stay with one atom and half stay with the other atom. The result is two electrically neutral particles.

One of the most important processes occurring above an altitude of about 120 km is photodissociation of the oxygen molecule:

The minimum energy required to cause this change is determined by the bond energy (or *dissociation energy*) of O_2 , 495 kJ/mol.

SAMPLE EXERCISE 18.2 Calculating the Wavelength Required to Break a Bond

What is the maximum wavelength of light, in nanometers, that has enough energy per photon to dissociate the O_2 molecule?

SOLUTION

Analyze We are asked to determine the wavelength of a photon that has just enough energy to break the $\text{O}=\text{O}$ double bond in O_2 .

Plan We first need to calculate the energy required to break the $\text{O}=\text{O}$ double bond in one molecule and then find the wavelength of a photon of this energy.

Solve The dissociation energy of O_2 is 495 kJ/mol. Using this value and Avogadro's number, we can calculate the amount of energy needed to break the bond in a single O_2 molecule:

$$\left(495 \times 10^3 \frac{\text{J}}{\text{mol}}\right) \left(\frac{1 \text{ mol}}{6.022 \times 10^{23} \text{ molecules}}\right) = 8.22 \times 10^{-19} \frac{\text{J}}{\text{molecule}}$$

We next use the Planck relationship, $E = h\nu$, ∞ (Equation 6.2) to calculate the frequency ν of a photon that has this amount of energy:

$$\nu = \frac{E}{h} = \frac{8.22 \times 10^{-19} \text{ J}}{6.626 \times 10^{-34} \text{ J}\cdot\text{s}} = 1.24 \times 10^{15} \text{ s}^{-1}$$

Finally, we use the relationship between frequency and wavelength ∞ (Section 6.1) to calculate the wavelength of the light:

$$\lambda = \frac{c}{\nu} = \left(\frac{3.00 \times 10^8 \text{ m/s}}{1.24 \times 10^{15} \text{ /s}}\right) \left(\frac{10^9 \text{ nm}}{1 \text{ m}}\right) = 242 \text{ nm}$$

Thus, light of wavelength 242 nm, which is in the ultraviolet region of the electromagnetic spectrum, has sufficient energy per photon to photodissociate an O_2 molecule. Because photon energy increases as wavelength *decreases*, any photon of wavelength *shorter* than 242 nm will have sufficient energy to dissociate O_2 .

PRACTICE EXERCISE

The bond energy in N_2 is 941 kJ/mol. What is the longest wavelength a photon can have and still have sufficient energy to dissociate N_2 ?

Answer: 127 nm

Fortunately for us, O_2 absorbs much of the high-energy, short-wavelength radiation from the solar spectrum before that radiation reaches the lower atmosphere. As it does, atomic oxygen, O , is formed. The dissociation of O_2 is very extensive at higher elevations. At 400 km, for example, only 1% of the oxygen is in the form of O_2 ; 99% is atomic oxygen. At 130 km, O_2 and atomic oxygen are just about equally abundant.

Below 130 km, O₂ is more abundant than atomic oxygen because most of the solar energy has been absorbed in the upper atmosphere.

The dissociation energy of N₂ is very high, 941 kJ/mol. Analogous to Practice Exercise 18.2, only photons having a wavelength shorter than 127 nm possess sufficient energy to dissociate N₂. Furthermore, N₂ does not readily absorb photons, even when they possess sufficient energy. As a result, very little atomic nitrogen is formed in the upper atmosphere by photodissociation of N₂.

Other photochemical processes besides photodissociation occur in the upper atmosphere, although their discovery has taken many twists and turns. In 1901 Guglielmo Marconi received a radio signal in St. John's, Newfoundland, that had been transmitted from Land's End, England, 2900 km away. Because people at the time thought radio waves traveled in straight lines, they assumed that the curvature of Earth's surface would make radio communication over large distances impossible. Marconi's successful experiment suggested that Earth's atmosphere in some way substantially affects radio-wave propagation. His discovery led to intensive study of the upper atmosphere. In about 1924, the existence of electrons in the upper atmosphere was established by experimental studies.

The electrons in the upper atmosphere result mainly from **photoionization**, which occurs when a molecule in the upper atmosphere absorbs solar radiation and the absorbed energy causes an electron to be ejected from the molecule. The molecule then becomes a positively charged ion. For photoionization to occur, therefore, a molecule must absorb a photon, and the photon must have enough energy to remove an electron. ∞ (Section 7.4)

Four important photoionization processes occurring in the atmosphere above about 90 km are shown in ▼ TABLE 18.3. Photons of any wavelength shorter than the maximum lengths given in the table have enough energy to cause photoionization. A look back at Figure 18.3, however, shows you that virtually all of these high-energy photons are filtered out of the radiation reaching Earth because they are absorbed by the upper atmosphere.

▲ GIVE IT SOME THOUGHT

Explain the difference between photoionization and photodissociation.

Ozone in the Stratosphere

Although N₂, O₂, and atomic oxygen absorb photons having wavelengths shorter than 240 nm, ozone, O₃, is the key absorber of photons having wavelengths ranging from 240 to 310 nm, in the ultraviolet region of the electromagnetic spectrum. Ozone in the upper atmosphere protects us from these harmful high-energy photons, which would otherwise penetrate to Earth's surface. Let's consider how ozone forms in the upper atmosphere and how it absorbs photons.

By the time radiation from the Sun reaches an altitude of 90 km above Earth's surface, most of the short-wavelength radiation capable of photoionization has been absorbed. At this altitude, however, radiation capable of dissociating the O₂ molecule is sufficiently intense for photodissociation of O₂ (Equation 18.1) to remain important down to an altitude of 30 km. In the region between 30 and 90 km, however, the concentration of

TABLE 18.3 • Photoionization Reactions for Four Components of the Atmosphere

Process	Ionization Energy (kJ/mol)	λ_{\max} (nm)
$\text{N}_2 + h\nu \longrightarrow \text{N}_2^+ + e^-$	1495	80.1
$\text{O}_2 + h\nu \longrightarrow \text{O}_2^+ + e^-$	1205	99.3
$\text{O} + h\nu \longrightarrow \text{O}^+ + e^-$	1313	91.2
$\text{NO} + h\nu \longrightarrow \text{NO}^+ + e^-$	890	134.5

O_2 is much greater than the concentration of atomic oxygen. From this finding, we conclude that the oxygen atoms formed by photodissociation of O_2 in this region frequently collide with O_2 molecules and form ozone:

The asterisk on O_3 denotes that the molecule contains an excess of energy. This reaction releases 105 kJ/mol. This energy must be transferred away from the O_3^* molecule quickly or else the molecule will fly apart into O_2 and atomic O—a decomposition that is the reverse of the reaction by which O_3^* is formed.

An energy-rich O_3^* molecule can release its excess energy by colliding with another atom or molecule and transferring some of the excess energy to it. Let's use M to represent the atom or molecule with which O_3^* collides. (Usually M is N_2 or O_2 because these are the most abundant molecules in the atmosphere.) The formation of O_3^* and the transfer of excess energy to M are summarized by the equations

The rate at which the reactions of Equations 18.3 and 18.4 proceed depends on two factors that vary in opposite directions with increasing altitude. First, the Equation 18.3 reaction depends on the presence of O atoms. At low altitudes, most of the radiation energetic enough to dissociate O_2 into O atoms has been absorbed; thus, O atoms are more plentiful at higher altitudes. Second, Equations 18.3 and 18.4 both depend on molecular collisions. ∞ (Section 14.5) The concentration of molecules is greater at low altitudes, and so the rates of both reactions are greater at lower altitudes. Because these two reactions vary with altitude in opposite directions, the highest rate of O_3 formation occurs in a band at an altitude of about 50 km, near the stratopause (Figure 18.1). Overall, roughly 90% of Earth's ozone is found in the stratosphere.

GIVE IT SOME THOUGHT

Why don't O_2 and N_2 molecules filter out ultraviolet light with wavelengths between 240 and 310 nm?

The photodissociation of ozone reverses the reaction that forms it. We thus have a cycle of ozone formation and decomposition, summarized as follows:

The first and third processes are photochemical; they use a solar photon to initiate a chemical reaction. The second and fourth are exothermic chemical reactions. The net result of the four reactions is a cycle in which solar radiant energy is converted into thermal energy. The ozone cycle in the stratosphere is responsible for the rise in temperature that reaches its maximum at the stratopause (Figure 18.1).

The reactions of the ozone cycle account for some, but not all, of the facts about the ozone layer. Many chemical reactions occur that involve substances other than oxygen. We must also consider the effects of turbulence and winds that mix up the stratosphere. A complicated picture results. The overall result of ozone formation and removal reactions, coupled with atmospheric turbulence and other factors, is to produce the upper-atmosphere ozone profile shown in **FIGURE 18.4**, with a maximum ozone concentration occurring at an altitude of about 25 km. This band of relatively high ozone concentration is referred to as the “ozone layer” or the “ozone shield.”

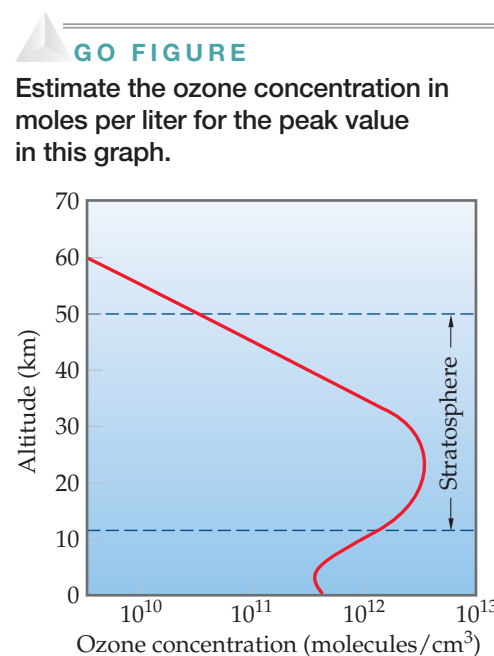

FIGURE 18.4 Variation in ozone concentration in the atmosphere as a function of altitude.

Photons with wavelengths shorter than about 300 nm are energetic enough to break many kinds of single chemical bonds. Thus, the “ozone shield” is essential for our continued well-being. The ozone molecules that form this essential shield against high-energy radiation represent only a tiny fraction of the oxygen atoms present in the stratosphere, however, because these molecules are continually destroyed even as they are formed.

▲ **FIGURE 18.5** Mount Pinatubo erupts, June 1991.

18.2 HUMAN ACTIVITIES AND EARTH'S ATMOSPHERE

Both natural and *anthropogenic* (human-caused) events can modify Earth's atmosphere. One impressive natural event was the eruption of Mount Pinatubo in June 1991 (▲ **FIGURE 18.5**). The volcano ejected approximately 10 km^3 of material into the stratosphere, causing a 10% drop in the amount of sunlight reaching Earth's surface during the next 2 years. That drop in sunlight led to a temporary $0.5 \text{ }^\circ\text{C}$ drop in Earth's surface temperature. The volcanic particles that made it to the stratosphere remained there for approximately 3 years, *raising* the temperature of the stratosphere by several degrees due to light absorption. Measurements of the stratospheric ozone concentration showed significantly increased ozone decomposition in this 3-year period.

Eruption of the Icelandic volcano Eyjafjallajökull in 2010, though not as large as the Pinatubo eruption, has similarly affected the atmosphere over large regions of the Northern Hemisphere.

The Ozone Layer and Its Depletion

The ozone layer protects Earth's surface from damaging ultraviolet (UV) radiation. Therefore, if the concentration of ozone in the stratosphere decreases substantially, more UV radiation will reach Earth's surface, causing unwanted photochemical reactions, including reactions correlated with skin cancer. Satellite monitoring of ozone, which began in 1978, has revealed a depletion of ozone in the stratosphere that is particularly severe over Antarctica, a phenomenon known as the *ozone hole* (▲ **FIGURE 18.6**). The first scientific paper on this phenomenon appeared in 1985, and the National Aeronautics and Space Administration (NASA) maintains an “Ozone Hole Watch” website with daily updates and data from 1999 to the present.

In 1995 the Nobel Prize in Chemistry was awarded to F. Sherwood Rowland, Mario Molina, and Paul Crutzen for their studies of ozone depletion. In 1970 Crutzen showed that naturally occurring nitrogen oxides catalytically destroy ozone. Rowland and Molina recognized in 1974 that chlorine from **chlorofluorocarbons** (CFCs) may deplete the ozone layer. These substances, principally CFCl_3 and CF_2Cl_2 , do not occur in nature and have been widely used as propellants in spray cans, as refrigerant and air-conditioner gases, and as foaming agents for plastics. They are virtually unreactive in the lower atmosphere. Furthermore, they are relatively insoluble in water and are therefore not removed from the atmosphere by rainfall or by dissolution in the oceans. Unfortunately, the lack of reactivity that makes them commercially useful also allows them to survive in the atmosphere and to diffuse into the stratosphere. It is estimated that several million tons of chlorofluorocarbons are now present in the atmosphere.

As CFCs diffuse into the stratosphere, they are exposed to high-energy radiation, which can cause photodissociation. Because $\text{C}-\text{Cl}$ bonds are considerably weaker than $\text{C}-\text{F}$ bonds, free chlorine atoms are formed readily in the presence of light with wavelengths in the range from 190 to 225 nm, as shown in this typical reaction:

Calculations suggest that chlorine atom formation occurs at the greatest rate at an altitude of about 30 km, the altitude at which ozone is at its highest concentration.

▲ **FIGURE 18.6** Ozone present in the Southern Hemisphere, Sept. 24, 2006. This data was taken from an orbiting satellite. This day had the lowest stratospheric ozone concentration yet recorded. One “Dobson unit” corresponds to 2.69×10^{16} ozone molecules in a 1 cm^2 column of atmosphere.

Atomic chlorine reacts rapidly with ozone to form chlorine monoxide and molecular oxygen:

This reaction follows a second-order rate law with a very large rate constant:

$$\text{Rate} = k[\text{Cl}][\text{O}_3] \quad k = 7.2 \times 10^9 \text{ M}^{-1} \text{ s}^{-1} \text{ at } 298 \text{ K} \quad [18.8]$$

Under certain conditions, the ClO generated in Equation 18.7 can react to regenerate free Cl atoms. One way that this can happen is by photodissociation of ClO:

The Cl atoms generated in Equations 18.6 and 18.9 can react with more O_3 , according to Equation 18.7. The result is a sequence of reactions that accomplishes the Cl-catalyzed decomposition of O_3 to O_2 :

The equation can be simplified by eliminating like species from each side to give

Because the rate of Equation 18.7 increases linearly with $[\text{Cl}]$, the rate at which ozone is destroyed increases as the quantity of Cl atoms increases. Thus, the greater the amount of CFCs that diffuse into the stratosphere, the faster the destruction of the ozone layer. Even though troposphere-to-stratosphere diffusion rates are slow, a thinning of the ozone layer over the South Pole has been observed, particularly during September and October (Figure 18.6).

GIVE IT SOME THOUGHT

Since the rate of ozone destruction depends on $[\text{Cl}]$, can Cl be considered a catalyst for the reaction of Equation 18.10?

Because of the environmental problems associated with CFCs, steps have been taken to limit their manufacture and use. A major step was the signing in 1987 of the Montreal Protocol on Substances That Deplete the Ozone Layer, in which participating nations agreed to reduce CFC production. More stringent limits were set in 1992, when representatives of approximately 100 nations agreed to ban the production and use of CFCs by 1996, with some exceptions for “essential uses.” Since then, the production of CFCs has indeed dropped precipitously, and the size of the ozone hole has leveled off. Nevertheless, because CFCs are unreactive and because they diffuse so slowly into the stratosphere, scientists estimate that ozone depletion will continue for many years to come. What substances have replaced CFCs? At this time, the main alternatives are hydrofluorocarbons, compounds in which C—H bonds replace the C—Cl bonds of CFCs. One such compound in current use is CH_2FCF_3 , known as HFC-134a.

There are no naturally occurring CFCs, but some natural sources contribute chlorine and bromine to the atmosphere, and, just like halogens from CFC, these naturally occurring Cl and Br atoms can participate in ozone-depleting reactions. The principal natural sources are methyl bromide and methyl chloride, which are emitted from the oceans. It is estimated that these molecules contribute less than a third of the total Cl and Br in the atmosphere; the remaining two-thirds is a result of human activities.

Volcanoes are a source of HCl, but generally the HCl they release reacts with water in the troposphere and does not make it to the upper atmosphere.

TABLE 18.4 • Median Concentrations of Atmospheric Pollutants in a Typical Urban Atmosphere

Pollutant	Concentration (ppm)
Carbon monoxide	10
Hydrocarbons	3
Sulfur dioxide	0.08
Nitrogen oxides	0.05
Total oxidants (ozone and others)	0.02

Sulfur Compounds and Acid Rain

Sulfur-containing compounds are present to some extent in the natural, unpolluted atmosphere. They originate in the bacterial decay of organic matter, in volcanic gases, and from other sources listed in Table 18.2. The amount of these compounds released into the atmosphere worldwide from natural sources is about 24×10^{12} g per year, less than the amount from human activities, about 79×10^{12} g per year (principally related to combustion of fuels).

Sulfur compounds, chiefly sulfur dioxide, SO_2 , are among the most unpleasant and harmful of the common pollutant gases. ◀ **TABLE 18.4** shows the concentrations of several pollutant gases in a *typical* urban environment (where by *typical* we mean one that is not particularly affected by smog). According to these data, the level of sulfur dioxide is 0.08 ppm or higher about half the time. This concentration is considerably lower than that of other pollutants, notably carbon monoxide. Nevertheless, SO_2 is regarded as the most serious health hazard among the pollutants shown, especially for people with respiratory difficulties.

Combustion of coal accounts for about 65% of the SO_2 released annually in the United States, and combustion of oil accounts for another 20%. The majority of this amount is from coal-burning electrical power plants, which generate about 50% of our electricity. The extent to which SO_2 emissions are a problem when coal is burned depends on the amount of sulfur in the coal. Because of concern about SO_2 pollution, low-sulfur coal is in greater demand and is thus more expensive. Much of the coal from east of the Mississippi is relatively high in sulfur content, up to 6% by mass. Much of the coal from the western states has a lower sulfur content, but also a lower heat content per unit mass, so the difference in sulfur content per unit of heat produced is not as large as is often assumed.

China, which gets 70 percent of its energy from coal, is the world's largest generator of SO_2 , producing about 22 million tons annually. As a result, that nation has a major problem with SO_2 pollution and has set targets to reduce emissions with some success. In 2010, the U.S. Environmental Protection Agency set new standards to reduce SO_2 emissions, the first change in nearly 40 years. The old standard of 140 parts per billion, measured over 24 hours, will be replaced by a standard of 75 parts per billion, measured over 1 hour.

Sulfur dioxide is harmful to both human health and property; furthermore, atmospheric SO_2 can be oxidized to SO_3 by several pathways (such as reaction with O_2 or O_3). When SO_3 dissolves in water, it produces sulfuric acid:

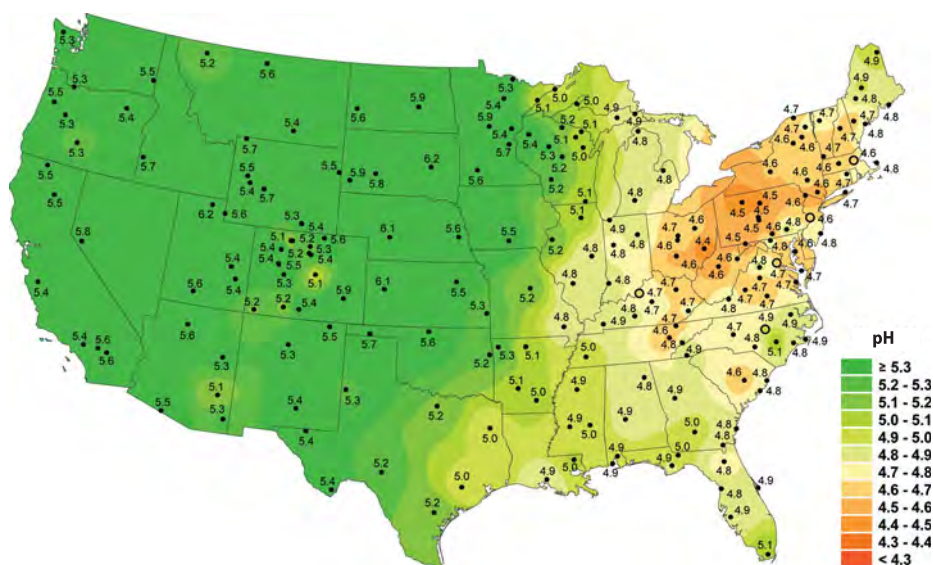

Many of the environmental effects ascribed to SO_2 are actually due to H_2SO_4 .

The presence of SO_2 in the atmosphere and the sulfuric acid it produces result in the phenomenon of **acid rain**. (Nitrogen oxides, which form nitric acid, are also major contributors to acid rain.) Uncontaminated rainwater generally has a pH value of about 5.6. The primary source of this natural acidity is CO_2 , which reacts with water to form carbonic acid, H_2CO_3 . Acid rain typically has a pH value of about 4. This acidity has affected many lakes in northern Europe, the northern United States, and Canada, reducing fish populations and affecting other parts of the ecological network in the lakes and surrounding forests.

The pH of most natural waters containing living organisms is between 6.5 and 8.5, but as ▶ **FIGURE 18.7** shows, freshwater pH values are far below 6.5 in many parts of the continental United States. At pH levels below 4.0, all vertebrates, most invertebrates, and many microorganisms are destroyed. The lakes most susceptible to damage are those with low concentrations of basic ions, such as HCO_3^- , that would act as a buffer to minimize changes in pH. Some of these lakes are recovering as sulfur emissions from fossil fuel combustion decrease, in part because of the Clean Air Act, which has resulted in a reduction of more than 40% in SO_2 emissions from power plants since 1980.

Because acids react with metals and with carbonates, acid rain is corrosive both to metals and to stone building materials. Marble and limestone, for example, whose major constituent is CaCO_3 , are readily attacked by acid rain (▶ **FIGURE 18.8**). Billions of dollars each year are lost because of corrosion due to SO_2 pollution.

One way to reduce the quantity of SO_2 released into the environment is to remove sulfur from coal and oil before these fuels are burned. Although difficult and expensive,

▲ FIGURE 18.7 Water pH values from freshwater sites across the United States, 2008. The numbered dots indicate the locations of monitoring stations.

(a)

(b)

▲ FIGURE 18.8 Damage from acid rain. The right photograph, recently taken, shows how the statue has lost detail in its carvings.

several methods have been developed. Powdered limestone (CaCO_3), for example, can be injected into the furnace of a power plant, where it decomposes into lime (CaO) and carbon dioxide:

The CaO then reacts with SO_2 to form calcium sulfite:

The solid particles of CaSO_3 , as well as much of the unreacted SO_2 , can be removed from the furnace gas by passing it through an aqueous suspension of CaO (► FIGURE 18.9). Not all the SO_2 is removed, however, and given the enormous quantities of coal and oil burned worldwide, pollution by SO_2 will probably remain a problem for some time.

▲ FIGURE 18.9 One method for removing SO_2 from combusted fuel.

▲ GIVE IT SOME THOUGHT

What chemical behavior associated with sulfur oxides gives rise to acid rain?

Nitrogen Oxides and Photochemical Smog

Nitrogen oxides are primary components of smog, a phenomenon with which city dwellers are all too familiar. The term *smog* refers to the pollution condition that occurs in certain urban environments when weather conditions produce a relatively stagnant air mass. The smog made famous by Los Angeles, but now common in many other urban areas as well, is more accurately described as **photochemical smog** because photochemical processes play a major role in its formation (◀ FIGURE 18.10).

The majority of nitrogen oxide emissions (about 50%) comes from cars, buses, and other forms of transportation. Nitric oxide, NO , forms in small quantities in the cylinders of internal combustion engines in the reaction

As noted in the “Chemistry Put to Work” box in Section 15.7, the equilibrium constant for this reaction increases from about 10^{-15} at 300 K to about 0.05 at 2400 K (approximate temperature in the cylinder of an engine during combustion). Thus, the reaction is more favorable at higher temperatures. In fact, some NO is formed in any high-temperature combustion. As a result, electrical power plants are also major contributors to nitrogen oxide pollution.

Before the installation of pollution-control devices on automobiles, typical emission levels of NO_x were 4 grams per mile. (The x is either 1 or 2 because both NO and NO_2 are formed, although NO predominates.) Starting in 2004, the auto emission standards for NO_x called for a phased-in reduction to 0.07 g/mi by 2009, which was achieved.

In air, nitric oxide is rapidly oxidized to nitrogen dioxide:

The equilibrium constant for this reaction decreases from about 10^{12} at 300 K to about 10^{-5} at 2400 K.

The photodissociation of NO_2 initiates the reactions associated with photochemical smog. Dissociation of NO_2 requires 304 kJ/mol, which corresponds to a photon wavelength of 393 nm. In sunlight, therefore, NO_2 dissociates to NO and O :

The atomic oxygen formed undergoes several reactions, one of which gives ozone, as described earlier:

▲ FIGURE 18.10 Photochemical smog is produced largely by the action of sunlight on vehicle exhaust gases.

Although it is an essential UV screen in the upper atmosphere, ozone is an undesirable pollutant in the troposphere. It is extremely reactive and toxic, and breathing air that contains appreciable amounts of ozone can be especially dangerous for asthma sufferers, exercisers, and the elderly. We therefore have two ozone problems: excessive amounts in many urban environments, where it is harmful, and depletion in the stratosphere, where its presence is vital.

In addition to nitrogen oxides and carbon monoxide, an automobile engine also emits unburned *hydrocarbons* as pollutants. These organic compounds are the principal components of gasoline and of many compounds we use as fuel (propane, C_3H_8 , and butane, C_4H_{10} ; for example), but are major ingredients of smog. A typical engine without effective emission controls emits about 10 to 15 g of hydrocarbons per mile. Current standards require that hydrocarbon emissions be less than 0.075 g per mile. Hydrocarbons are also emitted naturally from living organisms (see “A Closer Look” box later in this section).

Reduction or elimination of smog requires that the ingredients essential to its formation be removed from automobile exhaust. Catalytic converters reduce the levels of NO_x and hydrocarbons, two of the major ingredients of smog. (See the “Chemistry Put to Work: Catalytic Converters” in Section 14.7.)

GIVE IT SOME THOUGHT

What photochemical reaction involving nitrogen oxides initiates the formation of photochemical smog?

Greenhouse Gases: Water Vapor, Carbon Dioxide, and Climate

In addition to screening out harmful short-wavelength radiation, the atmosphere is essential in maintaining a reasonably uniform and moderate temperature on Earth's surface. Earth is in overall thermal balance with its surroundings. This means that the planet radiates energy into space at a rate equal to the rate at which it absorbs energy from the Sun.  **FIGURE 18.11** shows the distribution of radiation to and from Earth's

 **FIGURE 18.11 Earth's thermal balance.** The amount of radiation reaching the surface of the planet is approximately equal to the amount radiated back into space.

▲ **FIGURE 18.12** Portions of the infrared radiation emitted by Earth's surface that are absorbed by atmospheric CO_2 and H_2O .

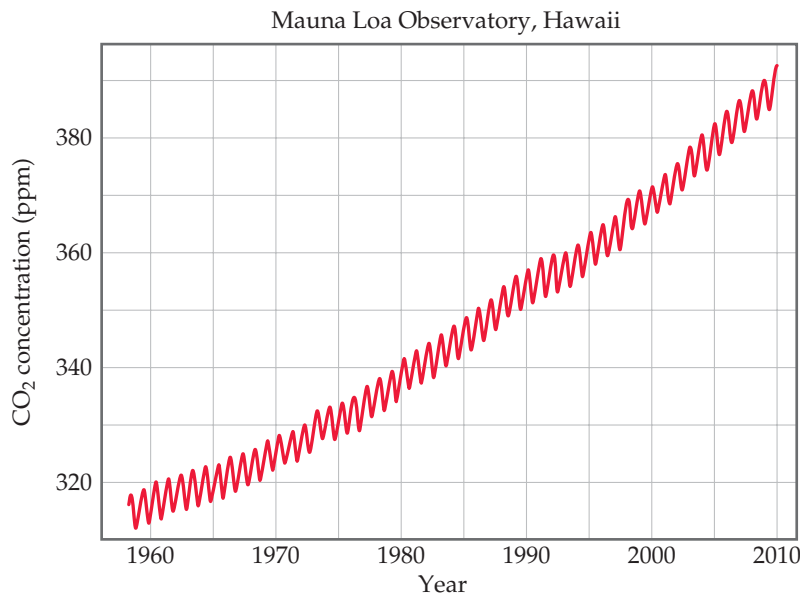

surface, and ▲ **FIGURE 18.12** shows which portion of the infrared radiation leaving the surface is absorbed by atmospheric water vapor and carbon dioxide. In absorbing this radiation, these two atmospheric gases help maintain a livable uniform temperature at the surface by holding in, as it were, the infrared radiation, which we feel as heat.

The influence of H_2O , CO_2 , and certain other atmospheric gases on Earth's temperature is called the *greenhouse effect* because in trapping infrared radiation these gases act much like the glass of a greenhouse. The gases themselves are called **greenhouse gases**.

Water vapor makes the largest contribution to the greenhouse effect. The partial pressure of water vapor in the atmosphere varies greatly from place to place and time to time but is generally highest near Earth's surface and drops off with increasing elevation. Because water vapor absorbs infrared radiation so strongly, it plays the major role in maintaining the atmospheric temperature at night, when the surface is emitting radiation into space and not receiving energy from the Sun. In very dry desert climates, where the water-vapor concentration is low, it may be extremely hot during the day but very cold at night. In the absence of a layer of water vapor to absorb and then radiate part of the infrared radiation back to Earth, the surface loses this radiation into space and cools off very rapidly.

Carbon dioxide plays a secondary but very important role in maintaining the surface temperature. The worldwide combustion of fossil fuels, principally coal and oil, on a prodigious scale in the modern era has sharply increased carbon dioxide levels in the atmosphere. To get a sense of the amount of CO_2 produced—for example, by the combustion of hydrocarbons and other carbon-containing substances, which are the components of fossil fuels—consider the combustion of butane, C_4H_{10} . Combustion of 1.00 g of C_4H_{10} produces 3.03 g of CO_2 . ∞ (Section 3.6) Similarly, a gallon (3.78 L) of gasoline (density 0.7 g/mL, approximate composition C_8H_{18}) produces about 8 kg of CO_2 . Combustion of fossil fuels releases about 2.2×10^{16} g (22 billion tons) of CO_2 into the atmosphere annually, with the largest quantity coming from transportation vehicles.

Much CO_2 is absorbed into oceans or used by plants. Nevertheless, we are now generating CO_2 much faster than it is being absorbed or used. Analysis of air trapped in ice cores taken from Antarctica and Greenland makes it possible to determine the

▲ FIGURE 18.13 Rising CO₂ levels. The sawtooth shape of the graph is due to regular seasonal variations in CO₂ concentration for each year.

atmospheric levels of CO₂ during the past 160,000 years. These measurements reveal that the level of CO₂ remained fairly constant from the last Ice Age, some 10,000 years ago, until roughly the beginning of the Industrial Revolution, about 300 years ago. Since that time, the concentration of CO₂ has increased by about 30% to a current high of about 386 ppm (▲ FIGURE 18.13).

A consensus is emerging among scientists that this increase in atmospheric CO₂ is perturbing Earth's climate and may be responsible for the observed increase in the average global air temperature of 0.3 °C to 0.6 °C over the past century. Scientists often use the term *climate change* instead of *global warming* to refer to this effect because as the Earth's temperature increases, it affects winds and ocean currents in ways that can cool some areas and warm others.

On the basis of present and expected future rates of fossil-fuel use, the atmospheric CO₂ level is expected to double from its present level sometime between 2050 and 2100. Computer models predict that this increase will result in an average global temperature increase of 1 °C to 3 °C. Because so many factors go into determining climate, we cannot predict with certainty what changes will occur because of this warming. Clearly, however, humanity has acquired the potential, by changing the concentrations of CO₂ and other heat-trapping gases in the atmosphere, to substantially alter the climate of the planet.

The climate change threat posed by atmospheric CO₂ has sparked considerable research into ways of capturing the gas at its largest combustion sources and storing it under ground or under the seafloor. There is also much interest in developing new ways to use CO₂ as a chemical feedstock. However, the approximately 115 million tons of CO₂ used annually by the global chemical industry is but a small fraction of the approximately 24 billion tons of annual CO₂ emissions. The use of CO₂ as a raw material will probably never be great enough to reduce its atmospheric concentration.

▲ GIVE IT SOME THOUGHT

Explain why nighttime temperatures remain higher in locations where there is higher humidity.

A CLOSER LOOK

OTHER GREENHOUSE GASES

Although CO_2 receives most of the attention, other gases contribute to the greenhouse effect, including methane, CH_4 , hydrofluorocarbons (HFCs), and chlorofluorocarbons (CFCs).

HFCs have replaced CFCs in a host of applications, including refrigerants and air-conditioner gases. Although they do not contribute to the depletion of the ozone layer, HFCs are nevertheless strong greenhouse gases. Their total concentration in the atmosphere is still small (40 parts per trillion), but this amount is increasing about 10% per year. Thus, these substances are becoming increasingly important contributors to the greenhouse effect.

Methane already makes a significant contribution to the greenhouse effect. Each methane molecule has about 25 times the greenhouse effect of a CO_2 molecule. Studies of atmospheric gas trapped long ago in the Greenland and Antarctic ice sheets show that the atmospheric methane concentration has increased from pre-industrial values of 0.3 to 0.7 ppm to the present value of about 1.8 ppm. The major sources of methane are associated with agriculture and fossil-fuel use.

Methane is formed in biological processes that occur in low-oxygen environments. Anaerobic bacteria, which flourish in swamps and landfills, near the roots of rice plants, and in the digestive systems of cows and other ruminant animals, produce methane (► **FIGURE 18.14**). It also leaks into the atmosphere during natural-gas extraction and transport. It is estimated that about two-thirds of present-day methane emissions, which are increasing by about 1% per year, are related to human activities.

Methane has a half-life in the atmosphere of about 10 years, whereas CO_2 is much longer-lived. This might seem a good thing, but there are indirect effects to consider. Methane is oxidized in the stratosphere, producing water vapor, a powerful greenhouse gas that is otherwise virtually absent from the stratosphere. In the troposphere, methane is attacked by reactive species such as OH radicals or nitrogen oxides, eventually producing other greenhouse gases, such as O_3 . It has been estimated that the climate-changing effects of CH_4 are more than half those of CO_2 . Given this large contribution, important reductions of the greenhouse effect could be achieved by reducing methane emissions or capturing the emissions for use as a fuel.

▲ **FIGURE 18.14** Methane production. Ruminant animals, such as cows and sheep, produce methane in their digestive systems.

18.3 EARTH'S WATER

Water covers 72% of Earth's surface and is essential to life. Our bodies are about 65% water by mass. Because of extensive hydrogen bonding, water has unusually high melting and boiling points and a high heat capacity. ∞ (Section 11.2) Water's highly polar character is responsible for its exceptional ability to dissolve a wide range of ionic and polar-covalent substances. Many reactions occur in water, including reactions in which H_2O itself is a reactant. Recall, for example, that H_2O can participate in acid–base reactions as either a proton donor or a proton acceptor. ∞ (Section 16.3) All these properties play a role in our environment.

The Global Water Cycle

All the water on Earth is connected in a global water cycle (► **FIGURE 18.15**). Most of the processes depicted here rely on the phase changes of water. For instance, warmed by the Sun, liquid water in the oceans evaporates into the atmosphere as water vapor and condenses into liquid water droplets that we see as clouds. Water droplets in the clouds can crystallize to ice, which can precipitate as hail or snow. Once on the ground, the hail or snow melts to liquid water, which soaks into the ground. If conditions are right, it is also possible for ice on the ground to sublime to water vapor in the atmosphere.

▲ GIVE IT SOME THOUGHT

Consider the phase diagram for water shown in Figure 11.28 (page 446). In what pressure range and in what temperature range must H_2O exist in order for $\text{H}_2\text{O}(s)$ to sublime to $\text{H}_2\text{O}(g)$?

◀ FIGURE 18.15 The global water cycle.

Salt Water: Earth's Oceans and Seas

The vast layer of salty water that covers so much of the planet is in actuality one large connected body and is generally constant in composition. For this reason, oceanographers speak of a *world ocean* rather than of the separate oceans we learn about in geography books.

The world ocean is huge, having a volume of $1.35 \times 10^9 \text{ km}^3$ and containing 97.2% of all the water on Earth. Of the remaining 2.8%, 2.1% is in the form of ice caps and glaciers. All the freshwater—in lakes, in rivers, and in the ground—amounts to only 0.6%. Most of the remaining 0.1% is in brackish (salty) water, such as that in the Great Salt Lake in Utah.

Seawater is often referred to as saline water. The **salinity** of seawater is the mass in grams of dry salts present in 1 kg of seawater. In the world ocean, salinity averages about 35. To put it another way, seawater contains about 3.5% dissolved salts by mass. The list of elements present in seawater is very long. Most, however, are present only in very low concentrations. ▼ TABLE 18.5 lists the 11 ionic species most abundant in seawater.

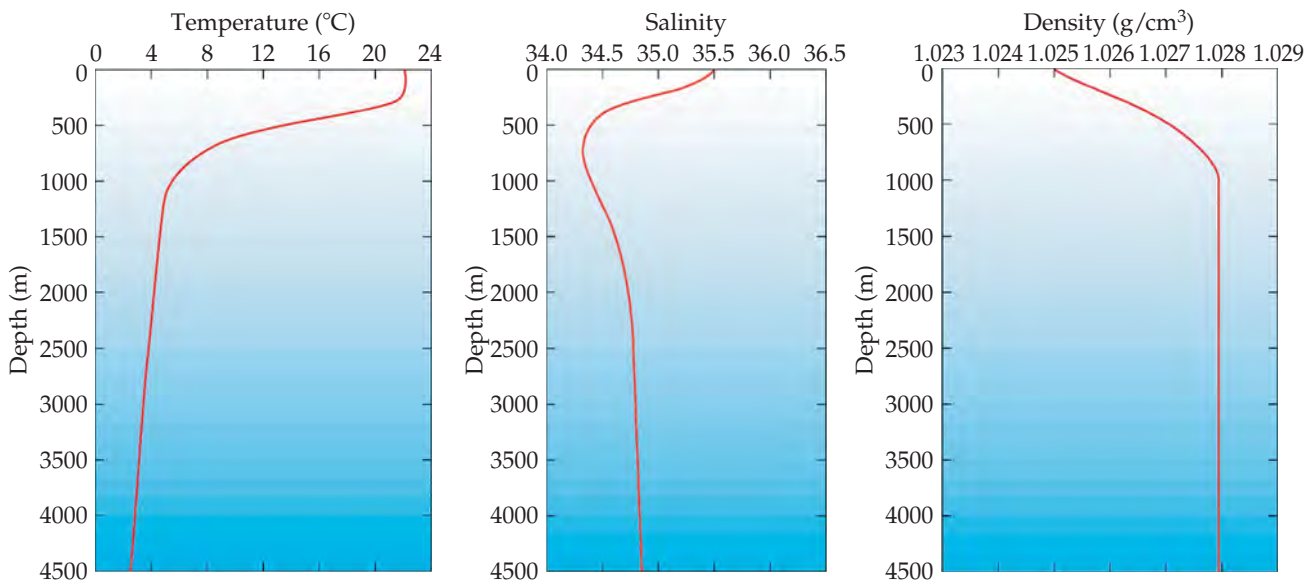

TABLE 18.5 • Ionic Constituents of Seawater Present in Concentrations Greater Than 0.001 g/kg (1 ppm)

Ionic Constituent	Salinity	Concentration (M)
Chloride, Cl^-	19.35	0.55
Sodium, Na^+	10.76	0.47
Sulfate, SO_4^{2-}	2.71	0.028
Magnesium, Mg^{2+}	1.29	0.054
Calcium, Ca^{2+}	0.412	0.010
Potassium, K^+	0.40	0.010
Carbon dioxide*	0.106	2.3×10^{-3}

* CO_2 is present in seawater as HCO_3^- and CO_3^{2-} .

GO FIGURE

Look at the trend in density as a function of depth; does it mirror the trend in salinity or in temperature?

▲ FIGURE 18.16 Average temperature, salinity, and density of seawater as a function of depth. (From *Windows to the Universe*, University Corporation for Atmospheric Research. Copyright © 2004 University Corporation for Atmospheric Research. All rights reserved.)

Seawater temperature, salinity, and density vary as a function of depth (▲ FIGURE 18.16). Sunlight penetrates well only 200 m into the water; the region between 200 m and 1000 m deep is the “twilight zone,” where visible light is faint. Below 1000 m, the ocean is pitch-black and cold, about 4 °C. The transport of heat, salt, and other chemicals throughout the ocean is influenced by these changes in the physical properties of seawater, and in turn the changes in the way heat and substances are transported affects ocean currents and the global climate.

The sea is so vast that if the concentration of a substance in seawater is 1 part per billion (1×10^{-6} g per kilogram of water), there is 1×10^{12} kg of the substance in the world ocean. Nevertheless, because of high extracting costs, only three substances are obtained from seawater in commercially important amounts: sodium chloride, bromine (from bromide salts), and magnesium (from its salts).

Absorption of CO_2 by the ocean plays a large role in global climate. Because carbon dioxide and water form carbonic acid, the H_2CO_3 concentration in the ocean increases as the water absorbs atmospheric CO_2 . Most of the carbon in the ocean, however, is in the form of HCO_3^- and CO_3^{2-} ions, which form a buffer system that maintains the ocean’s pH between 8.0 and 8.3. The pH of the ocean is predicted to decrease as the concentration of CO_2 in the atmosphere increases, as discussed in the “Chemistry and Life” box on ocean acidification in Section 17.5.

Freshwater and Groundwater

Freshwater is the term used to denote natural waters that have low concentrations (less than 500 ppm) of dissolved salts and solids. Freshwater includes the waters of lakes, rivers, ponds, and streams. The United States is fortunate in its abundance of freshwater— 1.7×10^{15} L (660 trillion gallons) is the estimated reserve, which is renewed by rainfall. An estimated 9×10^{11} L of freshwater is used every day in the United States. Most of this is used for agriculture (41%) and hydroelectric power (39%), with small amounts for industry (6%), household needs (6%), and drinking water (1%). An adult drinks about 2 L of water per day. In the United States, our daily use of

GO FIGURE

What factors influence how long it takes for water to migrate from a deep aquifer to the surface?

◀ **FIGURE 18.17** Groundwater is water located in aquifers below the soil. An unconfined aquifer, that has no dense rock between it and the water table, can hold water for days or years. Confined aquifers can hold water for centuries or millennia, depending on their depth. Aquifers are discharged through wells or rivers, and are recharged from water flowing through the soil (e.g., from rain).

water per person far exceeds this subsistence level, amounting to an average of about 300 L/day for personal consumption and hygiene. We use about 8 L/person for cooking and drinking, about 120 L/person for cleaning (bathing, laundering, and housecleaning), 80 L/person for flushing toilets, and 80 L/person for watering lawns.

The total amount of freshwater on Earth is not a very large fraction of the total water present. Indeed, freshwater is one of our most precious resources. It forms by evaporation from the oceans and the land. The water vapor that accumulates in the atmosphere is transported by global atmospheric circulation, eventually returning to Earth as rain, snow, and other forms of precipitation (Figure 18.15).

As water runs off the land on its way to the oceans, it dissolves a variety of cations (mainly Na^+ , K^+ , Mg^{2+} , Ca^{2+} , and Fe^{2+}), anions (mainly Cl^- , SO_4^{2-} , and HCO_3^-), and gases (principally O_2 , N_2 , and CO_2). As we use water, it becomes laden with additional dissolved material, including the wastes of human society. As our population and output of environmental pollutants increase, we find that we must spend ever-increasing amounts of money and resources to guarantee a supply of freshwater.

Approximately 20% of the world's freshwater is under the soil, in the form of *groundwater*. Groundwater resides in *aquifers*, which are layers of porous rock that hold water. The water in aquifers can be very pure and accessible for human consumption if near the surface (▲ FIGURE 18.17). Dense rock that does not allow water to readily penetrate can hold groundwater for years or even millennia.

The nature of the rock that contains the groundwater has a large influence on the water's chemical composition. If minerals in the rock are water soluble to some extent, ions can leach out of the rock and remain dissolved in the groundwater. Arsenic in the form of HAsO_4^{2-} , H_2AsO_4^- , and H_3AsO_3 are found in groundwater across the world, most infamously in Bangladesh, at concentrations poisonous to humans.

18.4 HUMAN ACTIVITIES AND EARTH'S WATER

All life on Earth depends on the availability of suitable water. Some organisms can thrive under temperature, pH, and ionic conditions where other organisms would die. Many human activities rely on waste disposal via Earth's waters, even today, and this practice can be detrimental to aquatic organisms.

▲ **FIGURE 18.18 Eutrophication.** This rapid accumulation of dead and decaying plant matter in a body of water uses up the water's oxygen supply, making the water unsuitable for aquatic animals.

GO FIGURE

What feature of this process is responsible for its being called *reverse osmosis*?

▲ **FIGURE 18.19 Reverse osmosis.**

Dissolved Oxygen and Water Quality

The amount of O_2 dissolved in water is an important indicator of water quality. Water fully saturated with air at 1 atm and 20 °C contains about 9 ppm of O_2 . Oxygen is necessary for fish and most other aquatic life. Cold-water fish require water containing at least 5 ppm of dissolved oxygen for survival. Aerobic bacteria consume dissolved oxygen to oxidize organic materials for energy. The organic material the bacteria are able to oxidize is said to be **biodegradable**.

Excessive quantities of biodegradable organic materials in water are detrimental because they remove the oxygen necessary to sustain normal animal life. Typical sources of these biodegradable materials, which are called *oxygen-demanding wastes*, include sewage, industrial wastes from food-processing plants and paper mills, and liquid waste from meatpacking plants.

In the presence of oxygen, the carbon, hydrogen, nitrogen, sulfur, and phosphorus in biodegradable material end up mainly as CO_2 , HCO_3^- , H_2O , NO_3^- , SO_4^{2-} , and phosphates. The formation of these oxidation products sometimes reduces the amount of dissolved oxygen to the point where aerobic bacteria can no longer survive. Anaerobic bacteria then take over the decomposition process, forming CH_4 , NH_3 , H_2S , PH_3 , and other products, several of which contribute to the offensive odors of some polluted waters.

Plant nutrients, particularly nitrogen and phosphorus, contribute to water pollution by stimulating excessive growth of aquatic plants. The most visible results of excessive plant growth are floating algae and murky water. What is more significant, however, is that as plant growth becomes excessive, the amount of dead and decaying plant matter increases rapidly, a process called *eutrophication* (◀ **FIGURE 18.18**). The processes by which plants decay consumes O_2 , and without sufficient oxygen, the water cannot sustain animal life.

The most significant sources of nitrogen and phosphorus compounds in water are domestic sewage (phosphate-containing detergents and nitrogen-containing body wastes), runoff from agricultural land (fertilizers contain both nitrogen and phosphorus), and runoff from livestock areas (animal wastes contain nitrogen).

GIVE IT SOME THOUGHT

If a test on a sample of polluted water shows a considerable decrease in dissolved oxygen over a five-day period, what can we conclude about the nature of the pollutants present?

Water Purification: Desalination

Because of its high salt content, seawater is unfit for human consumption and for most of the uses to which we put water. In the United States the salt content of municipal water supplies is restricted by health codes to no more than about 0.05% by mass. This amount is much lower than the 3.5% dissolved salts present in seawater and the 0.5% or so present in brackish water found underground in some regions. The removal of salts from seawater or brackish water to make the water usable is called **desalination**.

Water can be separated from dissolved salts by *distillation* because water is a volatile substance and the salts are nonvolatile. ∞ (Section 13.5: "A Closer Look: Ideal Solutions with Two or More Volatile Components") The principle of distillation is simple enough, but carrying out the process on a large scale presents many problems. As water is distilled from seawater, for example, the salts become more and more concentrated and eventually precipitate out. Distillation is also an energy-intensive process.

Seawater can also be desalinated using **reverse osmosis**. Recall that osmosis is the net movement of solvent molecules, but not solute molecules, through a semipermeable membrane. ∞ (Section 13.5) In osmosis, the solvent passes from the more dilute solution into the more concentrated one. However, if sufficient external pressure is applied, osmosis can be stopped and, at still higher pressures, reversed. When reverse osmosis occurs, solvent passes from the more concentrated into the more dilute solution. In a modern reverse-osmosis facility, hollow fibers are used as the semipermeable membrane (◀ **FIGURE 18.19**). Water is introduced under pressure into the fibers, and desalinated water is recovered.

▲ FIGURE 18.20 Common steps in treating water for a public water system.

The world's largest desalination plant, in Jubail, Saudi Arabia, provides 50% of that country's drinking water by using reverse osmosis to desalinate seawater from the Persian Gulf. Such plants are becoming increasingly common in the United States. The largest, near Tampa Bay, Florida, has been operating since 2007 and produces 35 million gallons of drinking water a day by reverse osmosis. Small-scale, manually operated reverse-osmosis desalinators are used in camping, traveling, and at sea.

Water Purification: Municipal Treatment

The water needed for domestic, agricultural, and industrial use is taken either from lakes, rivers, and underground sources or from reservoirs. Much of the water that finds its way into municipal water systems is “used” water, meaning it has already passed through one or more sewage systems or industrial plants. Consequently, this water must be treated before it is distributed to our faucets.

Municipal water treatment usually involves five steps (▲ FIGURE 18.20). After coarse filtration through a screen, the water is allowed to stand in large sedimentation tanks where sand and other minute particles settle out. To aid in removing very small particles, the water may first be made slightly basic with CaO. Then $\text{Al}_2(\text{SO}_4)_3$ is added and reacts with OH^- ions to form a spongy, gelatinous precipitate of $\text{Al}(\text{OH})_3$ ($K_{sp} = 1.3 \times 10^{-33}$). This precipitate settles slowly, carrying suspended particles down with it, thereby removing nearly all finely divided matter and most bacteria. The water is then filtered through a sand bed. Following filtration, the water may be sprayed into the air (aeration) to hasten oxidation of dissolved organic substances.

The final step normally involves treating the water with a chemical agent to ensure the destruction of bacteria. Ozone is more effective, but chlorine is less expensive. Liquefied Cl_2 is dispensed from tanks through a metering device directly into the water supply. The amount used depends on the presence of other substances with which the chlorine might react and on the concentrations of bacteria and viruses to be removed. The sterilizing action of chlorine is probably due not to Cl_2 itself but to hypochlorous acid, which forms when chlorine reacts with water:

As many as a billion people worldwide lack access to clean water. According to the United Nations, 95% of the world's cities still dump raw sewage into their water supplies. Thus, it should come as no surprise that 80% of all the health maladies in developing countries can be traced to waterborne diseases associated with unsanitary water.

One promising development is a device called the LifeStraw (► FIGURE 18.21). When a person sucks water through the straw, the water first encounters a textile filter

▲ FIGURE 18.21 A LifeStraw purifies water as it is drunk.

A CLOSER LOOK

WATER SOFTENING

Water containing a relatively high concentration of Ca^{2+} , Mg^{2+} , and other divalent cations is called *hard water*. Although the presence of these ions is generally not a health threat, they can make water unsuitable for some household and industrial uses. For example, these ions react with soap to form an insoluble soap scum, the stuff of bathtub rings.

In addition, mineral deposits may form when water containing these ions is heated. When water containing calcium ions and bicarbonate ions is heated, some carbon dioxide is driven off. As a result, the solution becomes less acidic and insoluble calcium carbonate forms:

The solid CaCO_3 coats the surface of hot-water systems and teakettles, reducing heating efficiency (▼ FIGURE 18.22). These deposits, called *scale*, can be especially serious in boilers where water is heated under pressure in pipes running through a furnace.

▲ FIGURE 18.22 Scale formation. The interior of this water pipe has been coated with CaCO_3 and other insoluble salts deposited from hard water.

Removal of the ions that cause hard water is called *water softening*. In the *lime-soda process* used for large-scale municipal water-softening operations, the water is treated with calcium hydroxide (prepared from lime) and, sodium carbonate (sometimes called soda ash) to precipitate Ca^{2+} as CaCO_3 and Mg^{2+} as $\text{Mg}(\text{OH})_2$:

In *ion exchange*, a typical household method for softening water, hard water is passed through an ion-exchange resin made up of plastic beads with covalently bound anion groups such as $-\text{COO}^{-}$ or $-\text{SO}_3^{-}$. These negatively charged groups have Na^{+} ions to balance their charges. The Ca^{2+} and other cations in the hard water are attracted to the anionic groups and displace the lower-charged Na^{+} into the water. Thus, one type of ion is exchanged for another. To maintain charge balance, 2Na^{+} enter the water for each Ca^{2+} removed. If we represent the resin with its anionic site as $\text{R}-\text{COO}^{-}$, we can write the equation for the process as

Water softened in this way contains an increased concentration of Na^{+} . Although Na^{+} does not form precipitates or cause other problems associated with hard-water cations, individuals concerned about their sodium intake, such as those who have high blood pressure (hypertension), should avoid drinking water softened in this way.

When all the available Na^{+} ions have been displaced from the ion-exchange resin, the resin is regenerated by flushing it with a concentrated solution of NaCl . The high concentration of Na^{+} forces the equilibrium in the preceding equation to shift to the left, causing the Na^{+} to displace the hard-water cations, which are flushed down the drain.

with a mesh opening of $100\ \mu\text{m}$ followed by a second textile filter with a mesh opening of $15\ \mu\text{m}$. These filters remove debris and even clusters of bacteria. The water next encounters a chamber of iodine-impregnated beads, where bacteria, viruses, and parasites are killed. Finally, the water passes through granulated active carbon, which removes the smell of iodine as well as the parasites that have not been taken by the filters or killed by the iodine.

Water disinfection is one of the greatest public health innovations in human history. It has dramatically decreased the incidences of waterborne bacterial diseases such as cholera and typhus. However, this great benefit comes at a price.

In 1974 scientists in Europe and the United States discovered that chlorination of water produces a group of by-products previously undetected. These by-products are called *trihalomethanes* (THMs) because all have a single carbon atom and three halogen atoms: CHCl_3 , CHCl_2Br , CHClBr_2 , and CHBr_3 . These and many other chlorine- and bromine-containing organic substances are produced by the reaction of dissolved chlorine with the organic materials present in nearly all natural waters, as well as with

substances that are by-products of human activity. Recall that chlorine dissolves in water to form the oxidizing agent HClO:

The HClO in turn reacts with organic substances to form THMs. Bromine enters the reaction sequence through the reaction of HClO with dissolved bromide ion:

Then both HBrO(aq) and HClO(aq) can halogenate organic substances to form the THMs.

Some THMs and other halogenated organic substances are suspected carcinogens; others interfere with the body's endocrine system. As a result, the World Health Organization and the U.S. Environmental Protection Agency have placed concentration limits of $80 \mu\text{g}/\text{L}$ (80 ppb) on the total quantity of THMs in drinking water. The goal is to reduce the levels of THMs and other disinfection by-products in the drinking water supply while preserving the antibacterial effectiveness of the water treatment. In some cases, lowering the concentration of chlorine may provide adequate disinfection while reducing the concentrations of THMs formed. Alternative oxidizing agents, such as ozone or chlorine dioxide, produce less of the halogenated substances but have their own disadvantages. For example, each is capable of oxidizing dissolved bromide, as shown here for ozone:

Bromate ion, BrO_3^- , has been shown to cause cancer in animal tests. Bromate's cancer-causing potential has led Los Angeles, for example, to add 3 million black plastic balls to one of its drinking water reservoirs to prevent bromate from forming via photochemical processes (► **FIGURE 18.23**).

At present, there seem to be no completely satisfactory alternatives to chlorination or ozonation, and we are faced with a consideration of benefit versus risk. In this case, the risks of cancer from THMs and related substances in municipal water are very low relative to the risks of cholera, typhus, and gastrointestinal disorders from untreated water. When the water supply is cleaner to begin with, less disinfectant is needed and thus the risk of THMs is lowered. Once THMs form, their concentrations in the water supply can be reduced by aeration because the THMs are more volatile than water. Alternatively, they can be removed by adsorption onto activated charcoal or other adsorbents.

▲ **FIGURE 18.23** Preventing photochemical bromate reactions. The black plastic balls added to this Los Angeles drinking water reservoir keep sunlight from entering the water and initiating reactions that form harmful bromate ions.

18.5 GREEN CHEMISTRY

The planet on which we live is, to a large extent, a *closed system*, one that exchanges energy but not matter with its environment. If humankind is to thrive in the future, all the processes we carry out should be in balance with Earth's natural processes and physical resources. This goal requires that no toxic materials be released to the environment, that our needs be met with renewable resources, and that we consume the least possible amount of energy. Although the chemical industry is but a small part of human activity, chemical processes are involved in nearly all aspects of modern life. Chemistry is therefore at the heart of efforts to accomplish these goals.

Green chemistry is an initiative that promotes the design and application of chemical products and processes that are compatible with human health and that preserve the environment. The founders of the initiative have developed a set of 12 principles to guide work in this area:

- 1. Prevention** It is better to prevent waste than to clean it up after it has been created.
- 2. Atom Economy** Methods to make chemical compounds should be designed to maximize the incorporation of all starting atoms into the final product.

3. **Less Hazardous Chemical Syntheses** Wherever practical, synthetic methods should be designed to use and generate substances that possess little or no toxicity to human health and the environment.
4. **Design of Safer Chemicals** Chemical products should be designed to minimize toxicity and yet maintain their desired function.
5. **Safer Solvents and Auxiliaries** The use of auxiliary substances (e.g., solvents, separation agents, etc.) should be eliminated wherever possible and, if used, should be as nontoxic as possible.
6. **Design for Energy Efficiency** Energy requirements of chemical processes should be recognized for their environmental and economic impacts and should be minimized. If possible, chemical reactions should be conducted at room temperature and pressure.
7. **Use of Renewable Feedstocks** A raw material or feedstock should be renewable whenever technically and economically practical.
8. **Reduction of Derivatives** Unnecessary derivatization (intermediate compound formation, temporary modification of physical/chemical processes) should be minimized or avoided if possible, because such steps require additional reagents and can generate waste.
9. **Catalysis** Catalytic reagents (as selective as possible) improve product yields within a given time and with a lower energy cost compared to noncatalytic processes and are, therefore, preferred to noncatalytic alternatives.
10. **Design for Degradation** Chemical products should be designed so that at the end of their function they break down into innocuous degradation products and do not persist in the environment.
11. **Real-Time Analysis for Pollution Prevention** Analytical methods need to be developed that allow for real-time, in-process monitoring and control prior to the formation of hazardous substances.
12. **Inherently Safer Chemistry for Accident Prevention** Reagents and solvents used in a chemical process should be chosen to minimize the potential for chemical accidents, including releases, explosions, and fires.*

GIVE IT SOME THOUGHT

Explain how a chemical reaction that uses a catalyst is “greener” than the same reaction run without a catalyst.

To illustrate how green chemistry works, consider the manufacture of styrene, an important building block for many polymers, including the expanded polystyrene packages used to pack eggs and restaurant takeout food. The global demand for styrene is more than 25 million metric tons per year. For many years, styrene has been produced in a two-step process: Benzene and ethylene react to form ethyl benzene, followed by the ethyl benzene being mixed with high-temperature steam and passed over an iron oxide catalyst to form styrene:

This process has several shortcomings. One is that both benzene, which is formed from crude oil, and ethylene, formed from natural gas, are high-priced starting materials for a product that should be a low-priced commodity, and another is that benzene is a known carcinogen. In a recently-developed process that bypasses some of

*Adapted from P. T. Anastas and J. C. Warner, *Green Chemistry: Theory and Practice*. New York: Oxford University Press 1998, p. 30.

these shortcomings, the two-step process is replaced by a one-step process in which toluene is reacted with methanol at 425 °C over a special catalyst:

The one-step process saves money both because toluene and methanol are less expensive than benzene and ethylene, and because the reaction requires less energy input. Additional benefits are that the methanol could be produced from biomass and that benzene is replaced by less-toxic toluene. The hydrogen formed in the reaction can be recycled as a source of energy. (This example demonstrates how finding the right catalyst is often key in discovering a new process.)

Let's consider some other examples in which green chemistry can operate to improve environmental quality.

Supercritical Solvents

A major area of concern in chemical processes is the use of volatile organic compounds as solvents. Generally, the solvent in which a reaction is run is not consumed in the reaction, and there are unavoidable releases of solvent into the atmosphere even in the most carefully controlled processes. Further, the solvent may be toxic or may decompose to some extent during the reaction, thus creating waste products.

The use of supercritical fluids represents a way to replace conventional solvents. Recall that a supercritical fluid is an unusual state of matter that has properties of both a gas and a liquid. ∞ (Section 11.4) Water and carbon dioxide are the two most popular choices as supercritical fluid solvents. One recently developed industrial process, for example, replaces chlorofluorocarbon solvents with liquid or supercritical CO₂ in the production of polytetrafluoroethylene ([CF₂CF₂]_n, sold as Teflon®). Though CO₂ is a greenhouse gas, no new CO₂ need be manufactured for use as a supercritical fluid solvent.

As a further example, *para*-xylene is oxidized to form terephthalic acid, which is used to make polyethylene terephthalate (PET) plastic and polyester fiber ∞ (Section 12.8, Table 12.5):

This commercial process requires pressurization and a relatively high temperature. Oxygen is the oxidizing agent, and acetic acid (CH₃COOH) is the solvent. An alternative route employs supercritical water as the solvent and hydrogen peroxide as the oxidant. This alternative process has several potential advantages, most particularly the elimination of acetic acid as solvent.

GIVE IT SOME THOUGHT

We noted earlier that increasing carbon dioxide levels contribute to global climate change, which seems like a bad thing, but now we are saying that using carbon dioxide in industrial processes is a good thing for the environment. Explain this seeming contradiction.

Greener Reagents and Processes

Let us examine two more examples of green chemistry in action.

Hydroquinone, HO-C₆H₄-OH, is a common intermediate used to make polymers. The standard industrial route to hydroquinone, used until recently, yields many by-products that are treated as waste:

Using the principles of green chemistry, researchers have improved this process. The new process for hydroquinone production uses a new starting material. Two of the by-products of the new reaction (shown in green) can be isolated and used to make the new starting material.

The new process is an example of “atom economy,” a phrase that means that a high percentage of the atoms from the starting materials end up in the product.

▲ GIVE IT SOME THOUGHT

What other reaction conditions could you change to make hydroquinone production even greener?

Another example of atom economy is a reaction in which, at room temperature and in the presence of a copper(I) catalyst, an organic *azide* and an *alkyne* form one product molecule:

This reaction is informally called a *click reaction*. The yield—actual, not just theoretical—is close to 100%, and there are no by-products. Depending on the type of azide and type of alkyne we start with, this very efficient click reaction can be used to create any number of valuable product molecules.

GIVE IT SOME THOUGHT

What are the hybridizations of the two alkyne C atoms before and after the click reaction?

SAMPLE INTEGRATIVE EXERCISE Putting Concepts Together

(a) Acid rain is no threat to lakes in areas where the rock is limestone (calcium carbonate), which can neutralize the acid. Where the rock is granite, however, no neutralization occurs. How does limestone neutralize acid? (b) Acidic water can be treated with basic substances to increase the pH, although such a procedure is usually only a temporary cure. Calculate the minimum mass of lime, CaO, needed to adjust the pH of a small lake ($V = 4 \times 10^9 \text{ L}$) from 5.0 to 6.5. Why might more lime be needed?

SOLUTION

Analyze We need to remember what a neutralization reaction is and calculate the amount of a substance needed to effect a certain change in pH.

Plan For (a), we need to think about how acid can react with calcium carbonate, a reaction that evidently does not happen with acid and granite. For (b), we need to think about what reaction between an acid and CaO is possible and do stoichiometric calculations. From the proposed change in pH, we can calculate the change in proton concentration needed and then figure out how much CaO is needed.

Solve

(a) The carbonate ion, which is the anion of a weak acid, is basic ∞ (Sections 16.2 and 16.7) and so reacts with $\text{H}^+(aq)$. If the concentration of $\text{H}^+(aq)$ is low, the major product is the bicarbonate ion, HCO_3^- . If the concentration of $\text{H}^+(aq)$ is high, H_2CO_3 forms and decomposes to CO_2 and H_2O . ∞ (Section 4.3)

(b) The initial and final concentrations of $\text{H}^+(aq)$ in the lake are obtained from their pH values:

$$[\text{H}^+]_{\text{initial}} = 10^{-5.0} = 1 \times 10^{-5} \text{ M} \quad \text{and} \quad [\text{H}^+]_{\text{final}} = 10^{-6.5} = 3 \times 10^{-7} \text{ M}$$

Using the lake volume, we can calculate the number of moles of $\text{H}^+(aq)$ at both pH values:

$$(1 \times 10^{-5} \text{ mol/L})(4.0 \times 10^9 \text{ L}) = 4 \times 10^4 \text{ mol}$$

$$(3 \times 10^{-7} \text{ mol/L})(4.0 \times 10^9 \text{ L}) = 1 \times 10^3 \text{ mol}$$

Hence, the change in the amount of $\text{H}^+(aq)$ is $4 \times 10^4 \text{ mol} - 1 \times 10^3 \text{ mol} \approx 4 \times 10^4 \text{ mol}$.

Let's assume that all the acid in the lake is completely ionized, so that only the free $\text{H}^+(aq)$ contributing to the pH needs to be neutralized. We need to neutralize at least that much acid, although there may be a great deal more than that amount in the lake.

The oxide ion of CaO is very basic. ∞ (Section 16.5) In the neutralization reaction, 1 mol of O^{2-} reacts with 2 mol of H^+ to form H_2O . Thus, $4 \times 10^4 \text{ mol}$ of H^+ requires

$$(4 \times 10^4 \text{ mol H}^+) \left(\frac{1 \text{ mol CaO}}{2 \text{ mol H}^+} \right) \left(\frac{56.1 \text{ g CaO}}{1 \text{ mol CaO}} \right) = 1 \times 10^6 \text{ g CaO}$$

This is slightly more than a ton of CaO. That would not be very costly because CaO is inexpensive, selling for less than \$100 per ton when purchased in large quantities. This amount of CaO is the minimum amount needed, however, because there are likely to be weak acids in the water that must also be neutralized.

This liming procedure has been used to bring the pH of some small lakes into the range necessary for fish to live. The lake in our example would be about a half mile long and a half mile wide and have an average depth of 20 ft.

CHAPTER SUMMARY AND KEY TERMS

SECTION 18.1 In this section we examined the physical and chemical properties of Earth's atmosphere. The complex temperature variations in the atmosphere give rise to four regions, each with characteristic properties. The lowest of these regions, the **troposphere**, extends from Earth's surface up to an altitude of about 12 km. Above the troposphere, in order of increasing altitude, are the **stratosphere**, mesosphere, and thermosphere. In the upper reaches of the atmosphere, only the simplest chemical species can survive the bombardment of highly energetic particles and radiation from the Sun. The average molecular weight of the atmosphere at high elevations is lower than that at Earth's surface because the lightest atoms and molecules diffuse upward and also because of **photodissociation**, which is the breaking of bonds in molecules because of the absorption of light. Absorption of radiation may also lead to the formation of ions via **photoionization**.

SECTION 18.2 Ozone is produced in the upper atmosphere from the reaction of atomic oxygen with O_2 . Ozone is itself decomposed by absorption of a photon or by reaction with an active species such as Cl. **Chlorofluorocarbons** can undergo photodissociation in the stratosphere, introducing atomic chlorine, which is capable of catalytically destroying ozone. A marked reduction in the ozone level in the upper atmosphere would have serious adverse consequences because the ozone layer filters out certain wavelengths of ultraviolet light that are not removed by any other atmospheric component. In the troposphere the chemistry of trace atmospheric components is of major importance. Many of these minor components are pollutants. Sulfur dioxide is one of the more noxious and prevalent examples. It is oxidized in air to form sulfur trioxide, which, upon dissolving in water, forms sulfuric acid. The oxides of sulfur are major contributors to **acid rain**. One method of preventing the escape of SO_2 from industrial operations is to react it with CaO to form calcium sulfite ($CaSO_3$).

Photochemical smog is a complex mixture in which both nitrogen oxides and ozone play important roles. Smog components are generated mainly in automobile engines, and smog control consists largely of controlling auto emissions.

Carbon dioxide and water vapor are the major components of the atmosphere that strongly absorb infrared radiation. CO_2 and H_2O are therefore critical in maintaining Earth's surface temperature. The concentrations of CO_2 and other so-called **greenhouse gases** in the atmosphere are thus important in determining worldwide climate. Because of the extensive combustion of fossil fuels (coal, oil, and natural

gas), the concentration of carbon dioxide in the atmosphere is steadily increasing.

SECTION 18.3 Earth's water is largely in the oceans and seas; only a small fraction is freshwater. Seawater contains about 3.5% by mass of dissolved salts and is described as having a **salinity** (grams of dry salts per 1 kg seawater) of 35. Seawater's density and salinity vary with depth. Because most of the world's water is in the oceans, humans may eventually need to recover freshwater from seawater. The global water cycle involves continuous phase changes of water.

SECTION 18.4 Freshwater contains many dissolved substances including dissolved oxygen, which is necessary for fish and other aquatic life. Substances that are decomposed by bacteria are said to be **biodegradable**. Because the oxidation of biodegradable substances by aerobic bacteria consumes dissolved oxygen, these substances are called oxygen-demanding wastes. The presence of an excess amount of oxygen-demanding wastes in water can sufficiently deplete the dissolved oxygen to kill fish and produce offensive odors. Plant nutrients can contribute to the problem by stimulating the growth of plants that become oxygen-demanding wastes when they die.

Desalination is the removal of dissolved salts from seawater or brackish water to make it fit for human consumption. Desalination may be accomplished by distillation or by **reverse osmosis**.

The water available from freshwater sources may require treatment before it can be used domestically. The several steps generally used in municipal water treatment include coarse filtration, sedimentation, sand filtration, aeration, sterilization, and sometimes water softening. Water softening is required when the water contains significant concentrations of ions such as Mg^{2+} and Ca^{2+} , which react with soap to form soap scum. Water containing such ions is called hard water. The lime-soda process, which involves adding CaO and Na_2CO_3 to hard water, is sometimes used for large-scale municipal water softening. Individual homes usually rely on ion exchange, a process by which hard-water ions are exchanged for Na^+ ions.

SECTION 18.5 The **green chemistry** initiative promotes the design and application of chemical products and processes that are compatible with human health and that preserve the environment. The areas in which the principles of green chemistry can operate to improve environmental quality include choices of solvents and reagents for chemical reactions, development of alternative processes, and improvements in existing systems and practices.

KEY SKILLS

- Describe the regions of Earth's atmosphere in terms of how temperature varies with altitude. (Section 18.1)
- Describe the composition of the atmosphere in terms of the major components in dry air at sea level. (Section 18.1)
- Calculate concentrations of gases in parts per million (ppm). (Section 18.1)
- Describe the processes of photodissociation and photoionization and their role in the upper atmosphere. (Section 18.1)
- Use bond energies and ionization energies to calculate the minimum frequency or maximum wavelength needed to cause photodissociation or photoionization. (Section 18.1)
- Explain the role of ozone in the upper atmosphere. (Section 18.1)
- Explain how chlorofluorocarbons (CFCs) are involved in depleting the ozone layer. (Section 18.2)
- Describe the origins and behavior of sulfur oxides and nitrogen oxides as air pollutants, including the generation of acid rain and photochemical smog. (Section 18.2)

- Describe how water and carbon dioxide in the atmosphere affect atmospheric temperature via the greenhouse effect. (Section 18.2)
- Describe the global water cycle. (Section 18.3)
- Explain what is meant by the salinity of water and describe the process of reverse osmosis as a means of desalination. (Section 18.4)
- List the major cations, anions, and gases present in natural waters and describe the relationship between dissolved oxygen and water quality. (Section 18.4)
- List the main steps involved in treating water for domestic uses. (Section 18.4)
- Describe the main goals of green chemistry. (Section 18.5)
- Be able to compare reactions and decide which reaction is greener. (Section 18.5)

EXERCISES

VISUALIZING CONCEPTS

- 18.1** At 273 K and 1 atm pressure, one mole of an ideal gas occupies 22.4 L. ∞ (Section 10.4) (a) Looking back at Figure 18.1, do you predict that 1 mole of an ideal gas in the middle of the stratosphere would occupy a greater or smaller volume than 22.4 L? (b) Looking at Figure 18.1, we see that the temperature is lower at 85 km altitude than at 50 km. Does this mean that one mole of an ideal gas would occupy less volume at 85 km than at 50 km? Explain. (c) In which parts of the atmosphere would you expect gases to behave most ideally (ignoring any photochemical reactions)? [Section 18.1]
- 18.2** Molecules in the upper atmosphere tend to contain double and triple bonds rather than single bonds. Suggest an explanation. [Section 18.1]
- 18.3** The figure shows the three lowest regions of Earth's atmosphere. (a) Name each and indicate the approximate elevations at which the boundaries occur. (b) In which region is ozone a pollutant? In which region does it filter UV solar radiation? (c) In which region is infrared radiation from Earth's surface most strongly reflected back? (d) An aurora borealis is due to excitation of atoms and molecules in the atmosphere 55–95 km above Earth's surface. Which regions in the figure are involved in an aurora borealis? (e) Compare the changes in relative concentrations of water vapor and carbon dioxide with increasing elevation in these three regions.

- 18.4** You are working with an artist who has been commissioned to make a sculpture for a big city in the eastern United States. The artist is wondering what material to use to make her sculpture

because she has heard that acid rain in the eastern United States might destroy it over time. You take samples of granite, marble, bronze, and other materials, and place them outdoors for a long time in the big city. You periodically examine the appearance and measure the mass of the samples. (a) What observations would lead you to conclude that one or more of the materials are well-suited for the sculpture? (b) What chemical process (or processes) is (are) the most likely responsible for any observed changes in the materials? [Section 18.2]

- 18.5** Where does the energy come from to evaporate the estimated 425,000 km³ of water that annually leaves the oceans? [Section 18.3]
- 18.6** Distinguish among salt water, freshwater, and groundwater. [Section 18.3]
- 18.7** How does carbon dioxide interact with the world ocean? [Section 18.3]
- 18.8** The following picture represents an ion-exchange column, in which water containing “hard” ions, such as Ca²⁺, is added to the top of the column, and water containing “soft” ions, such as Na⁺, comes out the bottom. Explain what is happening in the column. [Section 18.4]

- 18.9** Describe the basic goals of green chemistry. [Section 18.5]

18.10 One mystery in environmental science is the imbalance in the “carbon dioxide budget.” Considering only human activities, scientists have estimated that 1.6 billion metric tons of CO₂ is added to the atmosphere every year because of deforestation (plants use CO₂, and fewer plants will leave more CO₂ in the atmosphere). Another 5.5 billion tons per year is put into the atmosphere because of burning fossil fuels. It is further

estimated (again, considering only human activities) that the atmosphere actually takes up about 3.3 billion tons of this CO₂ per year, while the oceans take up 2 billion tons per year, leaving about 1.8 billion tons of CO₂ per year unaccounted for. This “missing” CO₂ is assumed to be taken up by the “land.” What do you think might be happening? [Sections 18.1–18.3]

EARTH'S ATMOSPHERE (section 18.1)

18.11 (a) What is the primary basis for the division of the atmosphere into different regions? (b) Name the regions of the atmosphere, indicating the altitude interval for each one.

18.12 (a) How are the boundaries between the regions of the atmosphere determined? (b) Explain why the stratosphere, which is more than 20 miles thick, has a smaller total mass than the troposphere, which is less than 10 miles thick.

18.13 Air pollution in the Mexico City metropolitan area is among the worst in the world. The concentration of ozone in Mexico City has been measured at 441 ppb (0.441 ppm). Mexico City sits at an altitude of 7400 feet, which means its atmospheric pressure is only 0.67 atm. (a) Calculate the partial pressure of ozone at 441 ppb if the atmospheric pressure is 0.67 atm. (b) How many ozone molecules are in 1.0 L of air in Mexico City? Assume $T = 25\text{ }^{\circ}\text{C}$.

18.14 From the data in Table 18.1, calculate the partial pressures of carbon dioxide and argon when the total atmospheric pressure is 1.05 bar.

18.15 The average concentration of carbon monoxide in air in an Ohio city in 2006 was 3.5 ppm. Calculate the number of CO molecules in 1.0 L of this air at a pressure of 759 torr and a temperature of 22 °C.

18.16 (a) From the data in Table 18.1, what is the concentration of neon in the atmosphere in ppm? (b) What is the concentration of neon in the atmosphere in molecules per L, assuming an atmospheric pressure of 730 torr and a temperature of 296 K?

18.17 The dissociation energy of a carbon–bromine bond is typically about 210 kJ/mol. (a) What is the maximum wavelength of photons that can cause C–Br bond dissociation? (b) Which kind of electromagnetic radiation—ultraviolet, visible, or infrared—does the wavelength you calculated in part (a) correspond to?

18.18 In CF₃Cl the C–Cl bond-dissociation energy is 339 kJ/mol. In CCl₄ the C–Cl bond-dissociation energy is 293 kJ/mol. What is the range of wavelengths of photons that can cause C–Cl bond rupture in one molecule but not in the other?

18.19 (a) Distinguish between *photodissociation* and *photoionization*. (b) Use the energy requirements of these two processes to explain why photodissociation of oxygen is more important than photoionization of oxygen at altitudes below about 90 km.

18.20 Why is the photodissociation of N₂ in the atmosphere relatively unimportant compared with the photodissociation of O₂?

HUMAN ACTIVITIES AND EARTH'S ATMOSPHERE (section 18.2)

18.21 Do the reactions involved in ozone depletion involve changes in oxidation state of the O atoms? Explain.

18.22 Explain how the reactions of ozone in the stratosphere are responsible for the relatively warm temperatures of the stratosphere.

18.23 (a) What is the difference between chlorofluorocarbons and hydrofluorocarbons? (b) Why are hydrofluorocarbons potentially less harmful to the ozone layer than CFCs?

18.24 Draw the Lewis structure for the chlorofluorocarbon CFC-11, CFCl₃. What chemical characteristics of this substance allow it to effectively deplete stratospheric ozone?

18.25 (a) Why is the fluorine present in chlorofluorocarbons not a major contributor to depletion of the ozone layer? (b) What are the chemical forms in which chlorine exists in the stratosphere following cleavage of the carbon–chlorine bond?

18.26 Would you expect the substance CBr₃ to be effective in depleting the ozone layer, assuming that it is present in the stratosphere? Explain.

18.27 For each of the following gases, make a list of known or possible naturally occurring sources: (a) CH₄, (b) SO₂, (c) NO.

18.28 Why is rainwater naturally acidic, even in the absence of polluting gases such as SO₂?

18.29 (a) Write a chemical equation that describes the attack of acid rain on limestone, CaCO₃. (b) If a limestone sculpture were treated to form a surface layer of calcium sulfate, would this help to slow down the effects of acid rain? Explain.

18.30 The first stage in corrosion of iron upon exposure to air is oxidation to Fe²⁺. (a) Write a balanced chemical equation to show the reaction of iron with oxygen and protons from acid rain. (b) Would you expect the same sort of reaction to occur with a silver surface? Explain.

18.31 Alcohol-based fuels for automobiles lead to the production of formaldehyde (CH₂O) in exhaust gases. Formaldehyde undergoes photodissociation, which contributes to photochemical smog:

The maximum wavelength of light that can cause this reaction is 335 nm. (a) In what part of the electromagnetic spectrum is light with this wavelength found? (b) What is the maximum strength of a bond, in kJ/mol, that can be broken by absorption of a photon of 335-nm light? (c) Compare your answer from part (b) to the appropriate value from Table 8.4. What do you conclude about C–H bond energy in formaldehyde? (d) Write out the formaldehyde photodissociation reaction, showing Lewis-dot structures.

- 18.32 An important reaction in the formation of photochemical smog is the photodissociation of NO_2 :

The maximum wavelength of light that can cause this reaction is 420 nm. (a) In what part of the electromagnetic spectrum is light with this wavelength found? (b) What is the maximum strength of a bond, in kJ/mol, that can be broken by absorption of a photon of 420-nm light? (c) Write out the photodissociation reaction showing Lewis-dot structures.

EARTH'S WATER (section 18.3)

- 18.35 What is the molarity of Na^+ in a solution of NaCl whose salinity is 5.6 if the solution has a density of 1.03 g/mol?
- 18.36 Phosphorus is present in seawater to the extent of 0.07 ppm by mass. If the phosphorus is present as phosphate, PO_4^{3-} , calculate the corresponding molar concentration of phosphate in seawater.
- 18.37 The enthalpy of evaporation of water is 40.67 kJ/mol. Sunlight striking Earth's surface supplies 168 W per square meter ($1 \text{ W} = 1 \text{ watt} = 1 \text{ J/s}$). (a) Assuming that evaporation of water is only due to energy input from the Sun, calculate how many grams of water could be evaporated from a 1.00 square meter patch of ocean over a 12-hour day. (b) The specific heat capacity of liquid water is 4.184 J/g $^\circ\text{C}$. If the initial temperature of a 1.00 square meter patch of ocean is 26 $^\circ\text{C}$, what is its final temperature after being in sunlight for 12 hours, assuming no phase changes and assuming that sunlight penetrates uniformly to depth of 10.0 cm?
- [18.38] The enthalpy of fusion of water is 6.01 kJ/mol. Sunlight striking Earth's surface supplies 168 W per square meter ($1 \text{ W} = 1 \text{ watt} = 1 \text{ J/s}$). (a) Assuming that melting of ice is only due to energy input from the Sun, calculate how many grams of ice could be melted from a 1.00 square meter patch of ice over a 12-hour day. (b) The specific heat capacity of ice is 2.032 J/g $^\circ\text{C}$. If the initial temperature of a 1.00 square meter patch of ice is $-5.0 \text{ }^\circ\text{C}$, what is its final temperature after being in sunlight for

12 hours, assuming no phase changes and assuming that sunlight penetrates uniformly to a depth of 1.00 cm?

- 18.39 A first-stage recovery of magnesium from seawater is precipitation of $\text{Mg}(\text{OH})_2$ with CaO :

What mass of CaO , in grams, is needed to precipitate 1000 lb of $\text{Mg}(\text{OH})_2$?

- 18.40 Gold is found in seawater at very low levels, about 0.05 ppb by mass. Assuming that gold is worth about \$800 per troy ounce, how many liters of seawater would you have to process to obtain \$1,000,000 worth of gold? Assume the density of seawater is 1.03 g/mL and that your gold recovery process is 50% efficient.
- 18.41 (a) What is *groundwater*? (b) What is an *aquifer*?
- 18.42 The Ogallala aquifer is the largest in the United States, covering 450,000 km^2 across eight states, from South Dakota to Texas. This aquifer provides 82% of the drinking water for the people who live in this region, although most ($>75\%$) of the water that is pumped from it is for irrigation. Irrigation withdrawals are approximately 18 billion gallons per day. (a) The Ogallala aquifer might run dry, according to some estimates, in 25 years. How many cubic kilometers of water would be withdrawn in a 25-year period? (b) Explain the processes that would recharge the aquifer.

HUMAN ACTIVITIES AND EARTH'S WATER (section 18.4)

- 18.43 Suppose that one wishes to use reverse osmosis to reduce the salt content of brackish water containing 0.22 M total salt concentration to a value of 0.01 M, thus rendering it usable for human consumption. What is the minimum pressure that needs to be applied in the permeators (Figure 18.19) to achieve this goal, assuming that the operation occurs at 298 K? (*Hint*: Refer to Section 13.5.)
- 18.44 Assume that a portable reverse-osmosis apparatus operates on seawater, whose concentrations of constituent ions are listed in Table 18.5, and that the desalinated water output has an effective molarity of about 0.02 M. What minimum pressure must be applied by hand pumping at 297 K to cause reverse osmosis to occur? (*Hint*: Refer to Section 13.5.)
- 18.45 List the common products formed when an organic material containing the elements carbon, hydrogen, oxygen, sulfur, and nitrogen decomposes (a) under aerobic conditions, (b) under anaerobic conditions.
- 18.46 (a) Explain why the concentration of dissolved oxygen in freshwater is an important indicator of the quality of the

water. (b) How is the solubility of oxygen in water affected by increasing temperature?

- 18.47 The organic anion

is found in most detergents. Assume that the anion undergoes aerobic decomposition in the following manner:

What is the total mass of O_2 required to biodegrade 10.0 g of this substance?

- 18.48 The average daily mass of O_2 taken up by sewage discharged in the United States is 59 g per person. How many liters of water at 9 ppm O_2 are totally depleted of oxygen in 1 day by a population of 1,200,000 people?

- 18.49** Write a balanced chemical equation to describe how magnesium ions are removed in water treatment by the addition of slaked lime, $\text{Ca}(\text{OH})_2$.
- 18.50** (a) Which of the following ionic species could be responsible for hardness in a water supply: Ca^{2+} , K^+ , Mg^{2+} , Fe^{2+} , Na^+ ? (b) What properties of an ion determine whether it will contribute to water hardness?
- 18.51** How many moles of $\text{Ca}(\text{OH})_2$ and Na_2CO_3 should be added to soften 1200 L of water in which $[\text{Ca}^{2+}] = 5.0 \times 10^{-4} \text{ M}$ and $[\text{HCO}_3^-] = 7.0 \times 10^{-4} \text{ M}$?
- 18.52** The concentration of Ca^{2+} in a particular water supply is $5.7 \times 10^{-3} \text{ M}$. The concentration of bicarbonate ion, HCO_3^- , in the same water is $1.7 \times 10^{-3} \text{ M}$. What masses of $\text{Ca}(\text{OH})_2$ and Na_2CO_3 must be added to $5.0 \times 10^7 \text{ L}$ of this water to reduce the level of Ca^{2+} to 20% of its original level?

- 18.53** Ferrous sulfate (FeSO_4) is often used as a coagulant in water purification. The iron(II) salt is dissolved in the water to be purified, then oxidized to the iron(III) state by dissolved oxygen, at which time gelatinous $\text{Fe}(\text{OH})_3$ forms, assuming the pH is above approximately 6. Write balanced chemical equations for the oxidation of Fe^{2+} to Fe^{3+} by dissolved oxygen and for the formation of $\text{Fe}(\text{OH})_3(\text{s})$ by reaction of $\text{Fe}^{3+}(\text{aq})$ with $\text{HCO}_3^-(\text{aq})$.
- 18.54** What properties make a substance a good coagulant for water purification?
- 18.55** (a) What are *trihalomethanes* (THMs)? (b) Draw the Lewis structures of two example THMs.
- 18.56** If trihalomethanes are easily removed from water by aeration (bubbling with air), what does this imply about the vapor pressure of THMs compared to water?

GREEN CHEMISTRY (section 18.5)

- 18.57** One of the principles of green chemistry is that it is better to use as few steps as possible in making new chemicals. How does this principle relate to energy efficiency?
- 18.58** Discuss how catalysts can make processes more energy efficient.
- 18.59** A reaction for converting ketones to lactones, called the Baeyer–Villiger reaction,

is used in the manufacture of plastics and pharmaceuticals. 3-Chloroperbenzoic acid is shock-sensitive, however, and prone to explode. Also, 3-chlorobenzoic acid is a waste product. An alternative process being developed uses hydrogen peroxide and a catalyst consisting of tin deposited within a solid support. The catalyst is readily recovered from the reaction mixture. (a) What would you expect to be the other product of oxidation of the ketone to lactone by hydrogen peroxide? (b) What principles of green chemistry are addressed by use of the proposed process?

- 18.60** The reaction shown here was performed with an iridium catalyst, both in supercritical CO_2 (scCO_2) and in the chlorinated solvent CH_2Cl_2 . The kinetic data for the reaction in both solvents are plotted in the graph. Why is this a good example of a green chemical reaction?

- 18.61** Which choice is greener in a chemical process? Explain. (a) Benzene as a solvent or water as a solvent. (b) The reaction temperature is 500 K, or 1000 K. (c) Sodium chloride as a by-product or chloroform (CHCl_3) as a by-product.
- 18.62** Which choice is greener in a chemical process? Explain. (a) A reaction that can be run at 350 K for 12 hours without a catalyst or one that can be run at 300 K for 1 hour with a catalyst. (b) A reagent for the reaction that can be obtained from corn husks or one that can be obtained from petroleum. (c) A process that produces no by-products or one in which the by-products are recycled for another process.

ADDITIONAL EXERCISES

- 18.63** A friend of yours has seen each of the following items in newspaper articles and would like an explanation: (a) acid rain, (b) greenhouse gas, (c) photochemical smog, (d) ozone depletion. Give a brief explanation of each term and identify one or two of the chemicals associated with each.
- 18.64** Suppose that on another planet the atmosphere consists of 17% Kr, 38% CH₄, and 45% O₂. What is the average molar mass at the surface? What is the average molar mass at an altitude at which all the O₂ is photodissociated?
- 18.65** If an average O₃ molecule “lives” only 100–200 seconds in the stratosphere before undergoing dissociation, how can O₃ offer any protection from ultraviolet radiation?
- 18.66** Show how Equations 18.7 and 18.9 can be added to give Equation 18.10.
- 18.67** What properties of CFCs make them ideal for various commercial applications but also make them a long-term problem in the stratosphere?
- 18.68** Halons are fluorocarbons that contain bromine, such as CBrF₃. They are used extensively as foaming agents for fighting fires. Like CFCs, halons are very unreactive and ultimately can diffuse into the stratosphere. (a) Based on the data in Table 8.4, would you expect photodissociation of Br atoms to occur in the stratosphere? (b) Propose a mechanism by which the presence of halons in the stratosphere could lead to the depletion of stratospheric ozone.
- 18.69** It is estimated that the lifetime for HFCs in the stratosphere is 2–7 years. If HFCs have such long lifetimes, why are they being used to replace CFCs?
- [18.70]** The *hydroxyl radical*, OH, is formed at low altitudes via the reaction of excited oxygen atoms with water:
- $$\text{O}^*(g) + \text{H}_2\text{O}(g) \longrightarrow 2\text{OH}(g)$$
- (a) Write the Lewis structure for the hydroxyl radical. (*Hint:* It has one unpaired electron.)
Once produced, the hydroxyl radical is very reactive. Explain why each of the following series of reactions affects the pollution in the troposphere:
- (b) $\text{OH} + \text{NO}_2 \longrightarrow \text{HNO}_3$
- (c) $\text{OH} + \text{CO} + \text{O}_2 \longrightarrow \text{CO}_2 + \text{OOH}$
 $\text{OOH} + \text{NO} \longrightarrow \text{OH} + \text{NO}_2$
- (d) $\text{OH} + \text{CH}_4 \longrightarrow \text{H}_2\text{O} + \text{CH}_3$
 $\text{CH}_3 + \text{O}_2 \longrightarrow \text{OOCH}_3$
 $\text{OOCH}_3 + \text{NO} \longrightarrow \text{OCH}_3 + \text{NO}_2$
- (e) The concentration of hydroxyl radicals in the troposphere is approximately 2×10^6 radicals per cm³. This estimate is based on a method called long path absorption spectroscopy (LPAS), similar in principle to the Beer’s law measurement discussed in the Closer Look essay on p. 564, except that the path length in the LPAS measurement is 20 km. Why must the path length be so large?
- 18.71** Explain, using Le Châtelier’s principle, why the equilibrium constant for the formation of NO from N₂ and O₂ increases with increasing temperature, whereas the equilibrium constant for the formation of NO₂ from NO and O₂ decreases with increasing temperature.
- 18.72** Natural gas consists primarily of methane, CH₄(g). (a) Write a balanced chemical equation for the complete combustion of methane to produce CO₂(g) as the only carbon-containing product. (b) Write a balanced chemical equation for the incomplete combustion of methane to produce CO(g) as the only carbon-containing product. (c) At 25 °C and 1.0 atm pressure, what is the minimum quantity of dry air needed to combust 1.0 L of CH₄(g) completely to CO₂(g)?
- 18.73** One of the possible consequences of climate change is an increase in the temperature of ocean water. The oceans serve as a “sink” for CO₂ by dissolving large amounts of it. (a) How would the solubility of CO₂ in the oceans be affected by an increase in the temperature of the water? (b) Discuss the implications of your answer to part (a) for the problem of climate change.
- 18.74** The rate of solar energy striking Earth averages 168 watts per square meter. The rate of energy radiated from Earth’s surface averages 390 watts per square meter. Comparing these numbers, one might expect that the planet would cool quickly, yet it does not. Why not?
- 18.75** The solar power striking Earth every day averages 168 watts per square meter. The peak electrical power usage in New York City is 12,000 megawatts. Considering that present technology for solar energy conversion is only about 10% efficient, from how many square meters of land must sunlight be collected in order to provide this peak power? (For comparison, the total area of the city is 830 km².)
- 18.76** Write balanced chemical equations for each of the following reactions: (a) The nitric oxide molecule undergoes photodissociation in the upper atmosphere. (b) The nitric oxide molecule undergoes photoionization in the upper atmosphere. (c) Nitric oxide undergoes oxidation by ozone in the stratosphere. (d) Nitrogen dioxide dissolves in water to form nitric acid and nitric oxide.
- 18.77** (a) Explain why Mg(OH)₂ precipitates when CO₃²⁻ ion is added to a solution containing Mg²⁺. (b) Will Mg(OH)₂ precipitate when 4.0 g of Na₂CO₃ is added to 1.00 L of a solution containing 125 ppm of Mg²⁺?
- [18.78]** It has been pointed out that there may be increased amounts of NO in the troposphere as compared with the past because of massive use of nitrogen-containing compounds in fertilizers. Assuming that NO can eventually diffuse into the stratosphere, how might it affect the conditions of life on Earth? Using the index to this text, look up the chemistry of nitrogen oxides. What chemical pathways might NO in the troposphere follow?
- [18.79]** As of the writing of this text, EPA standards limit atmospheric ozone levels in urban environments to 84 ppb. How many moles of ozone would there be in the air above Los Angeles County (area about 4000 square miles; consider a height of 10 m above the ground) if ozone was at this concentration?

INTEGRATIVE EXERCISES

18.80 The estimated average concentration of NO_2 in air in the United States in 2006 was 0.016 ppm. (a) Calculate the partial pressure of the NO_2 in a sample of this air when the atmospheric pressure is 755 torr (99.1 kPa). (b) How many molecules of NO_2 are present under these conditions at 20 °C in a room that measures $15 \times 14 \times 8$ ft?

[18.81] In 1986 an electrical power plant in Taylorsville, Georgia, burned 8,376,726 tons of coal, a national record at that time. (a) Assuming that the coal was 83% carbon and 2.5% sulfur and that combustion was complete, calculate the number of tons of carbon dioxide and sulfur dioxide produced by the plant during the year. (b) If 55% of the SO_2 could be removed by reaction with powdered CaO to form CaSO_3 , how many tons of CaSO_3 would be produced?

18.82 The water supply for a midwestern city contains the following impurities: coarse sand, finely divided particulates, nitrate ion, trihalomethanes, dissolved phosphorus in the form of phosphates, potentially harmful bacterial strains, dissolved organic substances. Which of the following processes or agents, if any, is effective in removing each of these impurities: coarse sand filtration, activated carbon filtration, aeration, ozonation, precipitation with aluminum hydroxide?

18.83 An impurity in water has an extinction coefficient of $3.45 \times 10^3 \text{ M}^{-1} \text{ cm}^{-1}$ at 280 nm, its absorption maximum (A Closer Look, p. 564). Below 50 ppb, the impurity is not a problem for human health. Given that most spectrometers cannot detect absorbances less than 0.0001 with good reliability, is measuring the absorbance of water at 280 nm a good way to detect concentrations of the impurity above the 50-ppb threshold?

18.84 The concentration of H_2O in the stratosphere is about 5 ppm. It undergoes photodissociation according to:

- Write out the Lewis-dot structures for both products and reactant.
- Using Table 8.4, calculate the wavelength required to cause this dissociation.
- The hydroxyl radicals, OH , can react with ozone, giving the following reactions:

What overall reaction results from these two elementary reactions? What is the catalyst in the overall reaction? Explain.

18.85 Bioremediation is the process by which bacteria repair their environment in response, for example, to an oil spill. The efficiency of bacteria for “eating” hydrocarbons depends on the amount of oxygen in the system, pH, temperature, and many other factors. In a certain oil spill, hydrocarbons from the oil disappeared with a first-order rate constant of $2 \times 10^{-6} \text{ s}^{-1}$. How many days did it take for the hydrocarbons to decrease to 10% of their initial value?

18.86 The standard enthalpies of formation of ClO and ClO_2 are 101 and 102 kJ/mol, respectively. Using these data and the thermodynamic data in Appendix C, calculate the overall enthalpy change for each step in the following catalytic cycle:

What is the enthalpy change for the overall reaction that results from these two steps?

18.87 The main reason that distillation is a costly method for purifying water is the high energy required to heat and vaporize water. (a) Using the density, specific heat, and heat of vaporization of water from Appendix B, calculate the amount of energy required to vaporize 1.00 gal of water beginning with water at 20 °C. (b) If the energy is provided by electricity costing \$0.085/kWh, calculate its cost. (c) If distilled water sells in a grocery store for \$1.26 per gal, what percentage of the sales price is represented by the cost of the energy?

[18.88] A reaction that contributes to the depletion of ozone in the stratosphere is the direct reaction of oxygen atoms with ozone:

At 298 K the rate constant for this reaction is $4.8 \times 10^5 \text{ M}^{-1} \text{ s}^{-1}$.

(a) Based on the units of the rate constant, write the likely rate law for this reaction. (b) Would you expect this reaction to occur via a single elementary process? Explain why or why not. (c) From the magnitude of the rate constant, would you expect the activation energy of this reaction to be large or small? Explain. (d) Use ΔH_f° values from Appendix C to estimate the enthalpy change for this reaction. Would this reaction raise or lower the temperature of the stratosphere?

18.89 Nitrogen dioxide (NO_2) is the only important gaseous species in the lower atmosphere that absorbs visible light. (a) Write the Lewis structure(s) for NO_2 . (b) How does this structure account for the fact that NO_2 dimerizes to form N_2O_4 ? Based on what you can find about this dimerization reaction in the text, would you expect to find the NO_2 that forms in an urban environment to be in the form of dimer? Explain. (c) What would you expect as products, if any, for the reaction of NO_2 with CO ? (d) Would you expect NO_2 generated in an urban environment to migrate to the stratosphere? Explain.

18.90 The following data were collected for the destruction of O_3 by H ($\text{O}_3 + \text{H} \longrightarrow \text{O}_2 + \text{OH}$) at very low concentrations:

Trial	$[\text{O}_3]$ (M)	$[\text{H}]$ (M)	Initial Rate (M/s)
1	5.17×10^{-33}	3.22×10^{-26}	1.88×10^{-14}
2	2.59×10^{-33}	3.25×10^{-26}	9.44×10^{-15}
3	5.19×10^{-33}	6.46×10^{-26}	3.77×10^{-14}

- Write the rate law for the reaction.
- Calculate the rate constant.

18.91 The degradation of $\text{CF}_3\text{CH}_2\text{F}$ (an HFC) by OH radicals in the troposphere is first order in each reactant and has a rate constant of $k = 1.6 \times 10^8 \text{ M}^{-1} \text{ s}^{-1}$ at 4 °C. If the tropospheric concentrations of OH and $\text{CF}_3\text{CH}_2\text{F}$ are 8.1×10^5 and 6.3×10^8 molecules/cm³, respectively, what is the rate of reaction at this temperature in M/s?

[18.92] The Henry's law constant for CO_2 in water at 25 °C is $3.1 \times 10^{-2} \text{ M atm}^{-1}$. (a) What is the solubility of CO_2 in water at this temperature if the solution is in contact with air at normal atmospheric pressure? (b) Assume that all of this CO_2 is in the form of H_2CO_3 produced by the reaction between CO_2 and H_2O :

What is the pH of this solution?

[18.93] If the pH of a 1.0-in. rainfall over 1500 mi² is 3.5, how many kilograms of H₂SO₄ are present, assuming that it is the only acid contributing to the pH?

18.94 The precipitation of Al(OH)₃ ($K_{sp} = 1.3 \times 10^{-33}$) is sometimes used to purify water. (a) Estimate the pH at which precipitation of Al(OH)₃ will begin if 5.0 lb of Al₂(SO₄)₃ is added to 2000 gal of water. (b) Approximately how many pounds of CaO must be added to the water to achieve this pH?

18.95 The valuable polymer polyurethane is made by a condensation reaction of alcohols (ROH) with compounds that contain an isocyanate group (RNCO). Two reactions that can generate a urethane monomer are shown here:

- (a) Which process, i or ii, is greener? Explain.
- (b) What are the hybridization and geometry of the carbon atoms in each C-containing compound in each reaction?
- (c) If you wanted to promote the formation of the isocyanate intermediate in each reaction, what could you do, using Le Châtelier's principle?

[18.96] The pH of a particular raindrop is 5.6. (a) Assuming the major species in the raindrop are H₂CO₃(aq), HCO₃⁻(aq), and CO₃²⁻(aq), calculate the concentrations of these species in the raindrop, assuming the total carbonate concentration is 1.0 × 10⁻⁵ M. The appropriate K_a values are given in Table 16.3. (b) What experiments could you do to test the hypothesis that the rain also contains sulfur-containing species that contribute to its pH? Assume you have a large sample of rain to test.

WHAT'S AHEAD

19.1 SPONTANEOUS PROCESSES

We see that changes that occur in nature have a directional character. They move *spontaneously* in one direction but not in the reverse direction.

19.2 ENTROPY AND THE SECOND LAW OF THERMODYNAMICS

We discuss *entropy*, a thermodynamic state function that is important in determining whether a process is spontaneous. The *second law of thermodynamics* tells us that in any spontaneous process the entropy of the universe (system plus surroundings) increases.

19.3 MOLECULAR INTERPRETATION OF ENTROPY

On the molecular level, the entropy of a system is related to the number of accessible *microstates*. The entropy of the system increases as the randomness of the system increases. The *third law of thermodynamics* states that, at 0 K, the entropy of a perfect crystalline solid is zero.

19.4 ENTROPY CHANGES IN CHEMICAL REACTIONS

Using tabulated *standard molar entropies*, we can calculate the standard entropy changes for systems undergoing reaction.

THE SKYLINE OF HONG KONG The construction of our human environment entails the use of enormous amounts of energy to create complex ordered structures, such as modern skyscrapers.

19.5 GIBBS FREE ENERGY

We encounter another thermodynamic state function, *free energy* (or *Gibbs free energy*), a measure of how far removed a system is from equilibrium. The change in free energy measures the maximum amount of useful work obtainable from a process and tells us the direction in which a chemical reaction is spontaneous.

19.6 FREE ENERGY AND TEMPERATURE

We consider how the relationship among free-energy change, enthalpy change, and entropy change provides insight into how temperature affects the spontaneity of a process.

19.7 FREE ENERGY AND THE EQUILIBRIUM CONSTANT

Finally, we consider how the standard free-energy change for a chemical reaction can be used to calculate the equilibrium constant for the reaction.

CHEMICAL THERMO- DYNAMICS

HUMANKIND HAS LEARNED TO HARNESS Earth's resources to create impressive, highly ordered structures, such as the beautiful skyline in the chapter-opening photograph. Our modern society depends heavily on the design of chemical reactions that produce specific useful substances from natural and synthetic materials.

Two of the most important questions chemists ask when designing and using chemical reactions are “How fast is the reaction?” and “How far does it proceed?” The first question is addressed by chemical kinetics, which we discussed in Chapter 14. The second question involves the equilibrium constant, the focus of Chapter 15. Let's briefly review how these concepts are related.

In Chapter 14 we learned that the rate of any chemical reaction is controlled largely by a factor related to energy, namely, the activation energy of the reaction. ∞ (Section 14.5) In general, the lower the activation energy, the faster a reaction proceeds. In Chapter 15 we saw that chemical equilibrium is reached when a given reaction and its reverse reaction occur at the same rate. ∞ (Section 15.1)

Because reaction rates are closely tied to energy, it is logical that equilibrium also depends in some way on energy. In this chapter we explore the connection between energy and the extent of a reaction. Doing so requires a deeper look at *chemical thermodynamics*, the area of chemistry that deals with energy relationships. We first encountered thermodynamics in Chapter 5, where we discussed the nature of energy,

the first law of thermodynamics, and the concept of enthalpy. Recall that the enthalpy change for any system is the heat transferred between the system and its surroundings during a constant-pressure process. [∞ \(Section 5.3\)](#)

In the “Strategies in Chemistry” box in Section 5.4, we pointed out that the enthalpy change that takes place during a reaction is an important guide as to whether the reaction is likely to proceed. Now we will see that reactions involve not only changes in enthalpy but also changes in *entropy*—another important thermodynamic quantity. Our discussion of entropy will lead us to the second law of thermodynamics, which provides insight into why physical and chemical changes tend to favor one direction over another. We drop a brick, for example, and it falls to the ground. We do not expect the brick to spontaneously rise from the ground to our outstretched hand. We light a candle, and it burns down. We do not expect a half-consumed candle to regenerate itself spontaneously, even if we have captured all the gases produced when the candle burned. Thermodynamics helps us understand the significance of this directional character of processes, regardless of whether they are exothermic or endothermic.

19.1 SPONTANEOUS PROCESSES

GO FIGURE
Does the potential energy of the eggs change during this process?

▲ FIGURE 19.1 A spontaneous process!

The first law of thermodynamics states that *energy is conserved*. [∞ \(Section 5.2\)](#) In other words, energy is neither created nor destroyed in any process, whether that process is a brick falling, a candle burning, or an ice cube melting. Energy can be transferred between a system and the surroundings and can be converted from one form to another, but the total energy of the universe remains constant. We expressed this law mathematically as $\Delta E = q + w$, where ΔE is the change in the internal energy of a system, q is the heat absorbed (or released) by the system from (or to) the surroundings, and w is the work done on the system by the surroundings, or on the surroundings by the system. Remember that $q > 0$ means that the system is absorbing heat from the surroundings, and $w > 0$ means that the surroundings are doing work on the system.

The first law helps us balance the books, so to speak, on the heat transferred between a system and its surroundings and the work done by or on a system. However, because energy is conserved, we can't simply use the value of ΔE to tell us whether a process is favored to occur because anything we do to lower the energy of the system raises the energy of the surroundings, and vice versa. Nevertheless, experience tells us that certain processes *always* occur, even though the energy of the universe is conserved. Water placed in a freezer turns into ice, for instance, and if you touch a hot object, heat is transferred to your hand. The first law guarantees that energy is conserved in these processes, and yet they occur without any outside intervention. We say they are *spontaneous*. A **spontaneous process** is one that proceeds on its own without any outside assistance.

A spontaneous process occurs in one direction only, and the reverse of any spontaneous process is always *nonspontaneous*. Drop an egg above a hard surface, for example, and it breaks on impact ([◀ FIGURE 19.1](#)). Now, imagine seeing a video clip in which a broken egg rises from the floor, reassembles itself, and ends up in someone's hand. You would conclude that the video is running in reverse because you know that broken eggs simply do not magically rise and reassemble themselves! An egg falling and breaking is spontaneous. The reverse process is *nonspontaneous*, even though energy is conserved in both processes.

We know other spontaneous and nonspontaneous processes that relate more directly to our study of chemistry. For example, a gas spontaneously expands into a vacuum ([▶ FIGURE 19.2](#)), but the reverse process, in which the gas moves back entirely into one of the flasks, does not happen. In other words, expansion of the gas is spontaneous, but the reverse process is nonspontaneous. In general, *processes that are spontaneous in one direction are nonspontaneous in the opposite direction*.

Experimental conditions, such as temperature and pressure, are often important in determining whether a process is spontaneous. We are all familiar with situations in which a forward process is spontaneous at one temperature but the reverse process is

spontaneous at a different temperature. Consider, for example, ice melting. At atmospheric pressure, when the temperature of the surroundings is above 0°C , ice melts spontaneously, and the reverse process—liquid water turning into ice—is not spontaneous. However, when the temperature of the surroundings is below 0°C , the opposite is true—liquid water turns to ice spontaneously, but the reverse process is *not* spontaneous (▼ FIGURE 19.3).

What happens at $T = 0^{\circ}\text{C}$, the normal melting point of water, when the flask of Figure 19.3 contains both water and ice? At the normal melting point of a substance, the solid and liquid phases are in equilibrium. ∞ (Section 11.6) At this temperature, the two phases are interconverting at the same rate and there is no preferred direction for the process.

It is important to realize that the fact that a process is spontaneous does not necessarily mean that it will occur at an observable rate. A chemical reaction is spontaneous if it occurs on its own accord, regardless of its speed. A spontaneous reaction can be very fast, as in the case of acid–base neutralization, or very slow, as in the rusting of iron. Thermodynamics tells us the *direction* and *extent* of a reaction but nothing about the *speed*.

GIVE IT SOME THOUGHT

If a process is nonspontaneous, does that mean the process cannot occur under any circumstances?

GO FIGURE

In which direction is this process exothermic?

▲ FIGURE 19.3 Spontaneity can depend on temperature. At $T > 0^{\circ}\text{C}$, ice melts spontaneously to liquid water. At $T < 0^{\circ}\text{C}$, the reverse process, water freezing to ice, is spontaneous. At $T = 0^{\circ}\text{C}$ the two states are in equilibrium.

SAMPLE EXERCISE 19.1 Identifying Spontaneous Processes

Predict whether each process is spontaneous as described, spontaneous in the reverse direction, or in equilibrium: (a) Water at 40°C gets hotter when a piece of metal heated to 150°C is added. (b) Water at room temperature decomposes into $\text{H}_2(\text{g})$ and $\text{O}_2(\text{g})$. (c) Benzene vapor, $\text{C}_6\text{H}_6(\text{g})$, at a pressure of 1 atm condenses to liquid benzene at the normal boiling point of benzene, 80.1°C .

SOLUTION

Analyze We are asked to judge whether each process is spontaneous in the direction indicated, in the reverse direction, or in neither direction.

Plan We need to think about whether each process is consistent with our experience about the natural direction of events or whether we expect the reverse process to occur.

Solve

(a) This process is spontaneous. Whenever two objects at different temperatures are brought into contact, heat is transferred from the hotter object to the colder one. ∞ (Section 5.1) Thus, heat is transferred from the hot metal to the cooler water. The final temperature, after the metal and water achieve the same temperature (thermal equilibrium), will be somewhere

GO FIGURE

If flask B were smaller than flask A, would the final pressure after the stopcock is opened be greater than, equal to, or less than 0.5 atm?

▲ FIGURE 19.2 Expansion of a gas into an evacuated space is a spontaneous process. The reverse process—gas molecules initially distributed evenly in two flasks all moving into one flask—is not spontaneous.

between the initial temperatures of the metal and the water. (b) Experience tells us that this process is not spontaneous—we certainly have never seen hydrogen and oxygen gases spontaneously bubbling up out of water! Rather, the *reverse* process—the reaction of H_2 and O_2 to form H_2O —is spontaneous. (c) The normal boiling point is the temperature at which a vapor at 1 atm is in equilibrium with its liquid. Thus, this is an equilibrium situation. If the temperature were below 80.1°C , condensation would be spontaneous.

PRACTICE EXERCISE

At 1 atm pressure, $\text{CO}_2(\text{s})$ sublimates at -78°C . Is this process spontaneous at -100°C and 1 atm pressure?

Answer: No, the reverse process is spontaneous at this temperature.

Seeking a Criterion for Spontaneity

A marble rolling down an incline or a brick falling from your hand loses potential energy. The loss of some form of energy is a common feature of spontaneous change in mechanical systems. During the 1870s Marcellin Bertholet (1827–1907), a famous chemist of that era, suggested that the direction of spontaneous changes in chemical systems is determined by the loss of energy. He proposed that all spontaneous chemical and physical changes are exothermic. It takes only a few moments, however, to find exceptions to this generalization. For example, the melting of ice at room temperature is spontaneous and endothermic. Similarly, many spontaneous dissolution processes, such as the dissolving of NH_4NO_3 , are endothermic, as we discovered in Section 13.1. We conclude that although the majority of spontaneous reactions are exothermic, there are spontaneous endothermic ones as well. Clearly, some other factor must be at work in determining the natural direction of processes.

To understand why certain processes are spontaneous, we need to consider more closely the ways in which the state of a system can change. Recall from Section 5.2 that quantities such as temperature, internal energy, and enthalpy are *state functions*, properties that define a state and do not depend on how we reach that state. The heat transferred between a system and its surroundings, q , and the work done by or on the system, w , are *not* state functions—their values depend on the specific path taken between states. One key to understanding spontaneity is understanding differences in the paths between states.

Reversible and Irreversible Processes

In 1824 a 28-year-old French engineer named Sadi Carnot (1796–1832) published an analysis of the factors that determine how efficiently a steam engine can convert heat to work. Carnot considered what an *ideal engine*, one with the highest possible efficiency, would be like. He observed that it is impossible to convert the energy content of a fuel completely to work because a significant amount of heat is always lost to the surroundings. Carnot's analysis gave insight into how to build better, more efficient engines, and it was one of the earliest studies in what has developed into the discipline of thermodynamics.

An ideal engine operates under an ideal set of conditions in which all the processes are reversible. A **reversible process** is a specific way in which a system changes its state. In a reversible process, the change occurs in such a way that the system and surroundings can be restored to their original states by *exactly* reversing the change. In other words, we can restore the system to its original condition with no net change to either the system or its surroundings. An **irreversible process** is one that cannot simply be reversed to restore the system and its surroundings to their original states. What Carnot discovered is that the amount of work we can extract from any process depends on the manner in which the process is carried out. He concluded that *a reversible change produces the maximum amount of work that can be done by a system on its surroundings*.

GO FIGURE

If the flow of heat into or out of the system is to be reversible, what must be true of δT ?

◀ **FIGURE 19.4** Reversible flow of heat. Heat can flow reversibly between a system and its surroundings only if the two have an infinitesimally small difference in temperature δT . (a) Increasing the temperature of the system by δT causes heat to flow from the hotter system to the colder surroundings. (b) Decreasing the temperature of the system by δT causes heat to flow from the hotter surroundings to the colder system.

GIVE IT SOME THOUGHT

Suppose you have a system made up of water only, with the container and everything beyond being the surroundings. Consider a process in which the water is first evaporated and then condensed back into its original container. Is this two-step process necessarily reversible?

Let's next examine some aspects of reversible and irreversible processes, first with respect to the transfer of heat. When two objects at different temperatures are in contact, heat flows spontaneously from the hotter object to the colder one. Because it is impossible to make heat flow in the opposite direction, from colder object to hotter one, the flow of heat is an irreversible process. Given these facts, can we imagine any conditions under which heat transfer can be made reversible?

To answer this question, we must consider temperature differences that are infinitesimally small, as opposed to the discrete temperature differences with which we are most familiar. For example, consider a system and its surroundings at essentially the same temperature, with just an infinitesimal temperature difference δT between them (▲ **FIGURE 19.4**). If the surroundings are at temperature T and the system is at the infinitesimally higher temperature $T + \delta T$, then an infinitesimal amount of heat flows from system to surroundings. We can reverse the direction of heat flow by making an infinitesimal change of temperature in the opposite direction, lowering the system temperature to $T - \delta T$. Now the direction of heat flow is from surroundings to system. *Reversible processes are those that reverse direction whenever an infinitesimal change is made in some property of the system.**

Now let's consider another example, the expansion of an ideal gas at constant temperature (referred to as an **isothermal process**). In the cylinder-piston arrangement of ▼ **FIGURE 19.5**, when the partition is removed, the gas expands spontaneously to fill the

◀ **FIGURE 19.5** An irreversible process. Initially an ideal gas is confined to the right half of a cylinder. When the partition is removed, the gas spontaneously expands to fill the whole cylinder. No work is done by the system during this expansion. Using the piston to compress the gas back to its original state requires the surroundings to do work on the system.

*For a process to be truly reversible, the amounts of heat must be infinitesimally small and the transfer of heat must occur infinitely slowly; thus, no process that we can observe is truly reversible. The notion of infinitesimal amounts are related to the infinitesimals that you may have studied in a calculus course.

evacuated space. Can we determine whether this particular isothermal expansion is reversible or irreversible? Because the gas expands into a vacuum with no external pressure, it does no P - V work on the surroundings. ∞ (Section 5.3) Thus, for the expansion, $w = 0$. We can use the piston to compress the gas back to its original state, but doing so requires that the surroundings do work on the system, meaning that $w > 0$ for the compression. In other words, the path that restores the system to its original state requires a different value of w (and, by the first law, a different value of q) than the path by which the system was first changed. The fact that the same path can't be followed to restore the system to its original state indicates that the process is irreversible.

What might a *reversible* isothermal expansion of an ideal gas be? This process will occur only if initially, when the gas is confined to half the cylinder, the external pressure acting on the piston exactly balances the pressure exerted by the gas on the piston. If the external pressure is reduced infinitely slowly, the piston will move outward, allowing the pressure of the confined gas to readjust to maintain the pressure balance. This infinitely slow process in which the external pressure and internal pressure are always in equilibrium is reversible. If we reverse the process and compress the gas in the same infinitely slow manner, we can return the gas to its original volume. The complete cycle of expansion and compression in this hypothetical process, moreover, is accomplished without any net change to the surroundings.

Because real processes can at best only approximate the infinitely slow change associated with reversible processes, all real processes are irreversible. Further, as noted earlier in this discussion, the reverse of any spontaneous process is a nonspontaneous process. A nonspontaneous process can occur only if the surroundings do work on the system. Thus, *any spontaneous process is irreversible*. Even if we return the system to the original condition, the surroundings will have changed.

19.2 ENTROPY AND THE SECOND LAW OF THERMODYNAMICS

How can we use the fact that any spontaneous process is irreversible to make predictions about the spontaneity of an unfamiliar process? Understanding spontaneity requires us to examine the thermodynamic quantity called **entropy**, which was first mentioned in Section 13.1. In general, entropy is associated either with the extent of *randomness* in a system or with the extent to which energy is distributed among the various motions of the molecules of the system. In this section we consider how we can relate entropy changes to heat transfer and temperature. Our analysis will bring us to a profound statement about spontaneity that we call the second law of thermodynamics.

Entropy Change

The entropy, S , of a system is a state function just like internal energy, E , and enthalpy, H . As with these other quantities, the value of S is a characteristic of the state of a system. ∞ (Section 5.2) Thus, the change in entropy, ΔS , in a system depends only on the initial and final states of the system and not on the path taken from one state to the other:

$$\Delta S = S_{\text{final}} - S_{\text{initial}} \quad [19.1]$$

For the special case of an isothermal process, ΔS is equal to the heat that would be transferred if the process were reversible, q_{rev} , divided by the absolute temperature at which the process occurs:

$$\Delta S = \frac{q_{\text{rev}}}{T} \quad (\text{constant } T) \quad [19.2]$$

Although there are many possible paths that can take the system from one state to another, only one path is associated with a reversible process. Thus, the value of q_{rev} is uniquely defined for any two states of the system. Because S is a state function, we can use Equation 19.2 to calculate ΔS for *any* isothermal process between states, not just the reversible one.

GIVE IT SOME THOUGHT

How do we reconcile the fact that S is a state function but ΔS depends on q , which is not a state function?

ΔS for Phase Changes

The melting of a substance at its melting point and the vaporization of a substance at its boiling point are isothermal processes. ∞ (Section 11.4) Consider the melting of ice. At 1 atm pressure, ice and liquid water are in equilibrium at 0°C . Imagine melting 1 mol of ice at 0°C , 1 atm to form 1 mol of liquid water at 0°C , 1 atm. We can achieve this change by adding a certain amount of heat to the system from the surroundings: $q = \Delta H_{\text{fusion}}$. Now imagine that we add the heat infinitely slowly, raising the temperature of the surroundings only infinitesimally above 0°C . When we make the change in this fashion, the process is reversible because we can reverse it by infinitely slowly removing the same amount of heat, ΔH_{fusion} , from the system, using immediate surroundings that are infinitesimally below 0°C . Thus, $q_{\text{rev}} = \Delta H_{\text{fusion}}$ for the melting of ice at $T = 0^\circ\text{C} = 273\text{ K}$.

The enthalpy of fusion for H_2O is $\Delta H_{\text{fusion}} = 6.01\text{ kJ/mol}$ (a positive value because melting is an endothermic process). Thus, we can use Equation 19.2 to calculate ΔS_{fusion} for melting 1 mol of ice at 273 K:

$$\Delta S_{\text{fusion}} = \frac{q_{\text{rev}}}{T} = \frac{\Delta H_{\text{fusion}}}{T} = \frac{(1\text{ mol})(6.01 \times 10^3\text{ J/mol})}{273\text{ K}} = 22.0\text{ J/K}$$

Notice (a) that we must use the absolute temperature in Equation 19.2 and (b) that the units for ΔS , J/K, are energy divided by absolute temperature, as we expect from Equation 19.2.

SAMPLE EXERCISE 19.2 Calculating ΔS for a Phase Change

Elemental mercury is a silver liquid at room temperature. Its normal freezing point is -38.9°C , and its molar enthalpy of fusion is $\Delta H_{\text{fusion}} = 2.29\text{ kJ/mol}$. What is the entropy change of the system when 50.0 g of $\text{Hg}(l)$ freezes at the normal freezing point?

SOLUTION

Analyze We first recognize that freezing is an *exothermic* process, which means heat is transferred from system to surroundings and $q < 0$. The enthalpy of fusion refers to the process of melting. Because freezing is the reverse of melting, the enthalpy change that accompanies the freezing of 1 mol of Hg is $-\Delta H_{\text{fusion}} = -2.29\text{ kJ/mol}$.

Plan We can use $-\Delta H_{\text{fusion}}$ and the atomic weight of Hg to calculate q for freezing 50.0 g of Hg. Then we use this value of q as q_{rev} in Equation 19.2 to determine ΔS for the system.

Solve

For q we have

$$q = (50.0\text{ g Hg})\left(\frac{1\text{ mol Hg}}{200.59\text{ g Hg}}\right)\left(\frac{-2.29\text{ kJ}}{1\text{ mol Hg}}\right)\left(\frac{1000\text{ J}}{1\text{ kJ}}\right) = -571$$

Before using Equation 19.2, we must first convert the given Celsius temperature to kelvins:

$$-38.9^\circ\text{C} = (-38.9 + 273.15)\text{ K} = 234.3\text{ K}$$

We can now calculate ΔS_{sys} :

$$\Delta S_{\text{sys}} = \frac{q_{\text{rev}}}{T} = \frac{-571\text{ J}}{234.3\text{ K}} = -2.44\text{ J/K}$$

Check The entropy change is negative because our q_{rev} value is negative, which it must be because heat flows out of the system in this exothermic process.

Comment This procedure can be used to calculate ΔS for other isothermal phase changes, such as the vaporization of a liquid at its boiling point.

PRACTICE EXERCISE

The normal boiling point of ethanol, $\text{C}_2\text{H}_5\text{OH}$, is 78.3°C , and its molar enthalpy of vaporization is 38.56 kJ/mol . What is the change in entropy in the system when 68.3 g of $\text{C}_2\text{H}_5\text{OH}(g)$ at 1 atm condenses to liquid at the normal boiling point?

Answer: -163 J/K

A CLOSER LOOK

THE ENTROPY CHANGE WHEN A GAS EXPANDS ISOTHERMALLY

In general, the entropy of any system increases as the system becomes more random or more spread out.

Thus, we expect the spontaneous expansion of a gas to result in an increase in entropy. To see how this entropy increase can be calculated, consider the expansion of an ideal gas that is initially constrained by a piston, as in the right-most part of Figure 19.5. Imagine that we allow the gas to undergo a reversible isothermal expansion by infinitesimally decreasing the external pressure on the piston. The work done on the surroundings by the reversible expansion of the system against the piston can be calculated with the aid of calculus (we do not show the derivation):

$$w_{\text{rev}} = -nRT \ln \frac{V_2}{V_1}$$

In this equation, n is the number of moles of gas, R is the gas constant (Section 10.4), T is the absolute temperature, V_1 is the initial volume, and V_2 is the final volume. Notice that if $V_2 > V_1$, as it must be in our expansion, then $w_{\text{rev}} < 0$, meaning that the expanding gas does work on the surroundings.

One characteristic of an ideal gas is that its internal energy depends only on temperature, not on pressure. Thus, when an ideal

gas expands isothermally, $\Delta E = 0$. Because $\Delta E = q_{\text{rev}} + w_{\text{rev}} = 0$, we see that $q_{\text{rev}} = -w_{\text{rev}} = nRT \ln(V_2/V_1)$. Then, using Equation 19.2, we can calculate the entropy change in the system:

$$\Delta S_{\text{sys}} = \frac{q_{\text{rev}}}{T} = \frac{nRT \ln \frac{V_2}{V_1}}{T} = nR \ln \frac{V_2}{V_1} \quad [19.3]$$

From the ideal-gas equation, we can calculate the number of moles in 1.00 L of an ideal gas at 1.00 atm and 0 °C by using the value 0.08206 L-atm/mol-K for R :

$$n = \frac{PV}{RT} = \frac{(1.00 \text{ atm})(1.00 \text{ L})}{(0.08206 \text{ L-atm/mol-K})(273 \text{ K})} = 4.46 \times 10^{-2} \text{ mol}$$

The gas constant, R , can also be expressed as 8.314 J/mol-K (Table 10.2), and this is the value we must use in Equation 19.3 because we want our answer to be expressed in terms of J rather than in L-atm. Thus, for the expansion of the gas from 1.00 L to 2.00 L, we have

$$\begin{aligned} \Delta S_{\text{sys}} &= (4.46 \times 10^{-2} \text{ mol}) \left(8.314 \frac{\text{J}}{\text{mol-K}} \right) \left(\ln \frac{2.00 \text{ L}}{1.00 \text{ L}} \right) \\ &= 0.26 \text{ J/K} \end{aligned}$$

In Section 19.3 we will see that this increase in entropy is a measure of the increased randomness of the molecules because of the expansion.

RELATED EXERCISES: 19.29, 19.30, and 19.106

The Second Law of Thermodynamics

The key idea of the first law of thermodynamics is that energy is conserved in any process. (Section 5.2) Entropy, however, is not conserved. For any spontaneous process, the total change in entropy, which is the sum of the entropy change of the system plus the entropy change of the surroundings, is greater than zero.

Let's illustrate this generalization by calculating the entropy change of a system and the entropy change of its surroundings when our system is 1 mol of ice (a piece roughly the size of an ice cube) melting in the palm of your hand, which is part of the surroundings. The process is not reversible because the system and surroundings are at different temperatures. Nevertheless, because ΔS is a state function, its value is the same regardless of whether the process is reversible or irreversible. We calculated the entropy change of the system just before Sample Exercise 19.2:

$$\Delta S_{\text{sys}} = \frac{q_{\text{rev}}}{T} = \frac{(1 \text{ mol})(6.01 \times 10^3 \text{ J/mol})}{273 \text{ K}} = 22.0 \text{ J/K}$$

The surroundings immediately in contact with the ice are your hand, which we assume is at body temperature, 37 °C = 310 K. The quantity of heat lost by your hand is $-6.01 \times 10^3 \text{ J/mol}$, which is equal in magnitude to the quantity of heat gained by the ice but has the opposite sign. Hence, the entropy change of the surroundings is

$$\Delta S_{\text{surr}} = \frac{q_{\text{rev}}}{T} = \frac{(1 \text{ mol})(-6.01 \times 10^3 \text{ J/mol})}{310 \text{ K}} = -19.4 \text{ J/K}$$

Thus, the total entropy change is positive:

$$\Delta S_{\text{total}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} = (22.0 \text{ J/K}) + (-19.4 \text{ J/K}) = 2.6 \text{ J/K}$$

If the temperature of the surroundings were not 310 K but rather some temperature infinitesimally above 273 K, the melting would be reversible instead of irreversible. In that case the entropy change of the surroundings would equal -22.0 J/K and ΔS_{total} would be zero.

In general, any irreversible process results in an increase in total entropy, whereas any reversible process results in no overall change in entropy. This statement is known as the **second law of thermodynamics**.

The sum of the entropy of a system plus the entropy of the surroundings is everything there is, and so we refer to the total entropy change as the entropy change of the universe, ΔS_{univ} . We can therefore state the second law of thermodynamics in terms of two equations:

$$\begin{aligned} \text{Reversible Process: } \Delta S_{\text{univ}} &= \Delta S_{\text{sys}} + \Delta S_{\text{surr}} = 0 \\ \text{Irreversible Process: } \Delta S_{\text{univ}} &= \Delta S_{\text{sys}} + \Delta S_{\text{surr}} > 0 \end{aligned} \quad [19.4]$$

Because spontaneous processes are irreversible, we can say that *the entropy of the universe increases in any spontaneous process*. This profound generalization is yet another way of expressing the second law of thermodynamics.

GIVE IT SOME THOUGHT

The rusting of iron is spontaneous and is accompanied by a decrease in the entropy of the system (the iron and oxygen). What can we conclude about the entropy change of the surroundings?

The second law of thermodynamics tells us the essential character of any spontaneous change—it is always accompanied by an increase in the entropy of the universe. We can use this criterion to predict whether a given process is spontaneous or not. Before seeing how this is done, however, we will find it useful to explore entropy from a molecular perspective.

A word on notation before we proceed. Throughout most of the remainder of this chapter, we will focus on systems rather than surroundings. To simplify the notation, we will usually refer to the entropy change of the system as ΔS rather than explicitly indicating ΔS_{sys} .

19.3 MOLECULAR INTERPRETATION OF ENTROPY

As chemists, we are interested in molecules. What does entropy have to do with them and with their transformations? What molecular property does entropy reflect? Ludwig Boltzmann (1844–1906) gave conceptual meaning to the notion of entropy, and to understand his contribution, we need to examine the ways in which we can interpret entropy at the molecular level.

Expansion of a Gas at the Molecular Level

In discussing Figure 19.2, we talked about the expansion of a gas into a vacuum as a spontaneous process. We now understand that it is an irreversible process and that the entropy of the universe increases during the expansion. How can we explain the spontaneity of this process at the molecular level? We can get a sense of what makes this expansion spontaneous by envisioning the gas as a collection of particles in constant motion, as we did in discussing the kinetic-molecular theory of gases.  (Section 10.7) When the stopcock in Figure 19.2 is opened, we can view the expansion of the gas as the ultimate result of the gas molecules moving randomly throughout the larger volume.

Let's look at this idea more closely by tracking two of the gas molecules as they move around. Before the stopcock is opened, both molecules are confined to the left flask, as shown in  **FIGURE 19.6(a)**. After the stopcock is opened, the molecules travel randomly throughout the entire apparatus. As Figure 19.6(b) shows, there are four possible arrangements for the two molecules once both flasks are available to them. Because the molecular motion is random, all four arrangements are equally likely. Note that now only one arrangement corresponds to the situation before the stopcock was opened: both molecules in the left flask.

▲ **FIGURE 19.6** Possible arrangements of two gas molecules in two flasks. (a) Before the stopcock is opened, both molecules are in the left flask. (b) After the stopcock is opened, there are four possible arrangements of the two molecules.

Figure 19.6(b) shows that with both flasks available to the molecules, the probability of the red molecule being in the left flask is two in four (top right and bottom left arrangements), and the probability of the blue molecule being in the left flask is the same (top left and bottom left arrangements). Because the probability is $\frac{2}{4} = \frac{1}{2}$ that each molecule is in the left flask, the probability that *both* are there is $(\frac{1}{2})^2 = \frac{1}{4}$. If we apply the same analysis to *three* gas molecules, we find that the probability that all three are in the left flask at the same time is $(\frac{1}{2})^3 = \frac{1}{8}$.

Now let's consider a *mole* of gas. The probability that all the molecules are in the left flask at the same time is $(\frac{1}{2})^N$, where $N = 6.02 \times 10^{23}$. This is a vanishingly small number! Thus, there is essentially zero likelihood that all the gas molecules will be in the left flask at the same time. This analysis of the microscopic behavior of the gas molecules leads to the expected macroscopic behavior: The gas spontaneously expands to fill both the left and right flasks, and it does not spontaneously all go back in the left flask.

This molecular view of gas expansion shows the tendency of the molecules to “spread out” among the different arrangements they can take. Before the stopcock is opened, there is only one possible arrangement: all molecules in the left flask. When the stopcock is opened, the arrangement in which all the molecules are in the left flask is but one of an extremely large number of possible arrangements. The most probable arrangements by far are those in which there are essentially equal numbers of molecules in the two flasks. When the gas spreads throughout the apparatus, any given molecule can be in either flask rather than confined to the left flask. We say that with the stopcock opened, the arrangement of gas molecules is more random or disordered than when the molecules are all confined in the left flask.

We will see this notion of increasing randomness helps us understand entropy at the molecular level.

Boltzmann's Equation and Microstates

The science of thermodynamics developed as a means of describing the properties of matter in our macroscopic world without regard to microscopic structure. In fact, thermodynamics was a well-developed field before the modern view of atomic and molecular structure was even known. The thermodynamic properties of water, for example, addressed the behavior of bulk water (or ice or water vapor) as a substance without considering any specific properties of individual H_2O molecules.

To connect the microscopic and macroscopic descriptions of matter, scientists have developed the field of *statistical thermodynamics*, which uses the tools of statistics and probability to link the microscopic and macroscopic worlds. Here we show how entropy, which is a property of bulk matter, can be connected to the behavior of atoms and molecules. Because the mathematics of statistical thermodynamics is complex, our discussion will be largely conceptual.

In our discussion of two gas molecules in the two-flask system in Figure 19.6, we saw that the number of possible arrangements helped explain why the gas expands.

Suppose we now consider one mole of an ideal gas in a particular thermodynamic state, which we can define by specifying the temperature, T , and volume, V , of the gas. What is happening to this gas at the microscopic level, and how does what is going on at the microscopic level relate to the entropy of the gas?

Imagine taking a snapshot of the positions and speeds of all the molecules at a given instant. The speed of each molecule tells us its kinetic energy. That particular set of 6×10^{23} positions and kinetic energies of the individual gas molecules is what we call a *microstate* of the system. A **microstate** is a single possible arrangement of the positions and kinetic energies of the gas molecules when the gas is in a specific thermodynamic state. We could envision continuing to take snapshots of our system to see other possible microstates.

As you no doubt see, there would be such a staggeringly large number of microstates that taking individual snapshots of all of them is not feasible. Because we are examining such a large number of particles, however, we can use the tools of statistics and probability to determine the total number of microstates for the thermodynamic state. (That is where the *statistical* part of the name *statistical thermodynamics* comes in.) Each thermodynamic state has a characteristic number of microstates associated with it, and we will use the symbol W for that number.

Students sometimes have difficulty distinguishing between the state of a system and the microstates associated with the state. The difference is that *state* is used to describe the macroscopic view of our system as characterized, for example, by the pressure or temperature of a sample of gas. A *microstate* is a particular microscopic arrangement of the atoms or molecules of the system that corresponds to the given state of the system. Each of the snapshots we described is a microstate—the positions and kinetic energies of individual gas molecules will change from snapshot to snapshot, but each one is a possible arrangement of the collection of molecules corresponding to a single state. For macroscopically sized systems, such as a mole of gas, there is a very large number of microstates for each state—that is, W is generally an extremely large number.

The connection between the number of microstates of a system, W , and the entropy of the system, S , is expressed in a beautifully simple equation developed by Boltzmann and engraved on his tombstone (► **FIGURE 19.7**):

$$S = k \ln W \quad [19.5]$$

In this equation, k is Boltzmann's constant, 1.38×10^{-23} J/K. Thus, *entropy is a measure of how many microstates are associated with a particular macroscopic state.*

▲ GIVE IT SOME THOUGHT

What is the entropy of a system that has only a single microstate?

From Equation 19.5, we see that the entropy change accompanying any process is

$$\Delta S = k \ln W_{\text{final}} - k \ln W_{\text{initial}} = k \ln \frac{W_{\text{final}}}{W_{\text{initial}}} \quad [19.6]$$

Any change in the system that leads to an increase in the number of microstates ($W_{\text{final}} > W_{\text{initial}}$) leads to a positive value of ΔS : *Entropy increases with the number of microstates of the system.*

Let's consider two modifications to our ideal-gas sample and see how the entropy changes in each case. First, suppose we increase the volume of the system, which is analogous to allowing the gas to expand isothermally. A greater volume means a greater number of positions available to the gas atoms and therefore a greater number of microstates. The entropy therefore increases as the volume increases, as we saw in the "A Closer Look" box in Section 19.2.

▲ **FIGURE 19.7** Ludwig Boltzmann's gravestone. Boltzmann's gravestone in Vienna is inscribed with his famous relationship between the entropy of a state, S , and the number of available microstates, W . (In Boltzmann's time, "log" was used to represent the natural logarithm.)

Second, suppose we keep the volume fixed but increase the temperature. How does this change affect the entropy of the system? Recall the distribution of molecular speeds presented in Figure 10.17(a). An increase in temperature increases the most probable speed of the molecules and also broadens the distribution of speeds. Hence, the molecules have a greater number of possible kinetic energies, and the number of microstates increases. Thus, the entropy of the system increases with increasing temperature.

Molecular Motions and Energy

When a substance is heated, the motion of its molecules increases. In Section 10.7, we found that the average kinetic energy of the molecules of an ideal gas is directly proportional to the absolute temperature of the gas. That means the higher the temperature, the faster the molecules move and the more kinetic energy they possess. Moreover, hotter systems have a *broader distribution* of molecular speeds, as Figure 10.17(a) shows.

The particles of an ideal gas are idealized points with no volume and no bonds, however, points that we visualize as flitting around through space. Any real molecule can undergo three kinds of more complex motion. The entire molecule can move in one direction, which is the simple motion we visualize for an ideal particle and see in a macroscopic object, such as a thrown baseball. We call such movement **translational motion**. The molecules in a gas have more freedom of translational motion than those in a liquid, which have more freedom of translational motion than the molecules of a solid.

A real molecule can also undergo **vibrational motion**, in which the atoms in the molecule move periodically toward and away from one another, and **rotational motion**, in which the molecule spins about an axis. ▼ **FIGURE 19.8** shows the vibrational motions and one of the rotational motions possible for the water molecule. These different forms of motion are ways in which a molecule can store energy, and we refer to the various forms collectively as the *motional energy* of the molecule.

▲ GIVE IT SOME THOUGHT

What kinds of motion can a molecule undergo that a single atom cannot?

The vibrational and rotational motions possible in real molecules lead to arrangements that a single atom can't have. A collection of real molecules therefore has a greater number of possible microstates than does the same number of ideal-gas particles. In general, *the number of microstates possible for a system increases with an increase in volume, an increase in temperature, or an increase in the number of molecules because any of these changes increases the possible positions and kinetic energies of the molecules making up the system.* We will also see that the number of microstates increases as the complexity of the molecule increases because there are more vibrational motions available.

Chemists have several ways of describing an increase in the number of microstates possible for a system and therefore an increase in the entropy for the system. Each way seeks to capture a sense of the increased freedom of motion that causes molecules to spread out when not restrained by physical barriers or chemical bonds.

▲ GO FIGURE

Describe another possible rotational motion for this molecule.

► **FIGURE 19.8** Vibrational and rotational motions in a water molecule.

The most common way for describing an increase in entropy is as an increase in the *randomness*, or *disorder*, of the system. Another way likens an entropy increase to an increased *dispersion (spreading out) of energy* because there is an increase in the number of ways the positions and energies of the molecules can be distributed throughout the system. Each description (randomness or energy dispersal) is conceptually helpful if applied correctly.

Making Qualitative Predictions About ΔS

It is usually not difficult to estimate qualitatively how the entropy of a system changes during a simple process. As noted earlier, an increase in either the temperature or the volume of a system leads to an increase in the number of microstates, and hence an increase in the entropy. One more factor that correlates with number of microstates is the number of independently moving particles.

We can usually make qualitative predictions about entropy changes by focusing on these factors. For example, when water vaporizes, the molecules spread out into a larger volume. Because they occupy a larger volume, there is an increase in their freedom of motion, giving rise to a greater number of possible microstates, and hence an increase in entropy.

Now consider the phases of water. In ice, hydrogen bonding leads to the rigid structure shown in **FIGURE 19.9**. Each molecule in the ice is free to vibrate, but its translational and rotational motions are much more restricted than in liquid water. Although there are hydrogen bonds in liquid water, the molecules can more readily move about relative to one another (translation) and tumble around (rotation). During melting, therefore, the number of possible microstates increases and so does the entropy. In water vapor, the molecules are essentially independent of one another and have their full range of translational, vibrational, and rotational motions. Thus, water vapor has an even greater number of possible microstates and therefore a higher entropy than liquid water or ice.

GO FIGURE

In which phase are water molecules least able to have rotational motion?

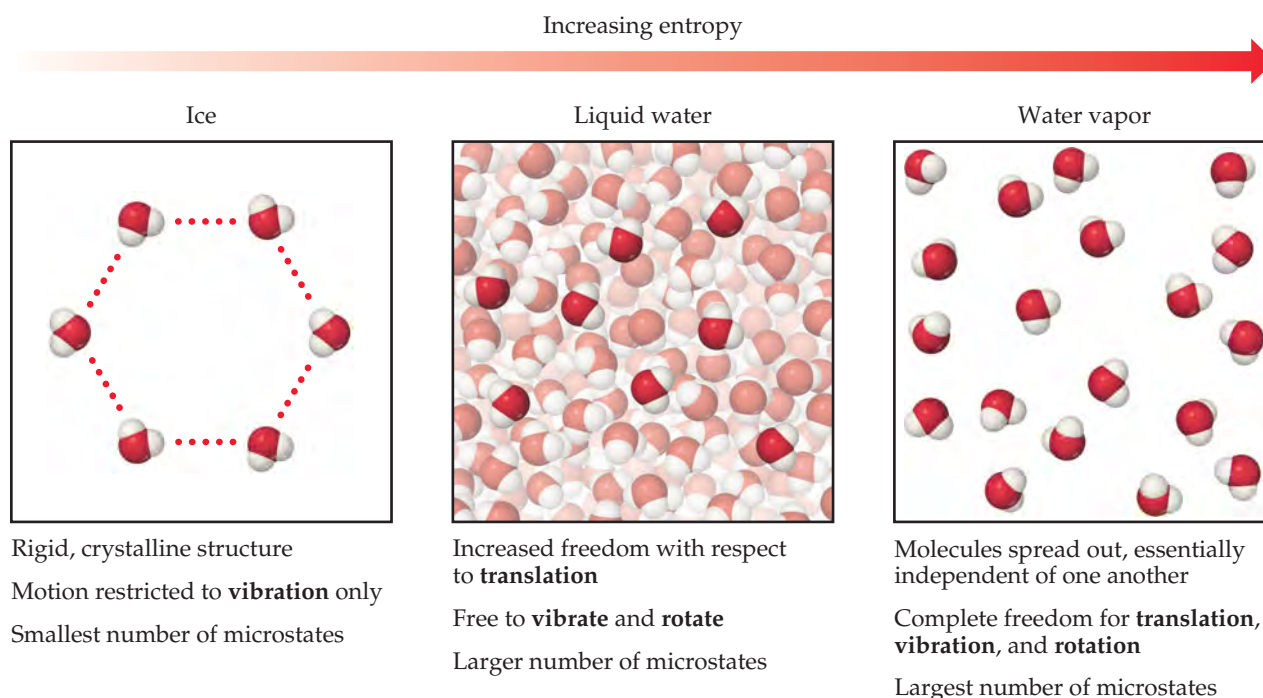

FIGURE 19.9 Entropy and the phases of water. The larger the number of possible microstates, the higher the entropy of the system.

▲ FIGURE 19.10 Entropy changes when an ionic solid dissolves in water. The ions become more spread out and disordered, but the water molecules that hydrate the ions become less disordered.

When an ionic solid dissolves in water, a mixture of water and ions replaces the pure solid and pure water, as shown for KCl in ◀ **FIGURE 19.10**. The ions in the liquid move in a volume that is larger than the volume in which they were able to move in the crystal lattice and so possess more motional energy. This increased motion might lead us to conclude that the entropy of the system has increased. We have to be careful, however, because some of the water molecules have lost some freedom of motion because they are now held around the ions as water of hydration. ∞ (Section 13.1) These water molecules are in a *more* ordered state than before because they are now confined to the immediate environment of the ions. Therefore, the dissolving of a salt involves both a disordering process (the ions become less confined) and an ordering process (some water molecules become more confined). The disordering processes are usually dominant, and so the overall effect is an increase in the randomness of the system when most salts dissolve in water.

The same ideas apply to chemical reactions. Consider the reaction between nitric oxide gas and oxygen gas to form nitrogen dioxide gas:

which results in a decrease in the number of molecules—three molecules of gaseous reactants form two molecules of gaseous products (▶ **FIGURE 19.11**). The formation of new N—O bonds reduces the motions of the atoms in the system. The formation of new bonds decreases the *number of degrees of freedom*, or forms of motion, available to the atoms. That is, the atoms are less free to move in random fashion because of the formation of new bonds. The decrease in the number of molecules and the resultant decrease in motion result in fewer possible microstates and therefore a decrease in the entropy of the system.

In summary, we generally expect the entropy of a system to increase for processes in which

1. Gases form from either solids or liquids.
2. Liquids or solutions form from solids.
3. The number of gas molecules increases during a chemical reaction.

SAMPLE EXERCISE 19.3 Predicting the Sign of ΔS

Predict whether ΔS is positive or negative for each process, assuming each occurs at constant temperature:

- (a) $\text{H}_2\text{O}(l) \longrightarrow \text{H}_2\text{O}(g)$
- (b) $\text{Ag}^+(aq) + \text{Cl}^-(aq) \longrightarrow \text{AgCl}(s)$
- (c) $4 \text{Fe}(s) + 3 \text{O}_2(g) \longrightarrow 2 \text{Fe}_2\text{O}_3(s)$
- (d) $\text{N}_2(g) + \text{O}_2(g) \longrightarrow 2 \text{NO}(g)$

SOLUTION

Analyze We are given four reactions and asked to predict the sign of ΔS for each.

Plan We expect ΔS to be positive if there is an increase in temperature, increase in volume, or increase in number of gas particles. The question states that the temperature is constant, and so we need to concern ourselves only with volume and number of particles.

Solve

(a) Evaporation involves a large increase in volume as liquid changes to gas. One mole of water (18 g) occupies about 18 mL as a liquid and if it could exist as a gas at STP it would occupy 22.4 L. Because the molecules are distributed throughout a much larger volume in the gaseous state, an increase in motional freedom accompanies vaporization and ΔS is positive.

(b) In this process, ions, which are free to move throughout the volume of the solution, form a solid, in which they are confined to a smaller volume and restricted to more highly constrained positions. Thus, ΔS is negative.

(c) The particles of a solid are confined to specific locations and have fewer ways to move (fewer microstates) than do the molecules of a gas. Because O_2 gas is converted into part of the solid product Fe_2O_3 , ΔS is negative.

(d) The number of moles of reactant gases is the same as the number of moles of product gases, and so the entropy change is expected to be small. The sign of ΔS is impossible to predict based on our discussions thus far, but we can predict that ΔS will be close to zero.

PRACTICE EXERCISE

Indicate whether each process produces an increase or decrease in the entropy of the system:

- (a) $\text{CO}_2(s) \longrightarrow \text{CO}_2(g)$
 (b) $\text{CaO}(s) + \text{CO}_2(g) \longrightarrow \text{CaCO}_3(s)$
 (c) $\text{HCl}(g) + \text{NH}_3(g) \longrightarrow \text{NH}_4\text{Cl}(s)$
 (d) $2 \text{SO}_2(g) + \text{O}_2(g) \longrightarrow 2 \text{SO}_3(g)$

Answers: (a) increase, (b) decrease, (c) decrease, (d) decrease

SAMPLE EXERCISE 19.4 Predicting Relative Entropies

In each pair, choose the system that has greater entropy and explain your choice: (a) 1 mol of $\text{NaCl}(s)$ or 1 mol of $\text{HCl}(g)$ at 25 °C, (b) 2 mol of $\text{HCl}(g)$ or 1 mol of $\text{HCl}(g)$ at 25 °C, (c) 1 mol of $\text{HCl}(g)$ or 1 mol of $\text{Ar}(g)$ at 298 K.

SOLUTION

Analyze We need to select the system in each pair that has the greater entropy.

Plan We examine the state of each system and the complexity of the molecules it contains.

Solve

(a) $\text{HCl}(g)$ has the higher entropy because the particles in gases are more disordered and have more freedom of motion than the particles in solids. (b) When these two systems are at the same pressure, the sample containing 2 mol of HCl has twice the number of molecules as the sample containing 1 mol. Thus, the 2-mol sample has twice the number of microstates and twice the entropy. (c) The HCl system has the higher entropy because the number of ways in which an HCl molecule can store energy is greater than the number of ways in which an Ar atom can store energy. (Molecules can rotate and vibrate; atoms cannot.)

PRACTICE EXERCISE

Choose the system with the greater entropy in each case: (a) 1 mol of $\text{H}_2(g)$ at STP or 1 mol of $\text{H}_2(g)$ at 100 °C and 0.5 atm, (b) 1 mol of $\text{H}_2\text{O}(s)$ at 0 °C or 1 mol of $\text{H}_2\text{O}(l)$ at 25 °C, (c) 1 mol of $\text{H}_2(g)$ at STP or 1 mol of $\text{SO}_2(g)$ at STP, (d) 1 mol of $\text{N}_2\text{O}_4(g)$ at STP or 2 mol of $\text{NO}_2(g)$ at STP.

Answers: (a) 1 mol of $\text{H}_2(g)$ at 100 °C and 0.5 atm, (b) 1 mol of $\text{H}_2\text{O}(l)$ at 25 °C, (c) 1 mol of $\text{SO}_2(g)$ at STP, (d) 2 mol of $\text{NO}_2(g)$ at STP

The Third Law of Thermodynamics

If we decrease the thermal energy of a system by lowering the temperature, the energy stored in translational, vibrational, and rotational motion decreases. As less energy is stored, the entropy of the system decreases. If we keep lowering the temperature, do we reach a state in which these motions are essentially shut down, a point described by a single microstate? This question is addressed by the **third law of thermodynamics**, which states that *the entropy of a pure crystalline substance at absolute zero is zero: $S(0 \text{ K}) = 0$* .

Consider a pure crystalline solid. At absolute zero, the individual atoms or molecules in the lattice would be perfectly ordered and as well defined in position as they could be. Because none of them would have thermal motion, there is only one possible microstate. As a result, Equation 19.5 becomes $S = k \ln W = k \ln 1 = 0$. As the temperature is increased from absolute zero, the atoms or molecules in the crystal gain energy in the form of vibrational motion about their lattice positions. This means that the degrees of freedom and the entropy both increase. What happens to the entropy, however, as we continue to heat the crystal? We consider this important question in the next section.

GIVE IT SOME THOUGHT

If you are told that the entropy of a system is zero, what do you know about the system?

GO FIGURE

What major factor leads to a decrease in entropy as the reaction shown takes place?

▲ FIGURE 19.11 Entropy decreases when $\text{NO}(g)$ is oxidized by $\text{O}_2(g)$ to $\text{NO}_2(g)$. A decrease in the number of gaseous molecules leads to a decrease in the entropy of the system.

CHEMISTRY AND LIFE

ENTROPY AND HUMAN SOCIETY

The laws of thermodynamics have profound implications for our existence. In the “Chemistry Put to Work” box on page 192, we examined some of the scientific and political challenges of using biofuels as a major energy source to maintain our lifestyles. That discussion builds around the first law of thermodynamics, namely, that energy is conserved. We therefore have important decisions to make as to energy production and consumption.

The second law of thermodynamics is also relevant in discussions about our existence and about our ability and desire to advance as a civilization. Any living organism is a complex, highly organized, well-ordered system. Our entropy content is much lower than it would be if we were completely decomposed into carbon dioxide, water, and several other simple chemicals. Does this mean that our existence is a violation of the second law? No, because the thousands of chemical reactions necessary to produce and maintain human life have caused a very large increase in the entropy of the rest of the universe. Thus, as the second law requires, the overall entropy change during the lifetime of a human, or any other living system, is positive.

In addition to being complex living systems ourselves, we humans are masters of producing order in the world around us. As shown in the chapter-opening photograph, we build impressive, highly ordered structures and buildings. We manipulate and order matter at the nanoscale level in order to produce the technological breakthroughs that have become so commonplace in the twenty-first century (► **FIGURE 19.12**). We use tremendous quantities of raw materials to produce highly ordered materials—iron, copper, and a host of other metals from their ores, silicon for computer chips from sand, polymers from fossil fuel feedstocks, and so forth. In so doing, we expend a great deal of energy to, in essence, “fight” the second law of thermodynamics.

For every bit of order we produce, however, we produce an even greater amount of disorder. Petroleum, coal, and natural gas are burned to provide the energy necessary for us to achieve highly ordered structures, but their combustion increases the entropy of the universe by releasing $\text{CO}_2(\text{g})$, $\text{H}_2\text{O}(\text{g})$, and heat. Oxide and sulfide ores release $\text{CO}_2(\text{g})$ and $\text{SO}_2(\text{g})$ that spread throughout our

atmosphere. Thus, even as we strive to create more impressive discoveries and greater order in our society, we drive the entropy of the universe higher, as the second law says we must.

We humans are, in effect, using up our storehouse of energy-rich materials to create order and advance technology. As noted in Chapter 5, we must learn to harness new energy sources, such as solar energy, before we exhaust the supplies of readily available energy of other kinds.

▲ **FIGURE 19.12** Fighting the second law. Creating complex structures, such as the skyscrapers in the chapter-opening photograph, requires that we use energy to produce order while knowing that we are increasing the entropy of the universe. Modern cellular telephones, with their detailed displays and complex circuitry are an example on a smaller scale of the impressive order that human ingenuity achieves.

19.4 ENTROPY CHANGES IN CHEMICAL REACTIONS

In Section 5.5 we discussed how calorimetry can be used to measure ΔH for chemical reactions. No comparable method exists for measuring ΔS for a reaction. However, because the third law establishes a zero point for entropy, we can use experimental measurements to determine the *absolute value of the entropy*, S . To see schematically how this is done, let's review in greater detail the variation in the entropy of a substance with temperature.

We know that the entropy of a pure crystalline solid at 0 K is zero and that the entropy increases as the temperature of the crystal is increased. ► **FIGURE 19.13** shows that the entropy of the solid increases steadily with increasing temperature up to the melting point of the solid. When the solid melts, the atoms or molecules are free to move about the entire volume of the sample. The added degrees of freedom increase the randomness of the substance, thereby increasing its entropy. We therefore see a sharp increase in the entropy at the melting point. After all the solid has melted, the temperature again increases and with it, the entropy.

GO FIGURE

Why does the plot show vertical jumps at the melting and boiling points?

▲ FIGURE 19.13 Entropy increases with increasing temperature.

At the boiling point of the liquid, another abrupt increase in entropy occurs. We can understand this increase as resulting from the increased volume available to the atoms or molecules as they enter the gaseous state. When the gas is heated further, the entropy increases steadily as more energy is stored in the translational motion of the gas atoms or molecules.

Another change that occurs at higher temperatures is that the distribution of molecular speeds is skewed toward higher values. ∞ [Figure 10.17(a)] The expansion of the range of speeds leads to increased kinetic energy and increased disorder and, hence, increased entropy. The conclusions we reach in examining Figure 19.13 are consistent with what we noted earlier: Entropy generally increases with increasing temperature because the increased motional energy leads to a greater number of possible microstates.

Entropy plots such as Figure 19.13 can be obtained by carefully measuring how the heat capacity of a substance ∞ (Section 5.5) varies with temperature, and we can use the data to obtain the absolute entropies at different temperatures. (The theory and methods used for these measurements and calculations are beyond the scope of this text.) Entropies are usually tabulated as molar quantities, in units of joules per mole-kelvin (J/mol-K).

Molar entropies for substances in their standard states are known as **standard molar entropies** and denoted S° . The standard state for any substance is defined as the pure substance at 1 atm pressure.* **► TABLE 19.1** lists the values of S° for a number of substances at 298 K; Appendix C gives a more extensive list.

We can make several observations about the S° values in Table 19.1:

1. Unlike enthalpies of formation, standard molar entropies of elements at the reference temperature of 298 K are *not* zero.
2. The standard molar entropies of gases are greater than those of liquids and solids, consistent with our interpretation of experimental observations, as represented in Figure 19.13.
3. Standard molar entropies generally increase with increasing molar mass.
4. Standard molar entropies generally increase with an increasing number of atoms in the formula of a substance.

Point 4 is related to the molecular motion discussed in Section 19.3. In general, the number of degrees of freedom for a molecule increases with increasing number of

TABLE 19.1 • Standard Molar Entropies of Selected Substances at 298 K

Substance	S° (J/mol-K)
H ₂ (g)	130.6
N ₂ (g)	191.5
O ₂ (g)	205.0
H ₂ O(g)	188.8
NH ₃ (g)	192.5
CH ₃ OH(g)	237.6
C ₆ H ₆ (g)	269.2
H ₂ O(l)	69.9
CH ₃ OH(l)	126.8
C ₆ H ₆ (l)	172.8
Li(s)	29.1
Na(s)	51.4
K(s)	64.7
Fe(s)	27.23
FeCl ₃ (s)	142.3
NaCl(s)	72.3

*The standard pressure used in thermodynamics is no longer 1 atm but rather is based on the SI unit for pressure, the pascal (Pa). The standard pressure is 10^5 Pa, a quantity known as a *bar*: 1 bar = 10^5 Pa = 0.987 atm. Because 1 bar differs from 1 atm by only 1.3%, we will continue to refer to the standard pressure as 1 atm.

GO FIGURE

What might you expect for the value of S° for butane, C_4H_{10} ?

▲ FIGURE 19.14 Entropy increases with increasing molecular complexity.

atoms, and thus the number of possible microstates also increases. **▲ FIGURE 19.14** compares the standard molar entropies of three hydrocarbons in the gas phase. Notice how the entropy increases as the number of atoms in the molecule increases.

The entropy change in a chemical reaction equals the sum of the entropies of the products minus the sum of the entropies of the reactants:

$$\Delta S^\circ = \sum nS^\circ(\text{products}) - \sum mS^\circ(\text{reactants}) \quad [19.8]$$

As in Equation 5.31, the coefficients n and m are the coefficients in the balanced chemical equation for the reaction.

SAMPLE EXERCISE 19.5 Calculating ΔS° from Tabulated Entropies

Calculate the change in the standard entropy of the system, ΔS° , for the synthesis of ammonia from $N_2(g)$ and $H_2(g)$ at 298 K:

SOLUTION

Analyze We are asked to calculate the standard entropy change for the synthesis of $NH_3(g)$ from its constituent elements.

Plan We can make this calculation using Equation 19.8 and the standard molar entropy values in Table 19.1 and Appendix C.

Solve

Using Equation 19.8, we have
$$\Delta S^\circ = 2S^\circ(NH_3) - [S^\circ(N_2) + 3S^\circ(H_2)]$$

Substituting the appropriate S° values from Table 19.1 yields
$$\Delta S^\circ = (2 \text{ mol})(192.5 \text{ J/mol}\cdot\text{K}) - [(1 \text{ mol})(191.5 \text{ J/mol}\cdot\text{K}) + (3 \text{ mol})(130.6 \text{ J/mol}\cdot\text{K})]$$

$$= -198.3 \text{ J/K}$$

Check: The value for ΔS° is negative, in agreement with our qualitative prediction based on the decrease in the number of molecules of gas during the reaction.

PRACTICE EXERCISE

Using the standard molar entropies in Appendix C, calculate the standard entropy change, ΔS° , for the following reaction at 298 K:

Answer: 180.39 J/K

Entropy Changes in the Surroundings

We can use tabulated absolute entropy values to calculate the standard entropy change in a system, such as a chemical reaction, as just described. But what about the entropy change in the surroundings? We encountered this situation in Section 19.2, but it is good to revisit it now that we are examining chemical reactions.

We should recognize that the surroundings for any system serve essentially as a large, constant-temperature heat source (or heat sink if the heat flows from the system to the surroundings). The change in entropy of the surroundings depends on how much heat is absorbed or given off by the system.

For an isothermal process, the entropy change of the surroundings is given by

$$\Delta S_{\text{surr}} = \frac{-q_{\text{sys}}}{T}$$

Because in a constant-pressure process, q_{sys} is simply the enthalpy change for the reaction, ΔH , we can write

$$\Delta S_{\text{surr}} = \frac{-\Delta H_{\text{sys}}}{T} \quad [19.9]$$

For the reaction in Sample Exercise 19.5, q_{sys} is the enthalpy change for the reaction under standard conditions, ΔH° , so the changes in entropy will be standard entropy changes, ΔS° . Therefore, using the procedures described in Section 5.7, we have

$$\begin{aligned} \Delta H_{\text{rxn}}^\circ &= 2\Delta H_f^\circ[\text{NH}_3(\text{g})] - 3\Delta H_f^\circ[\text{H}_2(\text{g})] - \Delta H_f^\circ[\text{N}_2(\text{g})] \\ &= 2(-46.19 \text{ kJ}) - 3(0 \text{ kJ}) - (0 \text{ kJ}) = -92.38 \text{ kJ} \end{aligned}$$

The negative value tells us that at 298 K the formation of ammonia from $\text{H}_2(\text{g})$ and $\text{N}_2(\text{g})$ is exothermic. The surroundings absorb the heat given off by the system, which means an increase in the entropy of the surroundings:

$$\Delta S_{\text{surr}}^\circ = \frac{92.38 \text{ kJ}}{298 \text{ K}} = 0.310 \text{ kJ/K} = 310 \text{ J/K}$$

Notice that the magnitude of the entropy gained by the surroundings is greater than that lost by the system, calculated as -198.3 J/K in Sample Exercise 19.5.

The overall entropy change for the reaction is

$$\Delta S_{\text{univ}}^\circ = \Delta S_{\text{sys}}^\circ + \Delta S_{\text{surr}}^\circ = -198.3 \text{ J/K} + 310 \text{ J/K} = 112 \text{ J/K}$$

Because $\Delta S_{\text{univ}}^\circ$ is positive for any spontaneous reaction, this calculation indicates that when $\text{NH}_3(\text{g})$, $\text{H}_2(\text{g})$, and $\text{N}_2(\text{g})$ are together at 298 K in their standard states (each at 1 atm pressure), the reaction moves spontaneously toward formation of $\text{NH}_3(\text{g})$.

Keep in mind that while the thermodynamic calculations indicate that formation of ammonia is spontaneous, they do not tell us anything about the rate at which ammonia is formed. Establishing equilibrium in this system within a reasonable period requires a catalyst, as discussed in Section 15.7.

GIVE IT SOME THOUGHT

If a process is exothermic, does the entropy of the surroundings (1) always increase, (2) always decrease, or (3) sometimes increase and sometimes decrease, depending on the process?

19.5 | GIBBS FREE ENERGY

We have seen examples of endothermic processes that are spontaneous, such as the dissolution of ammonium nitrate in water. ∞ (Section 13.1) We learned in our discussion of the solution process that a spontaneous process that is endothermic must be accompanied by an increase in the entropy of the system. However, we have also encountered processes that are spontaneous and yet proceed with a *decrease* in the entropy of the system, such as the highly exothermic formation of sodium chloride from its constituent elements. ∞ (Section 8.2) Spontaneous processes that result in a decrease in the system's entropy are always exothermic. Thus, the spontaneity of a reaction seems to involve two thermodynamic concepts, enthalpy and entropy.

How can we use ΔH and ΔS to predict whether a given reaction occurring at constant temperature and pressure will be spontaneous? The means for doing so was first developed by the American mathematician J. Willard Gibbs (1839–1903). Gibbs ( FIGURE 19.15)

 **FIGURE 19.15 Josiah Willard Gibbs.** Gibbs was the first person to be awarded a Ph.D. in science from an American university (Yale, 1863). From 1871 until his death, he held the chair of mathematical physics at Yale. He developed much of the theoretical foundation that led to the development of chemical thermodynamics.

proposed a new state function, now called the **Gibbs free energy** (or just **free energy**), G , and defined as

$$G = H - TS \quad [19.10]$$

where T is the absolute temperature. For an isothermal process, the change in the free energy of the system, ΔG , is

$$\Delta G = \Delta H - T\Delta S \quad [19.11]$$

Under standard conditions, this equation becomes

$$\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ \quad [19.12]$$

To see how the state function G relates to reaction spontaneity, recall that for a reaction occurring at constant temperature and pressure

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} = \Delta S_{\text{sys}} + \left(\frac{-\Delta H_{\text{sys}}}{T} \right)$$

where we have used Equation 19.9 to substitute for ΔS_{surr} . Multiplying both sides by $-T$ gives us

$$-T\Delta S_{\text{univ}} = \Delta H_{\text{sys}} - T\Delta S_{\text{sys}} \quad [19.13]$$

Comparing Equations 19.11 and 19.13, we see that in a process occurring at constant temperature and pressure, the free-energy change, ΔG , is equal to $-T\Delta S_{\text{univ}}$. We know that for spontaneous processes, ΔS_{univ} is always positive and, therefore, $-T\Delta S_{\text{univ}}$ is always negative. Thus, the sign of ΔG provides us with extremely valuable information about the spontaneity of processes that occur at constant temperature and pressure. If both T and P are constant, the relationship between the sign of ΔG and the spontaneity of a reaction is as follows:

1. If $\Delta G < 0$, the reaction is spontaneous in the forward direction.
2. If $\Delta G = 0$, the reaction is at equilibrium.
3. If $\Delta G > 0$, the reaction in the forward direction is nonspontaneous (work must be done to make it occur) but the reverse reaction is spontaneous.

It is more convenient to use ΔG as a criterion for spontaneity than to use ΔS_{univ} because ΔG relates to the system alone and avoids the complication of having to examine the surroundings.

An analogy is often drawn between the free-energy change during a spontaneous reaction and the potential-energy change when a boulder rolls down a hill (◀ **FIGURE 19.16**). Potential energy in a gravitational field “drives” the boulder until it reaches a state of minimum potential energy in the valley. Similarly, the free energy of a chemical system decreases until it reaches a minimum value. When this minimum is reached, a state of equilibrium exists. *In any spontaneous process carried out at constant temperature and pressure, the free energy always decreases.*

To illustrate these ideas, let’s return to the Haber process for the synthesis of ammonia from nitrogen and hydrogen, which we discussed extensively in Chapter 15:

Imagine that we have a reaction vessel that allows us to maintain a constant temperature and pressure and that we have a catalyst that allows the reaction to proceed at a reasonable rate. What happens when we charge the vessel with a certain number of moles of N_2 and three times that number of moles of H_2 ? As we saw in Figure 15.3, the N_2 and H_2 react spontaneously to form NH_3 until equilibrium is achieved. Similarly, Figure 15.3 shows that if we charge the vessel with pure NH_3 , it decomposes spontaneously to N_2 and H_2 until equilibrium is reached. In each case the free energy of the system gets progressively lower and lower as the reaction moves toward equilibrium, which represents a minimum in the free energy. We illustrate these cases in ▶ **FIGURE 19.17**.

GO FIGURE

Are the processes that move a system toward equilibrium spontaneous or nonspontaneous?

▲ **FIGURE 19.16** Potential energy and free energy. An analogy is shown between the gravitational potential-energy change of a boulder rolling down a hill and the free-energy change in a spontaneous reaction.

GO FIGURE

Why are the spontaneous processes shown sometimes said to be “downhill” in free energy?

FIGURE 19.17 Free energy and approaching equilibrium. In the reaction $\text{N}_2(\text{g}) + 3 \text{H}_2(\text{g}) \rightleftharpoons 2 \text{NH}_3(\text{g})$, if the reaction mixture has too much N_2 and H_2 relative to NH_3 (left), the equilibrium lies too far to the left ($Q < K$) and NH_3 forms spontaneously. If there is too much NH_3 in the mixture (right), the equilibrium lies too far to the right ($Q > K$) and the NH_3 decomposes spontaneously into N_2 and H_2 .

GIVE IT SOME THOUGHT

What are the criteria for spontaneity

- in terms of entropy and
- in terms of free energy?

This is a good time to remind ourselves of the significance of the reaction quotient, Q , for a system that is not at equilibrium. [∞∞](#) (Section 15.6) Recall that when $Q < K$, there is an excess of reactants relative to products and the reaction proceeds spontaneously in the forward direction to reach equilibrium, as noted in Figure 19.17. When $Q > K$, the reaction proceeds spontaneously in the reverse direction. At equilibrium $Q = K$.

SAMPLE EXERCISE 19.6 Calculating Free-Energy Change from ΔH° , T , and ΔS°

Calculate the standard free-energy change for the formation of $\text{NO}(\text{g})$ from $\text{N}_2(\text{g})$ and $\text{O}_2(\text{g})$ at 298 K:

given that $\Delta H^\circ = 180.7 \text{ kJ}$ and $\Delta S^\circ = 24.7 \text{ J/K}$. Is the reaction spontaneous under these conditions?

SOLUTION

Analyze We are asked to calculate ΔG° for the indicated reaction (given ΔH° , ΔS° , and T) and to predict whether the reaction is spontaneous under standard conditions at 298 K.

Plan To calculate ΔG° , we use Equation 19.12, $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$. To determine whether the reaction is spontaneous under standard conditions, we look at the sign of ΔG° .

TABLE 19.2 • Conventions Used in Establishing Standard Free Energies

State of Matter	Standard State
Solid	Pure solid
Liquid	Pure liquid
Gas	1 atm pressure
Solution	1 M concentration
Element	$\Delta G_f^\circ = 0$ for element in standard state

Solve

$$\begin{aligned}\Delta G^\circ &= \Delta H^\circ - T\Delta S^\circ \\ &= 180.7 \text{ kJ} - (298 \text{ K})(24.7 \text{ J/K})\left(\frac{1 \text{ kJ}}{10^3 \text{ J}}\right) \\ &= 180.7 \text{ kJ} - 7.4 \text{ kJ} \\ &= 173.3 \text{ kJ}\end{aligned}$$

Because ΔG° is positive, the reaction is not spontaneous under standard conditions at 298 K.

Comment Notice that we had to convert the units of the $T\Delta S^\circ$ term to kJ so that they could be added to the ΔH° term, whose units are kJ.

PRACTICE EXERCISE

Calculate ΔG° for a reaction for which $\Delta H^\circ = 24.6 \text{ kJ}$ and $\Delta S^\circ = 132 \text{ J/K}$ at 298 K. Is the reaction spontaneous under these conditions?

Answer: $\Delta G^\circ = -14.7 \text{ kJ}$; the reaction is spontaneous.

Standard Free Energy of Formation

Recall that we defined *standard enthalpies of formation*, ΔH_f° , as the enthalpy change when a substance is formed from its elements under defined standard conditions.  (Section 5.7) We can define **standard free energies of formation**, ΔG_f° , in a similar way. As is summarized in **TABLE 19.2**, standard state means 1 atm pressure for gases, the pure solid for solids, and the pure liquid for liquids. For substances in solution, the standard state is normally a concentration of 1 M. (In very accurate work it may be necessary to make certain corrections, but we need not worry about these.)

The temperature usually chosen for purposes of tabulating data is 25 °C, but we will calculate ΔG° at other temperatures as well. Just as for the standard heats of formation, the free energies of elements in their standard states are set to zero. This arbitrary choice of a reference point has no effect on the quantity in which we are interested, which is the *difference* in free energy between reactants and products.

A listing of standard free energies of formation is given in Appendix C.

 **GIVE IT SOME THOUGHT**

What does the superscript ° indicate when associated with a thermodynamic quantity, as in ΔH° , ΔS° , or ΔG° ?

Standard free energies of formation are useful in calculating the *standard free-energy change* for chemical processes. The procedure is analogous to the calculation of ΔH° (Equation 5.31) and ΔS° (Equation 19.8):

$$\Delta G^\circ = \sum n\Delta G_f^\circ(\text{products}) - \sum m\Delta G_f^\circ(\text{reactants}) \quad [19.14]$$

SAMPLE EXERCISE 19.7 Calculating Standard Free-Energy Change from Free Energies of Formation

(a) Use data from Appendix C to calculate the standard free-energy change for the reaction $\text{P}_4(\text{g}) + 6 \text{Cl}_2(\text{g}) \longrightarrow 4 \text{PCl}_3(\text{g})$ run at 298 K.

(b) What is ΔG° for the reverse of this reaction?

SOLUTION

Analyze We are asked to calculate the free-energy change for a reaction and then to determine the free-energy change for the reverse reaction.

Plan We look up the free-energy values for the products and reactants and use Equation 19.14: We multiply the molar quantities by the coefficients in the balanced equation and subtract the total for the reactants from that for the products.

Solve

(a) $\text{Cl}_2(\text{g})$ is in its standard state, so ΔG_f° is zero for this reactant. $\text{P}_4(\text{g})$, however, is not in its standard state, so ΔG_f° is not zero for this reactant. From the balanced equation and values from Appendix C, we have

$$\begin{aligned}\Delta G_{\text{rxn}}^\circ &= 4 \Delta G_f^\circ[\text{PCl}_3(\text{g})] - \Delta G_f^\circ[\text{P}_4(\text{g})] - 6 \Delta G_f^\circ[\text{Cl}_2(\text{g})] \\ &= (4 \text{ mol})(-269.6 \text{ kJ/mol}) - (1 \text{ mol})(24.4 \text{ kJ/mol}) - 0 \\ &= -1102.8 \text{ kJ}\end{aligned}$$

That ΔG° is negative tells us that a mixture of $\text{P}_4(\text{g})$, $\text{Cl}_2(\text{g})$, and $\text{PCl}_3(\text{g})$ at 25°C , each present at a partial pressure of 1 atm, would react spontaneously in the forward direction to form more PCl_3 . Remember, however, that the value of ΔG° tells us nothing about the rate at which the reaction occurs.

(b) When we reverse the reaction, we reverse the roles of the reactants and products. Thus, reversing the reaction changes the sign of ΔG in Equation 19.14, just as reversing the reaction changes the sign of ΔH . ∞ (Section 5.4) Hence, using the result from part (a), we have

**PRACTICE EXERCISE**

Use data from Appendix C to calculate ΔG° at 298 K for the combustion of methane: $\text{CH}_4(\text{g}) + 2 \text{ O}_2(\text{g}) \longrightarrow \text{CO}_2(\text{g}) + 2 \text{ H}_2\text{O}(\text{g})$.

Answer: -800.7 kJ

SAMPLE EXERCISE 19.8 Estimating and Calculating ΔG°

In Section 5.7 we used Hess's law to calculate ΔH° for the combustion of propane gas at 298 K:

(a) Without using data from Appendix C, predict whether ΔG° for this reaction is more negative or less negative than ΔH° . (b) Use data from Appendix C to calculate ΔG° for the reaction at 298 K. Is your prediction from part (a) correct?

SOLUTION

Analyze In part (a) we must predict the value for ΔG° relative to that for ΔH° on the basis of the balanced equation for the reaction. In part (b) we must calculate the value for ΔG° and compare this value with our qualitative prediction.

Plan The free-energy change incorporates both the change in enthalpy and the change in entropy for the reaction (Equation 19.11), so under standard conditions

$$\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$$

To determine whether ΔG° is more negative or less negative than ΔH° , we need to determine the sign of the term $T\Delta S^\circ$. Because T is the absolute temperature, 298 K, it is always a positive number. We can predict the sign of ΔS° by looking at the reaction.

Solve

(a) The reactants are six molecules of gas, and the products are three molecules of gas and four molecules of liquid. Thus, the number of molecules of gas has decreased significantly during the reaction. By using the general rules discussed in Section 19.3, we expect a decrease in the number of gas molecules to lead to a decrease in the entropy of the system—the products have fewer possible microstates than the reactants. We therefore expect ΔS° and $T\Delta S^\circ$ to be negative. Because we are subtracting $T\Delta S^\circ$, which is a negative number, we predict that ΔG° is less negative than ΔH° .

(b) Using Equation 19.14 and values from Appendix C, we have

$$\begin{aligned}\Delta G^\circ &= 3\Delta G_f^\circ[\text{CO}_2(\text{g})] + 4\Delta G_f^\circ[\text{H}_2\text{O}(\text{l})] - \Delta G_f^\circ[\text{C}_3\text{H}_8(\text{g})] - 5\Delta G_f^\circ[\text{O}_2(\text{g})] \\ &= 3 \text{ mol}(-394.4 \text{ kJ/mol}) + 4 \text{ mol}(-237.13 \text{ kJ/mol}) - \\ &\quad 1 \text{ mol}(-23.47 \text{ kJ/mol}) - 5 \text{ mol}(0 \text{ kJ/mol}) = -2108 \text{ kJ}\end{aligned}$$

Notice that we have been careful to use the value of ΔG_f° for $\text{H}_2\text{O}(\text{l})$. As in calculating ΔH values, the phases of the reactants and products are important. As we predicted, ΔG° is less negative than ΔH° because of the decrease in entropy during the reaction.

PRACTICE EXERCISE

For the combustion of propane at 298 K, $\text{C}_3\text{H}_8(\text{g}) + 5 \text{ O}_2(\text{g}) \longrightarrow 3 \text{ CO}_2(\text{g}) + 4 \text{ H}_2\text{O}(\text{g})$, do you expect ΔG° to be more negative or less negative than ΔH° ?

Answer: more negative

A CLOSER LOOK

WHAT'S "FREE" ABOUT FREE ENERGY?

The Gibbs free energy is a remarkable thermodynamic quantity. Because so many chemical reactions are carried out under conditions of near-constant pressure and temperature, chemists, biochemists, and engineers use the sign and magnitude of ΔG as exceptionally useful tools in the design of chemical and biochemical reactions. We will see examples of the usefulness of ΔG throughout the remainder of this chapter and this text.

Two common questions often arise when one first learns about the Gibbs free energy: Why does the sign of ΔG tell us about the spontaneity of reactions? And what is "free" about free energy? We address these two questions here by using concepts discussed in Chapter 5 and earlier in this chapter.

In Section 19.2 we saw that the second law of thermodynamics governs the spontaneity of processes. In order to apply the second law (Equations 19.4), however, we must determine ΔS_{univ} , which is often difficult to evaluate. When T and P are constant, however, we can relate ΔS_{univ} to the changes in entropy and enthalpy of just the *system* by substituting the Equation 19.9 expression for ΔS_{surr} in Equation 19.4:

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} = \Delta S_{\text{sys}} + \left(\frac{-\Delta H_{\text{sys}}}{T} \right) \quad [19.15]$$

(constant T, P)

Thus, at constant temperature and pressure, the second law becomes

$$\text{Reversible process: } \Delta S_{\text{univ}} = \Delta S_{\text{sys}} - \frac{\Delta H_{\text{sys}}}{T} = 0 \quad [19.16]$$

$$\text{Irreversible process: } \Delta S_{\text{univ}} = \Delta S_{\text{sys}} - \frac{\Delta H_{\text{sys}}}{T} > 0$$

(constant T, P)

Now we can see the relationship between ΔG_{sys} (which we call simply ΔG) and the second law. From Equation 19.11 we know that $\Delta G = \Delta H_{\text{sys}} - T\Delta S_{\text{sys}}$. If we multiply Equations 19.16 by $-T$ and rearrange, we reach the following conclusion:

$$\text{Reversible process: } \Delta G = \Delta H_{\text{sys}} - T\Delta S_{\text{sys}} = 0 \quad [19.17]$$

$$\text{Irreversible process: } \Delta G = \Delta H_{\text{sys}} - T\Delta S_{\text{sys}} < 0$$

(constant T, P)

Equations 19.17 allow us to use the sign of ΔG to conclude whether a reaction is spontaneous, nonspontaneous, or at equilibrium. When $\Delta G < 0$, a process is irreversible and, therefore, spontaneous. When $\Delta G = 0$, the process is reversible and, therefore, at equilibrium. If a process has $\Delta G > 0$, then the reverse process will have $\Delta G < 0$; thus, the process as written is nonspontaneous but its reverse reaction will be irreversible and spontaneous.

The magnitude of ΔG is also significant. A reaction for which ΔG is large and negative, such as the burning of gasoline, is much more capable of doing work on the surroundings than is a reaction for which ΔG is small and negative, such as ice melting at room temperature. In fact, thermodynamics tells us that *the change in free energy for a process, ΔG , equals the maximum useful work that can be done by the system on its surroundings in a spontaneous process occurring at constant temperature and pressure:*

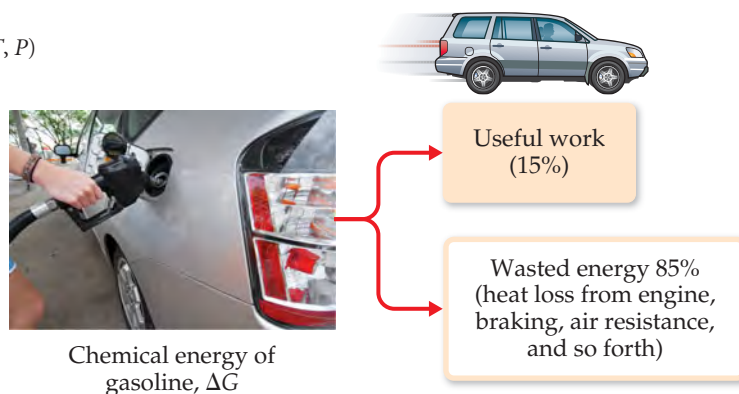

$$\Delta G = -w_{\text{max}} \quad [19.18]$$

(Remember our sign convention from Table 5.1: Work done *by* a system is negative.) In other words, ΔG gives the theoretical limit to how much work can be done by a process.

The relationship in Equation 19.18 explains why ΔG is called *free* energy—it is the portion of the energy change of a spontaneous reaction that is free to do useful work. The remainder of the energy enters the environment as heat. For example, the theoretical maximum work obtained for the combustion of gasoline is given by the value of ΔG for the combustion reaction. On average, standard internal combustion engines are inefficient in utilizing this potential work—more than 60% of the potential work is lost (primarily as heat) in converting the chemical energy of the gasoline to mechanical energy to move the vehicle (▼ FIGURE 19.18). When other losses are considered—idling time, braking, aerodynamic drag, and so forth—only about 15% of the potential work from the gasoline is used to move the car. Advances in automobile design—such as hybrid technology, efficient diesel engines, and new lightweight materials—have the potential to increase the percentage of useful work obtained from the gasoline.

For nonspontaneous processes ($\Delta G > 0$), the free-energy change is a measure of the *minimum* amount of work that must be done to cause the process to occur. In actuality, we always need to do more than this theoretical minimum amount because of the inefficiencies in the way the changes occur.

► **FIGURE 19.18** Energy losses in automobiles. Very little of the chemical energy of gasoline is actually used as work to move a typical automobile.

19.6 FREE ENERGY AND TEMPERATURE

Tabulations of ΔG_f° , such as those in Appendix C, make it possible to calculate ΔG° for reactions at the standard temperature of 25 °C, but we are often interested in examining reactions at other temperatures. To see how ΔG is affected by temperature, let's look again at Equation 19.11:

$$\Delta G = \Delta H - T\Delta S = \underset{\substack{\text{Enthalpy} \\ \text{term}}}{\Delta H} + \underset{\substack{\text{Entropy} \\ \text{term}}}{(-T\Delta S)}$$

Notice that we have written the expression for ΔG as a sum of two contributions, an enthalpy term, ΔH , and an entropy term, $-T\Delta S$. Because the value of $-T\Delta S$ depends directly on the absolute temperature T , ΔG varies with temperature. We know that the enthalpy term, ΔH , can be either positive or negative and that T is positive at all temperatures other than absolute zero. The entropy term, $-T\Delta S$, can also be positive or negative. When ΔS is positive, which means the final state has greater randomness (a greater number of microstates) than the initial state, the term $-T\Delta S$ is negative. When ΔS is negative, $-T\Delta S$ is positive.

The sign of ΔG , which tells us whether a process is spontaneous, depends on the signs and magnitudes of ΔH and $-T\Delta S$. The various combinations of ΔH and $-T\Delta S$ signs are given in **TABLE 19.3**.

Note in Table 19.3 that when ΔH and $-T\Delta S$ have opposite signs, the sign of ΔG depends on the magnitudes of these two terms. In these instances temperature is an important consideration. Generally, ΔH and ΔS change very little with temperature. However, the value of T directly affects the magnitude of $-T\Delta S$. As the temperature increases, the magnitude of $-T\Delta S$ increases, and this term becomes relatively more important in determining the sign and magnitude of ΔG .

As an example, let's consider once more the melting of ice to liquid water at 1 atm:

This process is endothermic, which means that ΔH is positive. Because the entropy increases during the process, ΔS is positive, which makes $-T\Delta S$ negative. At temperatures below 0 °C (273 K), the magnitude of ΔH is greater than that of $-T\Delta S$. Hence, the positive enthalpy term dominates, and ΔG is positive. This positive value of ΔG means that ice melting is not spontaneous at $T < 0$ °C, just as our everyday experience tells us; rather, the reverse process, the freezing of liquid water into ice, is spontaneous at these temperatures.

What happens at temperatures greater than 0 °C? As T increases, so does the magnitude of $-T\Delta S$. When $T > 0$ °C, the magnitude of $-T\Delta S$ is greater than the magnitude of ΔH , which means that the $-T\Delta S$ term dominates and ΔG is negative. The negative value of ΔG tells us that ice melting is spontaneous at $T > 0$ °C.

At the normal melting point of water, $T = 0$ °C, the two phases are in equilibrium. Recall that $\Delta G = 0$ at equilibrium; at $T = 0$ °C, ΔH and $-T\Delta S$ are equal in magnitude and opposite in sign, so they cancel and give $\Delta G = 0$.

TABLE 19.3 • How Signs of ΔH and ΔS Affect Reaction Spontaneity

ΔH	ΔS	$-T\Delta S$	$\Delta G = \Delta H - T\Delta S$	Reaction Characteristics	Example
–	+	–	–	Spontaneous at all temperatures	$2 \text{O}_3(g) \longrightarrow 3 \text{O}_2(g)$
+	–	+	+	Nonspontaneous at all temperatures	$3 \text{O}_2(g) \longrightarrow 2 \text{O}_3(g)$
–	–	+	+ or –	Spontaneous at low T ; nonspontaneous at high T	$\text{H}_2\text{O}(l) \longrightarrow \text{H}_2\text{O}(s)$
+	+	–	+ or –	Spontaneous at high T ; nonspontaneous at low T	$\text{H}_2\text{O}(s) \longrightarrow \text{H}_2\text{O}(l)$

GIVE IT SOME THOUGHT

The normal boiling point of benzene is 80 °C. At 100 °C and 1 atm, which term is greater in magnitude for the vaporization of benzene, ΔH or $T\Delta S$?

Our discussion of the temperature dependence of ΔG is also relevant to standard free-energy changes. We can calculate the values of ΔH° and ΔS° at 298 K from the data in Appendix C. If we assume that these values do not change with temperature, we can then use Equation 19.12 to estimate ΔG° at temperatures other than 298 K.

SAMPLE EXERCISE 19.9 Determining the Effect of Temperature on Spontaneity

The Haber process for the production of ammonia involves the equilibrium

Assume that ΔH° and ΔS° for this reaction do not change with temperature. (a) Predict the direction in which ΔG° for the reaction changes with increasing temperature. (b) Calculate ΔG° at 25 °C and 500 °C.

SOLUTION

Analyze In part (a) we are asked to predict the direction in which ΔG° changes as temperature increases. In part (b) we need to determine ΔG° for the reaction at two temperatures.

Plan We can answer part (a) by determining the sign of ΔS for the reaction and then using that information to analyze Equation 19.12. In part (b) we first calculate ΔH° and ΔS° for the reaction using data in Appendix C and then use Equation 19.12 to calculate ΔG° .

Solve

(a) The temperature dependence of ΔG° comes from the entropy term in Equation 19.12, $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$. We expect ΔS° for this reaction to be negative because the number of molecules of gas is smaller in the products. Because ΔS° is negative, $-T\Delta S^\circ$ is positive and increases with increasing temperature. As a result, ΔG° becomes less negative (or more positive) with increasing temperature. Thus, the driving force for the production of NH_3 becomes smaller with increasing temperature.

(b) We calculated ΔH° for this reaction in Sample Exercise 15.14 and ΔS° in Sample Exercise 19.5: $\Delta H^\circ = -92.38 \text{ kJ}$ and $\Delta S^\circ = -198.3 \text{ J/K}$. If we assume that these values do not change with temperature, we can calculate ΔG° at any temperature by using Equation 19.12. At $T = 25 \text{ }^\circ\text{C} = 298 \text{ K}$, we have

$$\begin{aligned} \Delta G^\circ &= -92.38 \text{ kJ} - (298 \text{ K})(-198.3 \text{ J/K})\left(\frac{1 \text{ kJ}}{1000 \text{ J}}\right) \\ &= -92.38 \text{ kJ} + 59.1 \text{ kJ} = -33.3 \text{ kJ} \end{aligned}$$

At $T = 500 \text{ }^\circ\text{C} = 773 \text{ K}$, we have

$$\begin{aligned} \Delta G^\circ &= -92.38 \text{ kJ} - (773 \text{ K})\left(-198.3 \frac{\text{J}}{\text{K}}\right)\left(\frac{1 \text{ kJ}}{1000 \text{ J}}\right) \\ &= -92.38 \text{ kJ} + 153 \text{ kJ} = 61 \text{ kJ} \end{aligned}$$

Notice that we had to convert the units of $-T\Delta S^\circ$ to kJ in both calculations so that this term can be added to the ΔH° term, which has units of kJ.

Comment Increasing the temperature from 298 K to 773 K changes ΔG° from -33.3 kJ to $+61 \text{ kJ}$. Of course, the result at 773 K assumes that ΔH° and ΔS° do not change with temperature. Although these values do change slightly with temperature, the result at 773 K should be a reasonable approximation.

The positive increase in ΔG° with increasing T agrees with our prediction in part (a). Our result indicates that in a mixture of $\text{N}_2(\text{g})$, $\text{H}_2(\text{g})$, and $\text{NH}_3(\text{g})$, each present at a partial pressure of 1 atm, the $\text{N}_2(\text{g})$ and $\text{H}_2(\text{g})$ react spontaneously at 298 K to form more $\text{NH}_3(\text{g})$. At 773 K, the positive value of ΔG° tells us that the reverse reaction is spontaneous. Thus, when the mixture of these gases, each at a partial pressure of 1 atm, is heated to 773 K, some of the $\text{NH}_3(\text{g})$ spontaneously decomposes into $\text{N}_2(\text{g})$ and $\text{H}_2(\text{g})$.

PRACTICE EXERCISE

(a) Using standard enthalpies of formation and standard entropies in Appendix C, calculate ΔH° and ΔS° at 298 K for the reaction $2 \text{SO}_2(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 2 \text{SO}_3(\text{g})$. (b) Use your values from part (a) to estimate ΔG° at 400 K.

Answers: (a) $\Delta H^\circ = -196.6 \text{ kJ}$, $\Delta S^\circ = -189.6 \text{ J/K}$; (b) $\Delta G^\circ = -120.8 \text{ kJ}$

19.7 FREE ENERGY AND THE EQUILIBRIUM CONSTANT

In Section 19.5 we saw a special relationship between ΔG and equilibrium: For a system at equilibrium, $\Delta G = 0$. We have also seen how to use tabulated thermodynamic data to calculate values of the standard free-energy change, ΔG° . In this final section, we learn two more ways in which we can use free energy to analyze chemical reactions: using ΔG° to calculate ΔG under *nonstandard* conditions and relating the values of ΔG° and K for a reaction.

Free Energy Under Nonstandard Conditions

The set of standard conditions for which ΔG° values pertain is given in Table 19.2. Most chemical reactions occur under nonstandard conditions. For any chemical process, the relationship between the free-energy change under standard conditions, ΔG° , and the free-energy change under any other conditions, ΔG , is given by

$$\Delta G = \Delta G^\circ + RT \ln Q \quad [19.19]$$

In this equation R is the ideal-gas constant, 8.314 J/mol-K; T is the absolute temperature; and Q is the reaction quotient for the reaction mixture of interest. ∞ (Section 15.6) Under standard conditions, the concentrations of all the reactants and products are equal to 1. Thus, under standard conditions $Q = 1$, $\ln Q = 0$, and Equation 19.19 reduces to $\Delta G = \Delta G^\circ$ under standard conditions, as it should.

SAMPLE EXERCISE 19.10 Relating ΔG to a Phase Change at Equilibrium

- (a) Write the chemical equation that defines the normal boiling point of liquid carbon tetrachloride, $\text{CCl}_4(l)$.
 (b) What is the value of ΔG° for the equilibrium in part (a)? (c) Use data from Appendix C and Equation 19.12 to estimate the normal boiling point of CCl_4 .

SOLUTION

Analyze (a) We must write a chemical equation that describes the physical equilibrium between liquid and gaseous CCl_4 at the normal boiling point. (b) We must determine the value of ΔG° for CCl_4 , in equilibrium with its vapor at the normal boiling point. (c) We must estimate the normal boiling point of CCl_4 , based on available thermodynamic data.

Plan (a) The chemical equation is the change of state from liquid to gas. For (b), we need to analyze Equation 19.19 at equilibrium ($\Delta G = 0$), and for (c) we can use Equation 19.12 to calculate T when $\Delta G = 0$.

Solve

(a) The normal boiling point is the temperature at which a pure liquid is in equilibrium with its vapor at a pressure of 1 atm:

(b) At equilibrium, $\Delta G = 0$. In any normal boiling-point equilibrium, both liquid and vapor are in their standard state of pure liquid and vapor at 1 atm (Table 19.2). Consequently, $Q = 1$, $\ln Q = 0$, and $\Delta G = \Delta G^\circ$ for this process. We conclude that $\Delta G^\circ = 0$ for the equilibrium representing the normal boiling point of any liquid. (We would also find that $\Delta G^\circ = 0$ for the equilibria relevant to normal melting points and normal sublimation points.)

(c) Combining Equation 19.12 with the result from part (b), we see that the equality at the normal boiling point, T_b , of $\text{CCl}_4(l)$ (or any other pure liquid) is

Solving the equation for T_b , we obtain

$$\Delta G^\circ = \Delta H^\circ - T_b \Delta S^\circ = 0$$

$$T_b = \Delta H^\circ / \Delta S^\circ$$

Strictly speaking, we need the values of ΔH° and ΔS° for the $\text{CCl}_4(l)$ – $\text{CCl}_4(g)$ equilibrium at the normal boiling point to do this calculation. However, we can *estimate* the boiling point by using the values of ΔH° and ΔS° for CCl_4 at 298 K, which we obtain from Appendix C and Equations 5.31 and 19.8:

$$\Delta H^\circ = (1 \text{ mol})(-106.7 \text{ kJ/mol}) - (1 \text{ mol})(-139.3 \text{ kJ/mol}) = +32.6 \text{ kJ}$$

$$\Delta S^\circ = (1 \text{ mol})(309.4 \text{ J/mol-K}) - (1 \text{ mol})(214.4 \text{ J/mol-K}) = +95.0 \text{ J/K}$$

As expected, the process is endothermic ($\Delta H > 0$) and produces a gas, thus increasing the entropy ($\Delta S > 0$). We now use these values to estimate T_b for $\text{CCl}_4(l)$:

$$T_b = \frac{\Delta H^\circ}{\Delta S^\circ} = \left(\frac{32.6 \text{ kJ}}{95.0 \text{ J/K}} \right) \left(\frac{1000 \text{ J}}{1 \text{ kJ}} \right) = 343 \text{ K} = 70^\circ \text{C}$$

Note that we have used the conversion factor between joules and kilojoules to make the units of ΔH° and ΔS° match.

Check The experimental normal boiling point of $\text{CCl}_4(l)$ is 76.5°C . The small deviation of our estimate from the experimental value is due to the assumption that ΔH° and ΔS° do not change with temperature.

PRACTICE EXERCISE

Use data in Appendix C to estimate the normal boiling point, in K, for elemental bromine, $\text{Br}_2(l)$. (The experimental value is given in Figure 11.5.)

Answer: 330 K

When the concentrations of reactants and products are nonstandard, we must calculate Q in order to determine ΔG . We illustrate how this is done in Sample Exercise 19.11. At this stage in our discussion, therefore, it becomes important to note the units used to calculate Q when using Equation 19.19. The convention used for standard states is used when applying this equation: In determining the value of Q , the concentrations of gases are always expressed as partial pressures in atmospheres and solutes are expressed as their concentrations in molarities.

SAMPLE EXERCISE 19.11 Calculating the Free-Energy Change under Nonstandard Conditions

Calculate ΔG at 298 K for a mixture of 1.0 atm N_2 , 3.0 atm H_2 , and 0.50 atm NH_3 being used in the Haber process:

SOLUTION

Analyze We are asked to calculate ΔG under nonstandard conditions.

Plan We can use Equation 19.19 to calculate ΔG . Doing so requires that we calculate the value of the reaction quotient Q for the specified partial pressures, for which we use the partial-pressures form of Equation 15.23: $Q = [\text{D}]^d[\text{E}]^e/[\text{A}]^a[\text{B}]^b$. We then use a table of standard free energies of formation to evaluate ΔG° .

Solve The partial-pressures form of Equation 15.23 gives

$$Q = \frac{P_{\text{NH}_3}^2}{P_{\text{N}_2} P_{\text{H}_2}^3} = \frac{(0.50)^2}{(1.0)(3.0)^3} = 9.3 \times 10^{-3}$$

In Sample Exercise 19.9 we calculated $\Delta G^\circ = -33.3 \text{ kJ}$ for this reaction. We will have to change the units of this quantity in applying Equation 19.19, however. For the units in Equation 19.19 to work out, we will use kJ/mol as our units for ΔG° , where “per mole” means “per mole of the reaction as written.” Thus, $\Delta G^\circ = -33.3 \text{ kJ/mol}$ implies per 1 mol of N_2 , per 3 mol of H_2 , and per 2 mol of NH_3 .

We now use Equation 19.19 to calculate ΔG for these nonstandard conditions:

$$\begin{aligned} \Delta G &= \Delta G^\circ + RT \ln Q \\ &= (-33.3 \text{ kJ/mol}) + (8.314 \text{ J/mol}\cdot\text{K})(298 \text{ K})(1 \text{ kJ}/1000 \text{ J}) \ln(9.3 \times 10^{-3}) \\ &= (-33.3 \text{ kJ/mol}) + (-11.6 \text{ kJ/mol}) = -44.9 \text{ kJ/mol} \end{aligned}$$

Comment We see that ΔG becomes more negative as the pressures of N_2 , H_2 , and NH_3 are changed from 1.0 atm (standard conditions, ΔG°) to 1.0 atm, 3.0 atm, and 0.50 atm, respectively. The larger negative value for ΔG indicates a larger “driving force” to produce NH_3 .

We would make the same prediction based on Le Châtelier’s principle. ∞ (Section 15.7) Relative to standard conditions, we have increased the pressure of a reactant (H_2) and decreased the pressure of the product (NH_3). Le Châtelier’s principle predicts that both changes shift the reaction to the product side, thereby forming more NH_3 .

PRACTICE EXERCISE

Calculate ΔG at 298 K for the Haber reaction if the reaction mixture consists of 0.50 atm N_2 , 0.75 atm H_2 , and 2.0 atm NH_3 .

Answer: -26.0 kJ/mol

Relationship Between ΔG° and K

We can now use Equation 19.19 to derive the relationship between ΔG° and the equilibrium constant, K . At equilibrium, $\Delta G = 0$ and $Q = K$. Thus, at equilibrium, Equation 19.19 transforms as follows:

$$\begin{aligned}\Delta G &= \Delta G^\circ + RT \ln Q \\ 0 &= \Delta G^\circ + RT \ln K \\ \Delta G^\circ &= -RT \ln K\end{aligned}\quad [19.20]$$

By solving Equation 19.20 for K , we obtain an expression that allows us to calculate K if we know the value of ΔG° :

$$\begin{aligned}\ln K &= \frac{\Delta G^\circ}{-RT} \\ K &= e^{-\Delta G^\circ/RT}\end{aligned}\quad [19.21]$$

As usual, we must be careful in our choice of units. In Equations 19.20 and 19.21 we again express ΔG° in kJ/mol. In the equilibrium-constant expression, we use atmospheres for gas pressures, molarities for solutions, and solids, liquids, and solvents do not appear in the expression. ∞ (Section 15.4) Thus, the equilibrium constant is K_p for gas-phase reactions and K_c for reactions in solution. ∞ (Section 15.2)

From Equation 19.20 we see that if ΔG° is negative, $\ln K$ must be positive, which means $K > 1$. Therefore, the more negative ΔG° is, the larger K is. Conversely, if ΔG° is positive, $\ln K$ is negative, which means $K < 1$. \blacktriangleright **TABLE 19.4** summarizes these relationships.

TABLE 19.4 • Relationship between ΔG° and K at 298 K

ΔG° (kJ/mol)	K
+200	8.7×10^{-36}
+100	3.0×10^{-18}
+50	1.7×10^{-9}
+10	1.8×10^{-2}
+1.0	6.7×10^{-1}
0	1.0
-1.0	1.5
-10	5.7×10^1
-50	5.8×10^8
-100	3.4×10^{17}
-200	1.1×10^{35}

SAMPLE EXERCISE 19.12 Calculating an Equilibrium Constant from ΔG°

The standard free-energy change for the Haber process at 25 °C was obtained in Sample Exercise 19.9 for the Haber reaction:

Use this value of ΔG° to calculate the equilibrium constant for the process at 25 °C.

SOLUTION

Analyze We are asked to calculate K for a reaction, given ΔG° .

Plan We can use Equation 19.21 to calculate K .

Solve Remembering to use the absolute temperature for T in Equation 19.21 and the form of R that matches our units, we have

$$K = e^{-\Delta G^\circ/RT} = e^{-(-33,300 \text{ J/mol})/(8.314 \text{ J/mol}\cdot\text{K})(298 \text{ K})} = e^{13.4} = 7 \times 10^5$$

Comment This is a large equilibrium constant, which indicates that the product, NH_3 , is greatly favored in the equilibrium mixture at 25 °C. The equilibrium constants for the Haber reaction at temperatures in the range 300 °C to 600 °C, given in Table 15.2, are much smaller than the value at 25 °C. Clearly, a low-temperature equilibrium favors the production of ammonia more than a high-temperature one. Nevertheless, the Haber process is carried out at high temperatures because the reaction is extremely slow at room temperature.

Remember Thermodynamics can tell us the direction and extent of a reaction but tells us nothing about the rate at which it will occur. If a catalyst were found that would permit the reaction to proceed at a rapid rate at room temperature, high pressures would not be needed to force the equilibrium toward NH_3 .

PRACTICE EXERCISE

Use data from Appendix C to calculate ΔG° and K at 298 K for the reaction $\text{H}_2(\text{g}) + \text{Br}_2(\text{l}) \rightleftharpoons 2 \text{HBr}(\text{g})$.

Answer: $\Delta G^\circ = -106.4 \text{ kJ/mol}$, $K = 4 \times 10^{18}$

CHEMISTRY AND LIFE

DRIVING NONSPONTANEOUS REACTIONS

Many desirable chemical reactions, including a large number that are central to living systems, are nonspontaneous as written. For example, consider the extraction of copper metal from the mineral *chalcocite*, which contains Cu_2S . The decomposition of Cu_2S to its elements is nonspontaneous:

Because ΔG° is very positive, we cannot obtain $\text{Cu}(s)$ directly via this reaction. Instead, we must find some way to “do work” on the reaction to force it to occur as we wish. We can do this by coupling the reaction to another one so that the overall reaction is spontaneous. For example, we can envision the $\text{S}(s)$ reacting with $\text{O}_2(g)$ to form $\text{SO}_2(g)$:

By coupling these reactions, we can extract much of the copper metal via a spontaneous reaction:

In essence, we have used the spontaneous reaction of $\text{S}(s)$ with $\text{O}_2(g)$ to provide the free energy needed to extract the copper metal from the mineral.

Biological systems employ the same principle of using spontaneous reactions to drive nonspontaneous ones. Many of the

biochemical reactions that are essential for the formation and maintenance of highly ordered biological structures are not spontaneous. These necessary reactions are made to occur by coupling them with spontaneous reactions that release energy. The metabolism of food is the usual source of the free energy needed to do the work of maintaining biological systems. For example, complete oxidation of the sugar *glucose*, $\text{C}_6\text{H}_{12}\text{O}_6$, to CO_2 and H_2O yields substantial free energy:

This energy can be used to drive nonspontaneous reactions in the body. However, a means is necessary to transport the energy released by glucose metabolism to the reactions that require energy. One way, shown in ▼ FIGURE 19.19, involves the interconversion of adenosine triphosphate (ATP) and adenosine diphosphate (ADP), molecules that are related to the building blocks of nucleic acids. The conversion of ATP to ADP releases free energy ($\Delta G^\circ = -30.5 \text{ kJ}$) that can be used to drive other reactions.

In the human body the metabolism of glucose occurs via a complex series of reactions, most of which release free energy. The free energy released during these steps is used in part to reconvert lower-energy ADP back to higher-energy ATP. Thus, the ATP–ADP interconversions are used to store energy during metabolism and to release it as needed to drive nonspontaneous reactions in the body. If you take a course in biochemistry, you will have the opportunity to learn more about the remarkable sequence of reactions used to transport free energy throughout the human body.

RELATED EXERCISES: 19.102 and 19.103

► FIGURE 19.19 Schematic representation of free-energy changes during cell metabolism. The oxidation of glucose to CO_2 and H_2O produces free energy that is then used to convert ADP into the more energetic ATP. The ATP is then used, as needed, as an energy source to drive nonspontaneous reactions, such as the conversion of simple molecules into more complex cell constituents.

SAMPLE INTEGRATIVE EXERCISE Putting Concepts Together

Consider the simple salts NaCl(s) and AgCl(s). We will examine the equilibria in which these salts dissolve in water to form aqueous solutions of ions:

(a) Calculate the value of ΔG° at 298 K for each of the preceding reactions. (b) The two values from part (a) are very different. Is this difference primarily due to the enthalpy term or the entropy term of the standard free-energy change? (c) Use the values of ΔG° to calculate the K_{sp} values for the two salts at 298 K. (d) Sodium chloride is considered a soluble salt, whereas silver chloride is considered insoluble. Are these descriptions consistent with the answers to part (c)? (e) How will ΔG° for the solution process of these salts change with increasing T ? What effect should this change have on the solubility of the salts?

SOLUTION

(a) We will use Equation 19.14 along with ΔG_f° values from Appendix C to calculate the $\Delta G_{\text{soln}}^\circ$ values for each equilibrium. (As we did in Section 13.1, we use the subscript “soln” to indicate that these are thermodynamic quantities for the formation of a solution.) We find

$$\begin{aligned}\Delta G_{\text{soln}}^\circ(\text{NaCl}) &= (-261.9 \text{ kJ/mol}) + (-131.2 \text{ kJ/mol}) - (-384.0 \text{ kJ/mol}) \\ &= -9.1 \text{ kJ/mol}\end{aligned}$$

$$\begin{aligned}\Delta G_{\text{soln}}^\circ(\text{AgCl}) &= (+77.11 \text{ kJ/mol}) + (-131.2 \text{ kJ/mol}) - (-109.70 \text{ kJ/mol}) \\ &= +55.6 \text{ kJ/mol}\end{aligned}$$

(b) We can write $\Delta G_{\text{soln}}^\circ$ as the sum of an enthalpy term, $\Delta H_{\text{soln}}^\circ$, and an entropy term, $-T\Delta S_{\text{soln}}^\circ$: $\Delta G_{\text{soln}}^\circ = \Delta H_{\text{soln}}^\circ + (-T\Delta S_{\text{soln}}^\circ)$. We can calculate the values of $\Delta H_{\text{soln}}^\circ$ and $\Delta S_{\text{soln}}^\circ$ by using Equations 5.31 and 19.8. We can then calculate $-T\Delta S_{\text{soln}}^\circ$ at $T = 298 \text{ K}$. All these calculations are now familiar to us. The results are summarized in the following table:

Salt	$\Delta H_{\text{soln}}^\circ$	$\Delta S_{\text{soln}}^\circ$	$T\Delta S_{\text{soln}}^\circ$
NaCl	+3.6 kJ/mol	+43.2 kJ/mol-K	-12.9 kJ/mol
AgCl	+65.7 kJ/mol	+34.3 kJ/mol-K	-10.2 kJ/mol

The entropy terms for the solution of the two salts are very similar. That seems sensible because each solution process should lead to a similar increase in randomness as the salt dissolves, forming hydrated ions. ∞ (Section 13.1) In contrast, we see a very large difference in the enthalpy term for the solution of the two salts. The difference in the values of $\Delta G_{\text{soln}}^\circ$ is dominated by the difference in the values of $\Delta H_{\text{soln}}^\circ$.

(c) The solubility product, K_{sp} , is the equilibrium constant for the solution process. ∞ (Section 17.4) As such, we can relate K_{sp} directly to $\Delta G_{\text{soln}}^\circ$ by using Equation 19.21:

$$K_{sp} = e^{-\Delta G_{\text{soln}}^\circ/RT}$$

We can calculate the K_{sp} values in the same way we applied Equation 19.21 in Sample Exercise 19.12. We use the $\Delta G_{\text{soln}}^\circ$ values we obtained in part (a), remembering to convert them from kJ/mol to J/mol:

$$\text{NaCl: } K_{sp} = [\text{Na}^+(aq)][\text{Cl}^-(aq)] = e^{-(-9100)/[(8.314)(298)]} = e^{+3.7} = 40$$

$$\text{AgCl: } K_{sp} = [\text{Ag}^+(aq)][\text{Cl}^-(aq)] = e^{-(+55,600)/[(8.314)(298)]} = e^{-22.4} = 1.9 \times 10^{-10}$$

The value calculated for the K_{sp} of AgCl is very close to that listed in Appendix D.

(d) A soluble salt is one that dissolves appreciably in water. ∞ (Section 4.2) The K_{sp} value for NaCl is greater than 1, indicating that NaCl dissolves to a great extent. The K_{sp} value for AgCl is very small, indicating that very little dissolves in water. Silver chloride should indeed be considered an insoluble salt.

(e) As we expect, the solution process has a positive value of ΔS for both salts (see the table in part b). As such, the entropy term of the free-energy change, $-T\Delta S_{\text{soln}}^\circ$, is negative. If we assume that $\Delta H_{\text{soln}}^\circ$ and $\Delta S_{\text{soln}}^\circ$ do not change much with temperature, then an increase in T will serve to make $\Delta G_{\text{soln}}^\circ$ more negative. Thus, the driving force for dissolution of the salts will increase with increasing T , and we therefore expect the solubility of the salts to increase with increasing T . In Figure 13.18 we see that the solubility of NaCl (and that of nearly any other salt) increases with increasing temperature. ∞ (Section 13.3)

CHAPTER SUMMARY AND KEY TERMS

SECTION 19.1 Most reactions and chemical processes have an inherent directionality: They are **spontaneous** in one direction and nonspontaneous in the reverse direction. The spontaneity of a process is related to the thermodynamic path the system takes from the initial state to the final state. In a **reversible process**, both the system and its surroundings can be restored to their original state by exactly reversing the change. In an **irreversible process** the system cannot return to its original state without there being a permanent change in the surroundings. Any spontaneous process is irreversible. A process that occurs at a constant temperature is said to be **isothermal**.

SECTION 19.2 The spontaneous nature of processes is related to a thermodynamic state function called **entropy**, denoted S . For a process that occurs at constant temperature, the entropy change of the system is given by the heat absorbed by the system along a reversible path, divided by the temperature: $\Delta S = q_{\text{rev}}/T$. The way entropy controls the spontaneity of processes is given by the **second law of thermodynamics**, which governs the change in the entropy of the universe, $\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}}$. The second law states that in a reversible process $\Delta S_{\text{univ}} = 0$; in an irreversible (spontaneous) process $\Delta S_{\text{univ}} > 0$. Entropy values are usually expressed in units of joules per kelvin, J/K.

SECTION 19.3 A particular combination of motions and locations of the atoms and molecules of a system at a particular instant is called a **microstate**. The entropy of a system is a measure of its randomness or disorder. The entropy is related to the number of microstates, W , corresponding to the state of the system: $S = k \ln W$. Molecules can undergo three kinds of motion: In **translational motion** the entire molecule moves in space. Molecules can also undergo **vibrational motion**, in which the atoms of the molecule move toward and away from one another in periodic fashion, and **rotational motion**, in which the entire molecule spins like a top. The number of available microstates, and therefore the entropy, increases with an increase in volume, temperature, or motion of molecules because any of these changes increases the possible motions and locations of the molecules. As a result, entropy generally increases when liquids or solutions are formed from solids, gases are formed from either solids or liquids, or the number of molecules of gas increases during a chemical reaction. The **third law of thermodynamics** states that the entropy of a pure crystalline solid at 0 K is zero.

SECTION 19.4 The third law allows us to assign entropy values for substances at different temperatures. Under standard conditions the entropy of a mole of a substance is called its **standard molar entropy**, denoted S° . From tabulated values of S° , we can calculate the entropy change for any process under standard conditions. For an isothermal process, the entropy change in the surroundings is equal to $-\Delta H/T$.

SECTION 19.5 The **Gibbs free energy** (or just **free energy**), G , is a thermodynamic state function that combines the two state functions enthalpy and entropy: $G = H - TS$. For processes that occur at constant temperature, $\Delta G = \Delta H - T\Delta S$. For a process occurring at constant temperature and pressure, the sign of ΔG relates to the spontaneity of the process. When ΔG is negative, the process is spontaneous. When ΔG is positive, the process is nonspontaneous but the reverse process is spontaneous. At equilibrium the process is reversible and ΔG is zero. The free energy is also a measure of the maximum useful work that can be performed by a system in a spontaneous process. The standard free-energy change, ΔG° , for any process can be calculated from tabulations of **standard free energies of formation**, ΔG_f° , which are defined in a fashion analogous to standard enthalpies of formation, ΔH_f° . The value of ΔG_f° for a pure element in its standard state is defined to be zero.

SECTIONS 19.6 AND 19.7 The values of ΔH and ΔS generally do not vary much with temperature. Therefore, the dependence of ΔG with temperature is governed mainly by the value of T in the expression $\Delta G = \Delta H - T\Delta S$. The entropy term $-T\Delta S$ has the greater effect on the temperature dependence of ΔG and, hence, on the spontaneity of the process. For example, a process for which $\Delta H > 0$ and $\Delta S > 0$, such as the melting of ice, can be nonspontaneous ($\Delta G > 0$) at low temperatures and spontaneous ($\Delta G < 0$) at higher temperatures. Under nonstandard conditions ΔG is related to ΔG° and the value of the reaction quotient, Q : $\Delta G = \Delta G^\circ + RT \ln Q$. At equilibrium ($\Delta G = 0$, $Q = K$), $\Delta G^\circ = -RT \ln K$. Thus, the standard free-energy change is directly related to the equilibrium constant for the reaction. This relationship expresses the temperature dependence of equilibrium constants.

KEY SKILLS

- Understand the meaning of spontaneous process, reversible process, irreversible process, and isothermal process. (Section 19.1)
- State the second law of thermodynamics. (Section 19.2)
- Explain how the entropy of a system is related to the number of possible microstates. (Section 19.3)
- Describe the kinds of molecular motion that a molecule can possess. (Section 19.3)
- Predict the sign of ΔS for physical and chemical processes. (Section 19.3)
- State the third law of thermodynamics. (Section 19.3)
- Calculate standard entropy changes for a system from standard molar entropies. (Section 19.4)
- Calculate entropy changes in the surroundings for isothermal processes. (Section 19.4)
- Calculate the Gibbs free energy from the enthalpy change and entropy change at a given temperature. (Section 19.5)
- Use free-energy changes to predict whether reactions are spontaneous. (Section 19.5)
- Calculate standard free-energy changes using standard free energies of formation. (Section 19.5)
- Predict the effect of temperature on spontaneity given ΔH and ΔS . (Section 19.6)
- Calculate ΔG under nonstandard conditions. (Section 19.7)
- Relate ΔG° and equilibrium constant. (Section 19.7)

KEY EQUATIONS

- $\Delta S = \frac{q_{\text{rev}}}{T}$ (constant T) [19.2] Relating entropy change to the heat absorbed or released in a reversible process
- $\left. \begin{array}{l} \text{Reversible process: } \Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} = 0 \\ \text{Irreversible process: } \Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} > 0 \end{array} \right\}$ [19.4] The second law of thermodynamics
- $S = k \ln W$ [19.5] Relating entropy to the number of microstates
- $\Delta S^\circ = \sum nS^\circ(\text{products}) - \sum mS^\circ(\text{reactants})$ [19.8] Calculating the standard entropy change from standard molar entropies
- $\Delta S_{\text{surr}} = \frac{-\Delta H_{\text{sys}}}{T}$ [19.9] The entropy change of the surroundings for a process at constant temperature and pressure
- $\Delta G = \Delta H - T\Delta S$ [19.11] Calculating the Gibbs free-energy change from enthalpy and entropy changes at constant temperature
- $\Delta G^\circ = \sum n\Delta G_f^\circ(\text{products}) - \sum m\Delta G_f^\circ(\text{reactants})$ [19.14] Calculating the standard free-energy change from standard free energies of formation
- $\left. \begin{array}{l} \text{Reversible process: } \Delta G = \Delta H_{\text{sys}} - T\Delta S_{\text{sys}} = 0 \\ \text{Irreversible process: } \Delta G = \Delta H_{\text{sys}} - T\Delta S_{\text{sys}} < 0 \end{array} \right\}$ [19.17] Relating the free-energy change to the reversibility of a process at constant temperature and pressure
- $\Delta G = -w_{\text{max}}$ [19.18] Relating the free-energy change to the maximum work a process can perform
- $\Delta G = \Delta G^\circ + RT \ln Q$ [19.19] Calculating free-energy change under nonstandard conditions
- $\Delta G^\circ = -RT \ln K$ [19.20] Relating the standard free-energy change and the equilibrium constant

EXERCISES

VISUALIZING CONCEPTS

- 19.1** Two different gases occupy the two bulbs shown here. Consider the process that occurs when the stopcock is opened, assuming the gases behave ideally. (a) Draw the final (equilibrium) state. (b) Predict the signs of ΔH and ΔS for the process. (c) Is the process that occurs when the stopcock is opened a reversible one? (d) How does the process affect the entropy of the surroundings? [Sections 19.1 and 19.2]

- 19.2** As shown here, one type of computer keyboard cleaner contains liquefied 1,1-difluoroethane ($\text{C}_2\text{H}_4\text{F}_2$), which is a gas at atmospheric pressure. When the nozzle is squeezed, the 1,1-difluoroethane vaporizes out of the nozzle at high pressure, blowing dust out of objects. (a) Based on your experience, is the vaporization a spontaneous process at room temperature? (b) Defining the 1,1-difluoroethane as the system, do you expect q_{sys} for the process to be positive or negative? Explain. (c) Predict whether ΔS is positive or negative for this process. (d) Given your answers to (a), (b), and (c), do you think the operation of this product depends more on heat flow or more on entropy change?

- 19.3 (a) What are the signs of ΔS and ΔH for the process depicted here? (b) How might temperature affect the sign of ΔG ? (c) If energy can flow in and out of the system to maintain a constant temperature during the process, what can you say about the entropy change of the surroundings as a result of this process? [Sections 19.2 and 19.5]

- 19.4 Predict the sign of ΔS accompanying this reaction. Explain your choice. [Section 19.3]

- 19.5 The accompanying diagram shows how entropy varies with temperature for a substance that is a gas at the highest temperature shown. (a) What processes correspond to the entropy increases along the vertical lines labeled 1 and 2? (b) Why is the entropy change for 2 larger than that for 1? [Section 19.3]

- 19.6 *Isomers* are molecules that have the same chemical formula but different arrangements of atoms, as shown here for two isomers of pentane, C_5H_{12} . (a) Do you expect a significant difference in the enthalpy of combustion of the two isomers? Explain. (b) Which isomer do you expect to have the higher standard molar entropy? Explain. [Section 19.4]

- 19.7 The accompanying diagram shows how ΔH (red line) and $T\Delta S$ (blue line) change with temperature for a hypothetical reaction. (a) What is the significance of the point at 300 K, where ΔH and $T\Delta S$ are equal? (b) In what temperature range is this reaction spontaneous? [Section 19.6]

- 19.8 The accompanying diagram shows how ΔG for a hypothetical reaction changes as temperature changes. (a) At what temperature is the system at equilibrium? (b) In what temperature range is the reaction spontaneous? (c) Is ΔH positive or negative? (d) Is ΔS positive or negative? [Sections 19.5 and 19.6]

- 19.9 Consider a reaction $A_2(g) + B_2(g) \rightleftharpoons 2 AB(g)$, with atoms of A shown in red in the diagram and atoms of B shown in blue. (a) If $K_c = 1$, which box represents the system at equilibrium? (b) What is the sign of ΔG for any process in which the contents of a reaction vessel move to equilibrium? (c) Rank the boxes in order of increasing magnitude of ΔG for the reaction. [Sections 19.5 and 19.7]

- 19.10 The accompanying diagram shows how the free energy, G , changes during a hypothetical reaction $A(g) + B(g) \rightarrow C(g)$. On the left are pure reactants, each at 1 atm, and on the right is the pure product, also at 1 atm. (a) What is the significance of the minimum in the plot? (b) What does the quantity x , shown on the right side of the diagram, represent? [Section 19.7]

SPONTANEOUS PROCESSES (section 19.1)

- 19.11** Which of the following processes are spontaneous and which are nonspontaneous: (a) the ripening of a banana, (b) dissolution of sugar in a cup of hot coffee, (c) the reaction of nitrogen atoms to form N_2 molecules at 25 °C and 1 atm, (d) lightning, (e) formation of CH_4 and O_2 molecules from CO_2 and H_2O at room temperature and 1 atm of pressure?
- 19.12** Which of the following processes are spontaneous: (a) the melting of ice cubes at -10 °C and 1 atm pressure; (b) separating a mixture of N_2 and O_2 into two separate samples, one that is pure N_2 and one that is pure O_2 ; (c) alignment of iron filings in a magnetic field; (d) the reaction of hydrogen gas with oxygen gas to form water vapor; (e) the dissolution of $HCl(g)$ in water to form concentrated hydrochloric acid?
- 19.13** (a) Give two examples of endothermic processes that are spontaneous. (b) Give an example of a process that is spontaneous at one temperature but nonspontaneous at a different temperature.
- 19.14** The crystalline hydrate $Cd(NO_3)_2 \cdot 4 H_2O(s)$ loses water when placed in a large, closed, dry vessel:
- $$Cd(NO_3)_2 \cdot 4 H_2O(s) \longrightarrow Cd(NO_3)_2(s) + 4 H_2O(g)$$
- This process is spontaneous and ΔH is positive. Is this process an exception to Bertholet's generalization that all spontaneous changes are exothermic? Explain.
- 19.15** Consider the vaporization of liquid water to steam at a pressure of 1 atm. (a) Is this process endothermic or exothermic? (b) In what temperature range is it a spontaneous process? (c) In what temperature range is it a nonspontaneous process? (d) At what temperature are the two phases in equilibrium?
- 19.16** The normal freezing point of *n*-octane (C_8H_{18}) is -57 °C. (a) Is the freezing of *n*-octane an endothermic or exothermic process? (b) In what temperature range is the freezing of *n*-octane a spontaneous process? (c) In what temperature range is it a nonspontaneous process? (d) Is there any temperature at which liquid *n*-octane and solid *n*-octane are in equilibrium? Explain.
- 19.17** (a) What is special about a *reversible* process? (b) Suppose a reversible process is reversed, restoring the system to its original

state. What can be said about the surroundings after the process is reversed? (c) Under what circumstances will the vaporization of water to steam be a reversible process? (d) Are any of the processes that occur in the world around us reversible in nature? Explain.

- 19.18** (a) What is meant by calling a process *irreversible*? (b) After a particular irreversible process, the system is restored to its original state. What can be said about the condition of the surroundings after the system is restored to its original state? (c) Under what conditions will the condensation of a liquid be an irreversible process?
- 19.19** Consider a process in which an ideal gas changes from state 1 to state 2 in such a way that its temperature changes from 300 K to 200 K. (a) Describe how this change might be carried out while keeping the volume of the gas constant. (b) Describe how it might be carried out while keeping the pressure of the gas constant. (c) Does the change in ΔE depend on the particular pathway taken to carry out this change of state? Explain.
- 19.20** A system goes from state 1 to state 2 and back to state 1. (a) What is the relationship between the value of ΔE for going from state 1 to state 2 to that for going from state 2 back to state 1? (b) Without further information, can you conclude anything about the amount of heat transferred to the system as it goes from state 1 to state 2 as compared to that upon going from state 2 back to state 1? (c) Suppose the changes in state are reversible processes. Can you conclude anything about the work done by the system upon going from state 1 to state 2 as compared to that upon going from state 2 back to state 1?
- 19.21** Consider a system consisting of an ice cube. (a) Under what conditions can the ice cube melt reversibly? (b) If the ice cube melts reversibly, is ΔE zero for the process? Explain.
- 19.22** Consider what happens when a sample of the explosive TNT (Section 8.8: "Chemistry Put to Work: Explosives and Alfred Nobel") is detonated under atmospheric pressure. (a) Is the detonation a spontaneous process? (b) What is the sign of q for this process? (c) Can you determine whether w is positive, negative, or zero for the process? Explain. (d) Can you determine the sign of ΔE for the process? Explain.

ENTROPY AND THE SECOND LAW OF THERMODYNAMICS (section 19.2)

- 19.23** (a) How can we calculate ΔS for an isothermal process? (b) Does ΔS for a process depend on the path taken from the initial state to the final state of the system? Explain.
- 19.24** Suppose we vaporize a mole of liquid water at 25 °C and another mole of water at 100 °C. (a) Assuming that the enthalpy of vaporization of water does not change much between 25 °C and 100 °C, which process involves the larger change in entropy? (b) Does the entropy change in either process depend on whether we carry out the process reversibly or not? Explain.
- 19.25** The normal boiling point of $Br_2(l)$ is 58.8 °C, and its molar enthalpy of vaporization is $\Delta H_{vap} = 29.6$ kJ/mol. (a) When $Br_2(l)$ boils at its normal boiling point, does its entropy increase or decrease? (b) Calculate the value of ΔS when 1.00 mol of $Br_2(l)$ is vaporized at 58.8 °C.
- 19.26** The element gallium (Ga) freezes at 29.8 °C, and its molar enthalpy of fusion is $\Delta H_{fus} = 5.59$ kJ/mol. (a) When molten

gallium solidifies to $Ga(s)$ at its normal melting point, is ΔS positive or negative? (b) Calculate the value of ΔS when 60.0 g of $Ga(l)$ solidifies at 29.8 °C.

- 19.27** (a) Express the second law of thermodynamics in words. (b) If the entropy of the system increases during a reversible process, what can you say about the entropy change of the surroundings? (c) In a certain spontaneous process the system undergoes an entropy change, $\Delta S = 42$ J/K. What can you conclude about ΔS_{surr} ?
- 19.28** (a) Express the second law of thermodynamics as a mathematical equation. (b) In a particular spontaneous process the entropy of the system decreases. What can you conclude about the sign and magnitude of ΔS_{surr} ? (c) During a certain reversible process, the surroundings undergo an entropy change, $\Delta S_{surr} = -78$ J/K. What is the entropy change of the system for this process?

19.29 (a) What sign for ΔS do you expect when the volume of 0.200 mol of an ideal gas at 27 °C is increased isothermally from an initial volume of 10.0 L? (b) If the final volume is 18.5 L, calculate the entropy change for the process. (c) Do you need to specify the temperature to calculate the entropy change? Explain.

19.30 (a) What sign for ΔS do you expect when the pressure on 0.600 mol of an ideal gas at 350 K is increased isothermally from an initial pressure of 0.750 atm? (b) If the final pressure on the gas is 1.20 atm, calculate the entropy change for the process. (c) Do you need to specify the temperature to calculate the entropy change? Explain.

THE MOLECULAR INTERPRETATION OF ENTROPY (section 19.3)

19.31 For the isothermal expansion of a gas into a vacuum, $\Delta E = 0$, $q = 0$, and $w = 0$. (a) Is this a spontaneous process? (b) Explain why no work is done by the system during this process. (c) In thermodynamics, what is the “driving force” for the expansion of the gas?

19.32 (a) What is the difference between a *state* and a *microstate* of a system? (b) As a system goes from state A to state B, its entropy decreases. What can you say about the number of microstates corresponding to each state? (c) In a particular spontaneous process, the number of microstates available to the system decreases. What can you conclude about the sign of ΔS_{surr} ?

19.33 How would each of the following changes affect the number of microstates available to a system: (a) increase in temperature, (b) decrease in volume, (c) change of state from liquid to gas?

19.34 (a) Using the heat of vaporization in Appendix B, calculate the entropy change for the vaporization of water at 25 °C and at 100 °C. (b) From your knowledge of microstates and the structure of liquid water, explain the difference in these two values.

19.35 (a) What do you expect for the sign of ΔS in a chemical reaction in which two moles of gaseous reactants are converted to three moles of gaseous products? (b) For which of the processes in Exercise 19.11 does the entropy of the system increase?

19.36 (a) In a chemical reaction two gases combine to form a solid. What do you expect for the sign of ΔS ? (b) How does the entropy of the system change in the processes described in Exercise 19.12?

19.37 How does the entropy of the system change when (a) a solid melts, (b) a gas liquefies, (c) a solid sublimates?

19.38 How does the entropy of the system change when (a) the temperature of the system increases, (b) the volume of a gas increases, (c) equal volumes of ethanol and water are mixed to form a solution?

19.39 (a) State the third law of thermodynamics. (b) Distinguish between translational motion, vibrational motion, and

rotational motion of a molecule. (c) Illustrate these three kinds of motion with sketches for the HCl molecule.

19.40 (a) If you are told that the entropy of a certain system is zero, what do you know about the system and the temperature? (b) The energy of a gas is increased by heating it. Using CO_2 as an example, illustrate the different ways in which additional energy can be distributed among the molecules of the gas. (c) $\text{CO}_2(\text{g})$ and $\text{Ar}(\text{g})$ have nearly the same molar mass. At a given temperature, will they have the same number of microstates? Explain.

19.41 For each of the following pairs, choose the substance with the higher entropy per mole at a given temperature: (a) $\text{Ar}(\text{l})$ or $\text{Ar}(\text{g})$, (b) $\text{He}(\text{g})$ at 3 atm pressure or $\text{He}(\text{g})$ at 1.5 atm pressure, (c) 1 mol of $\text{Ne}(\text{g})$ in 15.0 L or 1 mol of $\text{Ne}(\text{g})$ in 1.50 L, (d) $\text{CO}_2(\text{g})$ or $\text{CO}_2(\text{s})$.

19.42 For each of the following pairs, indicate which substance possesses the larger standard entropy: (a) 1 mol of $\text{P}_4(\text{g})$ at 300 °C, 0.01 atm, or 1 mol of $\text{As}_4(\text{g})$ at 300 °C, 0.01 atm; (b) 1 mol of $\text{H}_2\text{O}(\text{g})$ at 100 °C, 1 atm, or 1 mol of $\text{H}_2\text{O}(\text{l})$ at 100 °C, 1 atm; (c) 0.5 mol of $\text{N}_2(\text{g})$ at 298 K, 20-L volume, or 0.5 mol $\text{CH}_4(\text{g})$ at 298 K, 20-L volume; (d) 100 g $\text{Na}_2\text{SO}_4(\text{s})$ at 30 °C or 100 g $\text{Na}_2\text{SO}_4(\text{aq})$ at 30 °C.

19.43 Predict the sign of the entropy change of the system for each of the following reactions:

19.44 Predict the sign of ΔS_{sys} for each of the following processes: (a) Molten gold solidifies. (b) Gaseous Cl_2 dissociates in the stratosphere to form gaseous Cl atoms. (c) Gaseous CO reacts with gaseous H_2 to form liquid methanol, CH_3OH . (d) Calcium phosphate precipitates upon mixing $\text{Ca}(\text{NO}_3)_2(\text{aq})$ and $(\text{NH}_4)_3\text{PO}_4(\text{aq})$.

ENTROPY CHANGES IN CHEMICAL REACTIONS (section 19.4)

19.45 (a) Using Figure 19.13 as a model, sketch how the entropy of water changes as it is heated from -50 °C to 110 °C at sea level. Show the temperatures at which there are vertical increases in entropy. (b) Which process has the larger entropy change: melting ice or boiling water? Explain.

19.46 Propanol ($\text{C}_3\text{H}_7\text{OH}$) melts at -126.5 °C and boils at 97.4 °C. Draw a qualitative sketch of how the entropy changes as propanol vapor at 150 °C and 1 atm is cooled to solid propanol at -150 °C and 1 atm.

19.47 In each of the following pairs, which compound would you expect to have the higher standard molar entropy: (a) $\text{C}_2\text{H}_2(\text{g})$ or $\text{C}_2\text{H}_6(\text{g})$, (b) $\text{CO}_2(\text{g})$ or $\text{CO}(\text{g})$? Explain.

19.48 Cyclopropane and propylene are isomers (see Exercise 19.6) that both have the formula C_3H_6 . Based on the molecular structures shown, which of these isomers would you expect to have the higher standard molar entropy at 25 °C?

- 19.49** Use Appendix C to compare the standard entropies at 25 °C for the following pairs of substances: (a) Sc(s) and Sc(g), (b) NH₃(g) and NH₃(aq), (c) 1 mol P₄(g) and 2 mol P₂(g), (d) C(graphite) and C(diamond). In each case explain the difference in the entropy values.
- 19.50** Using Appendix C, compare the standard entropies at 25 °C for the following pairs of substances: (a) CuO(s) and Cu₂O(s), (b) 1 mol N₂O₄(g) and 2 mol NO₂(g), (c) SiO₂(s) and CO₂(g), (d) CO(g) and CO₂(g). For each pair, explain the difference in the entropy values.
- [19.51]** The standard entropies at 298 K for certain of the group 4A elements are as follows: C(s, diamond) = 2.43 J/mol-K, Si(s) = 18.81 J/mol-K, Ge(s) = 31.09 J/mol-K, and Sn(s) = 51.818 J/mol-K. All but Sn have the diamond structure. How do you account for the trend in the S° values?
- [19.52]** Three of the forms of elemental carbon are graphite, diamond, and buckminsterfullerene. The entropies at 298 K for graphite and diamond are listed in Appendix C. (a) Account

for the difference in the S° values of graphite and diamond in light of their structures (Figure 12.30). (b) What would you expect for the S° value of buckminsterfullerene (Figure 12.47) relative to the values for graphite and diamond? Explain.

- 19.53** Using S° values from Appendix C, calculate ΔS° values for the following reactions. In each case account for the sign of ΔS°.
- (a) C₂H₄(g) + H₂(g) → C₂H₆(g)
 (b) N₂O₄(g) → 2 NO₂(g)
 (c) Be(OH)₂(s) → BeO(s) + H₂O(g)
 (d) 2 CH₃OH(g) + 3 O₂(g) → 2 CO₂(g) + 4 H₂O(g)
- 19.54** Calculate ΔS° values for the following reactions by using tabulated S° values from Appendix C. In each case explain the sign of ΔS°.
- (a) HNO₃(g) + NH₃(g) → NH₄NO₃(s)
 (b) 2 Fe₂O₃(s) → 4 Fe(s) + 3 O₂(g)
 (c) CaCO₃(s, calcite) + 2HCl(g) → CaCl₂(s) + CO₂(g) + H₂O(l)
 (d) 3 C₂H₆(g) → C₆H₆(l) + 6 H₂(g)

GIBBS FREE ENERGY (sections 19.5 and 19.6)

- 19.55** (a) For a process that occurs at constant temperature, express the change in Gibbs free energy in terms of changes in the enthalpy and entropy of the system. (b) For a certain process that occurs at constant *T* and *P*, the value of Δ*G* is positive. What can you conclude? (c) What is the relationship between Δ*G* for a process and the rate at which it occurs?
- 19.56** (a) What is the meaning of the standard free-energy change, Δ*G*°, as compared with Δ*G*? (b) For any process that occurs at constant temperature and pressure, what is the significance of Δ*G* = 0? (c) For a certain process, Δ*G* is large and negative. Does this mean that the process necessarily occurs rapidly?
- 19.57** For a certain chemical reaction, Δ*H*° = -35.4 kJ and Δ*S*° = -85.5 J/K. (a) Is the reaction exothermic or endothermic? (b) Does the reaction lead to an increase or decrease in the randomness or disorder of the system? (c) Calculate Δ*G*° for the reaction at 298 K. (d) Is the reaction spontaneous at 298 K under standard conditions?
- 19.58** A certain reaction has Δ*H*° = +23.7 kJ and Δ*S*° = +52.4 J/K. (a) Is the reaction exothermic or endothermic? (b) Does the reaction lead to an increase or decrease in the randomness or disorder of the system? (c) Calculate Δ*G*° for the reaction at 298 K. (d) Is the reaction spontaneous at 298 K under standard conditions?
- 19.59** Using data in Appendix C, calculate Δ*H*°, Δ*S*°, and Δ*G*° at 298 K for each of the following reactions. In each case show that Δ*G*° = Δ*H*° - *T*Δ*S*°.
- (a) H₂(g) + F₂(g) → 2 HF(g)
 (b) C(s, graphite) + 2 Cl₂(g) → CCl₄(g)
 (c) 2 PCl₃(g) + O₂(g) → 2 POCl₃(g)
 (d) 2 CH₃OH(g) + H₂(g) → C₂H₆(g) + 2 H₂O(g)
- 19.60** Use data in Appendix C to calculate Δ*H*°, Δ*S*°, and Δ*G*° at 25 °C for each of the following reactions. In each case show that Δ*G*° = Δ*H*° - *T*Δ*S*°.
- (a) 2 Cr(s) + 3 O₂(g) → 2 CrO₃(s)
 (b) BaCO₃(s) → BaO(s) + CO₂(g)
 (c) 2 P(s) + 10 HF(g) → 2 PF₅(g) + 5 H₂(g)
 (d) K(s) + O₂(g) → KO₂(s)
- for the difference in the S° values of graphite and diamond in light of their structures (Figure 12.30). (b) What would you expect for the S° value of buckminsterfullerene (Figure 12.47) relative to the values for graphite and diamond? Explain.
- 19.61** Using data from Appendix C, calculate Δ*G*° for the following reactions. Indicate whether each reaction is spontaneous at 298 K under standard conditions.
- (a) 2 SO₂(g) + O₂(g) → 2 SO₃(g)
 (b) NO₂(g) + N₂O(g) → 3 NO(g)
 (c) 6 Cl₂(g) + 2 Fe₂O₃(s) → 4 FeCl₃(s) + 3 O₂(g)
 (d) SO₂(g) + 2 H₂(g) → S(s) + 2 H₂O(g)
- 19.62** Using data from Appendix C, calculate the change in Gibbs free energy for each of the following reactions. In each case indicate whether the reaction is spontaneous at 298 K under standard conditions.
- (a) 2 Ag(s) + Cl₂(g) → 2 AgCl(s)
 (b) P₄O₆(s) + 12 H₂(g) → 4 PH₃(g) + 6 H₂O(g)
 (c) CH₄(g) + 4 F₂(g) → CF₄(g) + 4 HF(g)
 (d) 2 H₂O₂(l) → 2 H₂O(l) + O₂(g)
- 19.63** Octane (C₈H₁₈) is a liquid hydrocarbon at room temperature that is the primary constituent of gasoline. (a) Write a balanced equation for the combustion of C₈H₁₈(l) to form CO₂(g) and H₂O(l). (b) Without using thermochemical data, predict whether Δ*G*° for this reaction is more negative or less negative than Δ*H*°.
- 19.64** Sulfur dioxide reacts with strontium oxide as follows:
- $$\text{SO}_2(\text{g}) + \text{SrO}(\text{s}) \longrightarrow \text{SrSO}_3(\text{s})$$
- (a) Without using thermochemical data, predict whether Δ*G*° for this reaction is more negative or less negative than Δ*H*°. (b) If you had only standard enthalpy data for this reaction, how would you go about making a rough estimate of the value of Δ*G*° at 298 K, using data from Appendix C on other substances?
- 19.65** Classify each of the following reactions as one of the four possible types summarized in Table 19.3:
- (a) N₂(g) + 3 F₂(g) → 2 NF₃(g)
 Δ*H*° = -249 kJ; Δ*S*° = -278 J/K
 (b) N₂(g) + 3 Cl₂(g) → 2 NCl₃(g)
 Δ*H*° = 460 kJ; Δ*S*° = -275 J/K
 (c) N₂F₄(g) → 2 NF₂(g)
 Δ*H*° = 85 kJ; Δ*S*° = 198 J/K

19.66 From the values given for ΔH° and ΔS° , calculate ΔG° for each of the following reactions at 298 K. If the reaction is not spontaneous under standard conditions at 298 K, at what temperature (if any) would the reaction become spontaneous?

19.67 A particular constant-pressure reaction is spontaneous at 390 K. The enthalpy change for the reaction is +23.7 kJ. What can you conclude about the sign and magnitude of ΔS for the reaction?

19.68 A certain constant-pressure reaction is nonspontaneous at 45 °C. The entropy change for the reaction is 72 J/K. What can you conclude about the sign and magnitude of ΔH ?

19.69 For a particular reaction, $\Delta H = -32 \text{ kJ}$ and $\Delta S = -98 \text{ J/K}$. Assume that ΔH and ΔS do not vary with temperature. (a) At what temperature will the reaction have $\Delta G = 0$? (b) If T is increased from that in part (a), will the reaction be spontaneous or nonspontaneous?

19.70 Reactions in which a substance decomposes by losing CO are called *decarbonylation* reactions. The decarbonylation of acetic acid proceeds as follows:

By using data from Appendix C, calculate the minimum temperature at which this process will be spontaneous under standard conditions. Assume that ΔH° and ΔS° do not vary with temperature.

19.71 Consider the following reaction between oxides of nitrogen:

(a) Use data in Appendix C to predict how ΔG° for the reaction varies with increasing temperature. (b) Calculate ΔG° at 800 K, assuming that ΔH° and ΔS° do not change with temperature. Under standard conditions is the reaction spontaneous at 800 K? (c) Calculate ΔG° at 1000 K. Is the reaction spontaneous under standard conditions at this temperature?

19.72 Methanol (CH_3OH) can be made by the controlled oxidation of methane:

(a) Use data in Appendix C to calculate ΔH° and ΔS° for this reaction. (b) How is ΔG° for the reaction expected to vary with increasing temperature? (c) Calculate ΔG° at 298 K. Under standard conditions, is the reaction spontaneous at this temperature? (d) Is there a temperature at which the reaction would be at equilibrium under standard conditions and that is low enough so that the compounds involved are likely to be stable?

19.73 (a) Use data in Appendix C to estimate the boiling point of benzene, $\text{C}_6\text{H}_6(l)$. (b) Use a reference source, such as the *CRC Handbook of Chemistry and Physics*, to find the experimental boiling point of benzene. How do you explain any deviation between your answer in part (a) and the experimental value?

19.74 (a) Using data in Appendix C, estimate the temperature at which the free-energy change for the transformation from $\text{I}_2(s)$ to $\text{I}_2(g)$ is zero. What assumptions must you make in arriving at this estimate? (b) Use a reference source, such as Web Elements (www.webelements.com), to find the experimental melting and boiling points of I_2 . (c) Which of the values in part (b) is closer to the value you obtained in part (a)? Can you explain why this is so?

19.75 Acetylene gas, $\text{C}_2\text{H}_2(g)$, is used in welding. (a) Write a balanced equation for the combustion of acetylene gas to $\text{CO}_2(g)$ and $\text{H}_2\text{O}(l)$. (b) How much heat is produced in burning 1 mol of C_2H_2 under standard conditions if both reactants and products are brought to 298 K? (c) What is the maximum amount of useful work that can be accomplished under standard conditions by this reaction?

19.76 The fuel in high-efficiency natural gas vehicles consists primarily of methane (CH_4). (a) How much heat is produced in burning 1 mol of $\text{CH}_4(g)$ under standard conditions if reactants and products are brought to 298 K and $\text{H}_2\text{O}(l)$ is formed? (b) What is the maximum amount of useful work that can be accomplished under standard conditions by this system?

FREE ENERGY AND EQUILIBRIUM (section 19.7)

19.77 Explain qualitatively how ΔG changes for each of the following reactions as the partial pressure of O_2 is increased:

19.78 Indicate whether ΔG increases, decreases, or does not change when the partial pressure of H_2 is increased in each of the following reactions:

19.79 Consider the reaction $2\text{NO}_2(g) \longrightarrow \text{N}_2\text{O}_4(g)$. (a) Using data from Appendix C, calculate ΔG° at 298 K. (b) Calculate ΔG at 298 K if the partial pressures of NO_2 and N_2O_4 are 0.40 atm and 1.60 atm, respectively.

19.80 Consider the reaction $3\text{CH}_4(g) \longrightarrow \text{C}_3\text{H}_8(g) + 2\text{H}_2(g)$. (a) Using data from Appendix C, calculate ΔG° at 298 K. (b) Calculate ΔG at 298 K if the reaction mixture consists of 40.0 atm of CH_4 , 0.0100 atm of $\text{C}_3\text{H}_8(g)$, and 0.0180 atm of H_2 .

19.81 Use data from Appendix C to calculate the equilibrium constant, K , at 298 K for each of the following reactions:

19.82 Using data from Appendix C, write the equilibrium-constant expression and calculate the value of the equilibrium constant for these reactions at 298 K:

19.83 Consider the decomposition of barium carbonate:

Using data from Appendix C, calculate the equilibrium pressure of CO_2 at (a) 298 K and (b) 1100 K.

19.84 Consider the reaction

Using data in Appendix C, calculate the equilibrium pressure of CO_2 in the system at (a) 400 °C and (b) 180 °C.

19.85 The value of K_a for nitrous acid (HNO_2) at 25°C is given in Appendix D. (a) Write the chemical equation for the equilibrium that corresponds to K_a . (b) By using the value of K_a , calculate ΔG° for the dissociation of nitrous acid in aqueous solution. (c) What is the value of ΔG at equilibrium? (d) What is the value of ΔG when $[\text{H}^+] = 5.0 \times 10^{-2} \text{ M}$, $[\text{NO}_2^-] = 6.0 \times 10^{-4} \text{ M}$, and $[\text{HNO}_2] = 0.20 \text{ M}$?

ADDITIONAL EXERCISES

19.87 (a) Which of the thermodynamic quantities T , E , q , w , and S are state functions? (b) Which depend on the path taken from one state to another? (c) How many *reversible* paths are there between two states of a system? (d) For a reversible isothermal process, write an expression for ΔE in terms of q and w and an expression for ΔS in terms of q and T .

19.88 Indicate whether each of the following statements is true or false. If it is false, correct it. (a) The feasibility of manufacturing NH_3 from N_2 and H_2 depends entirely on the value of ΔH for the process $\text{N}_2(\text{g}) + 3 \text{H}_2(\text{g}) \longrightarrow 2 \text{NH}_3(\text{g})$. (b) The reaction of $\text{Na}(\text{s})$ with $\text{Cl}_2(\text{g})$ to form $\text{NaCl}(\text{s})$ is a spontaneous process. (c) A spontaneous process can in principle be conducted reversibly. (d) Spontaneous processes in general require that work be done to force them to proceed. (e) Spontaneous processes are those that are exothermic and that lead to a higher degree of order in the system.

19.89 For each of the following processes, indicate whether the signs of ΔS and ΔH are expected to be positive, negative, or about zero. (a) A solid sublimates. (b) The temperature of a sample of $\text{Co}(\text{s})$ is lowered from 60°C to 25°C . (c) Ethyl alcohol evaporates from a beaker. (d) A diatomic molecule dissociates into atoms. (e) A piece of charcoal is combusted to form $\text{CO}_2(\text{g})$ and $\text{H}_2\text{O}(\text{g})$.

19.90 The reaction $2 \text{Mg}(\text{s}) + \text{O}_2(\text{g}) \longrightarrow 2 \text{MgO}(\text{s})$ is highly spontaneous and has a negative value for ΔS° . The second law of thermodynamics states that in any spontaneous process there is always an increase in the entropy of the universe. Is there an inconsistency between this reaction and the second law?

[19.91] Suppose four gas molecules are placed in the left flask in Figure 19.6(a). Initially, the right flask is evacuated and the stopcock is closed. (a) After the stopcock is opened, how many different arrangements of the molecules are possible? (b) How many of the arrangements from part (a) have all the molecules in the left flask? (c) How does the answer to part (b) explain the spontaneous expansion of the gas?

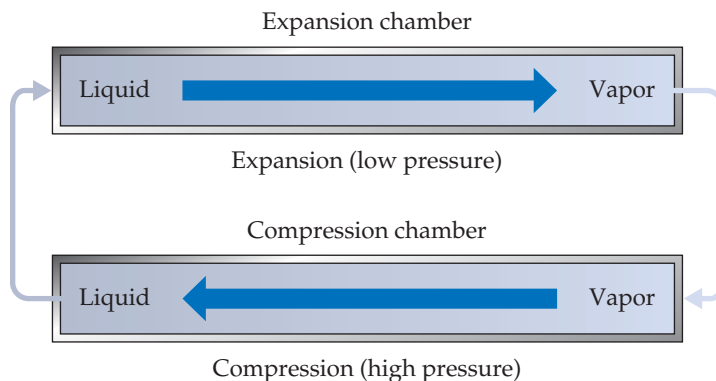

[19.92] Consider a system that consists of two standard playing dice, with the state of the system defined by the sum of the values shown on the top faces. (a) The two arrangements of top faces shown here can be viewed as two possible microstates of the system. Explain. (b) To which state does each microstate correspond? (c) How many possible states are there for the system? (d) Which state or states have the highest entropy? Explain. (e) Which state or states have the lowest entropy? Explain.

19.86 The K_b for methylamine (CH_3NH_2) at 25°C is given in Appendix D. (a) Write the chemical equation for the equilibrium that corresponds to K_b . (b) By using the value of K_b , calculate ΔG° for the equilibrium in part (a). (c) What is the value of ΔG at equilibrium? (d) What is the value of ΔG when $[\text{H}^+] = 6.7 \times 10^{-9} \text{ M}$, $[\text{CH}_3\text{NH}_3^+] = 2.4 \times 10^{-3} \text{ M}$, and $[\text{CH}_3\text{NH}_2] = 0.098 \text{ M}$?

19.93 Ammonium nitrate dissolves spontaneously and endothermally in water at room temperature. What can you deduce about the sign of ΔS for this solution process?

[19.94] A standard air conditioner involves a *refrigerant* that is typically now a fluorinated hydrocarbon, such as CH_2F_2 . An air-conditioner refrigerant has the property that it readily vaporizes at atmospheric pressure and is easily compressed to its liquid phase under increased pressure. The operation of an air conditioner can be thought of as a closed system made up of the refrigerant going through the two stages shown here (the air circulation is not shown in this diagram).

During *expansion*, the liquid refrigerant is released into an expansion chamber at low pressure, where it vaporizes. The vapor then undergoes *compression* at high pressure back to its liquid phase in a compression chamber. (a) What is the sign of q for the expansion? (b) What is the sign of q for the compression? (c) In a central air-conditioning system, one chamber is inside the home and the other is outside. Which chamber is where, and why? (d) Imagine that a sample of liquid refrigerant undergoes expansion followed by compression, so that it is back to its original state. Would you expect that to be a reversible process? (e) Suppose that a house and its exterior are both initially at 31°C . Some time after the air conditioner is turned on, the house is cooled to 24°C . Is this process spontaneous or nonspontaneous?

[19.95] *Trouton's rule* states that for many liquids at their normal boiling points, the standard molar entropy of vaporization is about $88 \text{ J/mol}\cdot\text{K}$. (a) Estimate the normal boiling point of bromine, Br_2 , by determining $\Delta H_{\text{vap}}^\circ$ for Br_2 using data from Appendix C. Assume that $\Delta H_{\text{vap}}^\circ$ remains constant with temperature and that Trouton's rule holds. (b) Look up the normal boiling point of Br_2 in a chemistry handbook or at the WebElements Web site (www.webelements.com).

[19.96] For the majority of the compounds listed in Appendix C, the value of ΔG_f° is more positive (or less negative) than the value of ΔH_f° . (a) Explain this observation, using $\text{NH}_3(\text{g})$, $\text{CCl}_4(\text{l})$, and $\text{KNO}_3(\text{s})$ as examples. (b) An exception to this observation is $\text{CO}(\text{g})$. Explain the trend in the ΔH_f° and ΔG_f° values for this molecule.

19.97 Consider the following three reactions:

(a) For each of the reactions, use data in Appendix C to calculate ΔH° , ΔG° , and ΔS° at 25 °C. (b) Which of these reactions are spontaneous under standard conditions at 25 °C? (c) For each of the reactions, predict the manner in which the change in free energy varies with an increase in temperature.

19.98 Using the data in Appendix C and given the pressures listed, calculate ΔG° for each of the following reactions:

19.99 (a) For each of the following reactions, predict the sign of ΔH° and ΔS° and discuss briefly how these factors determine the magnitude of K . (b) Based on your general chemical knowledge, predict which of these reactions will have $K > 0$. (c) In each case indicate whether K should increase or decrease with increasing temperature.

19.100 Acetic acid can be manufactured by combining methanol with carbon monoxide, an example of a *carbonylation* reaction:

(a) Calculate the equilibrium constant for the reaction at 25 °C. (b) Industrially, this reaction is run at temperatures above 25 °C. Will an increase in temperature produce an increase or decrease in the mole fraction of acetic acid at equilibrium? Why are elevated temperatures used? (c) At what temperature will this reaction have an equilibrium constant equal to 1? (You may assume that ΔH° and ΔS° are temperature independent, and you may ignore any phase changes that might occur.)

19.101 The oxidation of glucose ($\text{C}_6\text{H}_{12}\text{O}_6$) in body tissue produces CO_2 and H_2O . In contrast, anaerobic decomposition, which occurs during fermentation, produces ethanol ($\text{C}_2\text{H}_5\text{OH}$) and CO_2 . (a) Using data given in Appendix C, compare the equilibrium constants for the following reactions:

(b) Compare the maximum work that can be obtained from these processes under standard conditions.

[19.102] The conversion of natural gas, which is mostly methane, into products that contain two or more carbon atoms, such as ethane (C_2H_6), is a very important industrial chemical process. In principle, methane can be converted into ethane and hydrogen:

In practice, this reaction is carried out in the presence of oxygen:

(a) Using the data in Appendix C, calculate K for these reactions at 25 °C and 500 °C. (b) Is the difference in ΔG° for the two reactions due primarily to the enthalpy term (ΔH) or the

entropy term ($-T\Delta S$)? (c) Explain how the preceding reactions are an example of driving a nonspontaneous reaction, as discussed in the “Chemistry and Life” box in Section 19.7. (d) The reaction of CH_4 and O_2 to form C_2H_6 and H_2O must be carried out carefully to avoid a competing reaction. What is the most likely competing reaction?

[19.103] Cells use the hydrolysis of adenosine triphosphate (ATP) as a source of energy (Figure 19.19). The conversion of ATP to ADP has a standard free-energy change of -30.5 kJ/mol . If all the free energy from the metabolism of glucose,

goes into the conversion of ADP to ATP, how many moles of ATP can be produced for each mole of glucose?

[19.104] The potassium-ion concentration in blood plasma is about $5.0 \times 10^{-3} \text{ M}$, whereas the concentration in muscle-cell fluid is much greater (0.15 M). The plasma and intracellular fluid are separated by the cell membrane, which we assume is permeable only to K^+ . (a) What is ΔG for the transfer of 1 mol of K^+ from blood plasma to the cellular fluid at body temperature 37 °C? (b) What is the minimum amount of work that must be used to transfer this K^+ ?

[19.105] The relationship between the temperature of a reaction, its standard enthalpy change, and the equilibrium constant at that temperature can be expressed as the following linear equation:

$$\ln K = \frac{-\Delta H^\circ}{RT} + \text{constant}$$

(a) Explain how this equation can be used to determine ΔH° experimentally from the equilibrium constants at several different temperatures. (b) Derive the preceding equation using relationships given in this chapter. To what is the constant equal?

[19.106] One way to derive Equation 19.3 depends on the observation that at constant T the number of ways, W , of arranging m ideal-gas particles in a volume V is proportional to the volume raised to the m power:

$$W \propto V^m$$

Use this relationship and Boltzmann’s relationship between entropy and number of arrangements (Equation 19.5) to derive the equation for the entropy change for the isothermal expansion or compression of n moles of an ideal gas.

[19.107] About 86% of the world’s electrical energy is produced by using steam turbines, a form of heat engine. In his analysis of an ideal heat engine, Sadi Carnot concluded that the maximum possible efficiency is defined by the total work that could be done by the engine, divided by the quantity of heat available to do the work (for example, from hot steam produced by combustion of a fuel such as coal or methane). This efficiency is given by the ratio $(T_{\text{high}} - T_{\text{low}})/T_{\text{high}}$, where T_{high} is the temperature of the heat going into the engine and T_{low} is that of the heat leaving the engine. (a) What is the maximum possible efficiency of a heat engine operating between an input temperature of 700 K and an exit temperature of 288 K? (b) Why is it important that electrical power plants be located near bodies of relatively cool water? (c) Under what conditions could a heat engine operate at or near 100% efficiency? (d) It is often said that if the energy of combustion of a fuel such as methane were captured in an electrical fuel cell instead of by burning the fuel in a heat engine, a greater fraction of the energy could be put to useful work. Make a qualitative drawing like that in Figure 5.10 that illustrates the fact that in principle the fuel cell route will produce more useful work than the heat engine route from combustion of methane.

INTEGRATIVE EXERCISES

19.108 Most liquids follow Trouton's rule, which states that the molar entropy of vaporization lies in the range of 88 ± 5 J/mol-K. The normal boiling points and enthalpies of vaporization of several organic liquids are as follows:

Substance	Normal Boiling Point (°C)	ΔH_{vap} (kJ/mol)
Acetone, (CH ₃) ₂ CO	56.1	29.1
Dimethyl ether, (CH ₃) ₂ O	-24.8	21.5
Ethanol, C ₂ H ₅ OH	78.4	38.6
Octane, C ₈ H ₁₈	125.6	34.4
Pyridine, C ₅ H ₅ N	115.3	35.1

(a) Calculate ΔS_{vap} for each of the liquids. Do all the liquids obey Trouton's rule? (b) With reference to intermolecular forces (Section 11.2), can you explain any exceptions to the rule? (c) Would you expect water to obey Trouton's rule? By using data in Appendix B, check the accuracy of your conclusion. (d) Chlorobenzene (C₆H₅Cl) boils at 131.8 °C. Use Trouton's rule to estimate ΔH_{vap} for this substance.

19.109 In chemical kinetics the *entropy of activation* is the entropy change for the process in which the reactants reach the activated complex. The entropy of activation for bimolecular processes is usually negative. Explain this observation with reference to Figure 14.17.

19.110 The following processes were all discussed in Chapter 18, "Chemistry of the Environment." Estimate whether the entropy of the system increases or decreases during each process: (a) photodissociation of O₂(g), (b) formation of ozone from oxygen molecules and oxygen atoms, (c) diffusion of CFCs into the stratosphere, (d) desalination of water by reverse osmosis.

19.111 Carbon disulfide (CS₂) is a toxic, highly flammable substance. The following thermodynamic data are available for CS₂(l) and CS₂(g) at 298 K:

	ΔH_f° (kJ/mol)	ΔG_f° (kJ/mol)
CS ₂ (l)	89.7	65.3
CS ₂ (g)	117.4	67.2

(a) Draw the Lewis structure of the molecule. What do you predict for the bond order of the C—S bonds? (b) Use the VSEPR method to predict the structure of the CS₂ molecule. (c) Liquid CS₂ burns in O₂ with a blue flame, forming CO₂(g) and SO₂(g). Write a balanced equation for this reaction. (d) Using the data in the preceding table and in Appendix C, calculate ΔH° and ΔG° for the reaction in part (c). Is the reaction exothermic? Is it spontaneous at 298 K? (e) Use the data in the table to calculate ΔS° at 298 K for the vaporization of CS₂(l). Is the sign of ΔS° as you would expect for a vaporization? (f) Using data in the table and your answer to part (e), estimate the boiling point of CS₂(l). Do you predict that the substance will be a liquid or a gas at 298 K and 1 atm?

[19.112] The following data compare the standard enthalpies and free energies of formation of some crystalline ionic substances and aqueous solutions of the substances:

Substance	ΔH_f° (kJ/mol)	ΔG_f° (kJ/mol)
AgNO ₃ (s)	-124.4	-33.4
AgNO ₃ (aq)	-101.7	-34.2
MgSO ₄ (s)	-1283.7	-1169.6
MgSO ₄ (aq)	-1374.8	-1198.4

(a) Write the formation reaction for AgNO₃(s). Based on this reaction, do you expect the entropy of the system to increase or decrease upon the formation of AgNO₃(s)? (b) Use ΔH_f° and ΔG_f° of AgNO₃(s) to determine the entropy change upon formation of the substance. Is your answer consistent with your reasoning in part (a)? (c) Is dissolving AgNO₃ in water an exothermic or endothermic process? What about dissolving MgSO₄ in water? (d) For both AgNO₃ and MgSO₄, use the data to calculate the entropy change when the solid is dissolved in water. (e) Discuss the results from part (d) with reference to material presented in this chapter and in the "A Closer Look" box on page 540.

[19.113] Consider the following equilibrium:

Thermodynamic data on these gases are given in Appendix C. You may assume that ΔH° and ΔS° do not vary with temperature. (a) At what temperature will an equilibrium mixture contain equal amounts of the two gases? (b) At what temperature will an equilibrium mixture of 1 atm total pressure contain twice as much NO₂ as N₂O₄? (c) At what temperature will an equilibrium mixture of 10 atm total pressure contain twice as much NO₂ as N₂O₄? (d) Rationalize the results from parts (b) and (c) by using Le Châtelier's principle. [Section 15.7]

[19.114] The reaction

is the basis of a suggested method for removal of SO₂ from power-plant stack gases. The standard free energy of each substance is given in Appendix C. (a) What is the equilibrium constant for the reaction at 298 K? (b) In principle, is this reaction a feasible method of removing SO₂? (c) If $P_{\text{SO}_2} = P_{\text{H}_2\text{S}}$ and the vapor pressure of water is 25 torr, calculate the equilibrium SO₂ pressure in the system at 298 K. (d) Would you expect the process to be more or less effective at higher temperatures?

19.115 When most elastomeric polymers (e.g., a rubber band) are stretched, the molecules become more ordered, as illustrated here:

Suppose you stretch a rubber band. (a) Do you expect the entropy of the system to increase or decrease? (b) If the rubber band were stretched isothermally, would heat need to be absorbed or emitted to maintain constant temperature? (c) Try this experiment: Stretch a rubber band and wait a moment. Then place the stretched rubber band on your upper lip, and let it return suddenly to its unstretched state (remember to keep holding on). What do you observe? Are your observations consistent with your answer to part (b)?

WHAT'S AHEAD

20.1 OXIDATION STATES AND OXIDATION-REDUCTION REACTIONS

We review oxidation states and *oxidation-reduction (redox) reactions*.

20.2 BALANCING REDOX EQUATIONS

We learn how to balance redox equations using the method of *half-reactions*.

20.3 VOLTAIC CELLS

We consider *voltaic cells*, which produce electricity from spontaneous redox reactions. Solid electrodes serve as the

surfaces at which oxidation and reduction take place. The electrode where oxidation occurs is the *anode*, and the electrode where reduction occurs is the *cathode*.

20.4 CELL POTENTIALS UNDER STANDARD CONDITIONS

We see that an important characteristic of a voltaic cell is its *cell potential*, which is the difference in the electrical potentials at the two electrodes and is measured in units of volts. Half-cell potentials are tabulated for reduction half-reactions under standard conditions (*standard reduction potentials*).

20.5 FREE ENERGY AND REDOX REACTIONS

We relate the Gibbs free energy, ΔG° , to cell potential.

20

A VARIETY OF BATTERIES of different sizes, composition, and voltages.

20.6 CELL POTENTIALS UNDER NONSTANDARD CONDITIONS

We calculate cell potentials under nonstandard conditions by using standard cell potentials and the Nernst equation.

20.7 BATTERIES AND FUEL CELLS

We describe batteries and fuel cells, which are commercially important energy sources that use electrochemical reactions.

20.8 CORROSION

We discuss *corrosion*, a spontaneous electrochemical process involving metals.

20.9 ELECTROLYSIS

Finally, we focus on nonspontaneous redox reactions, examining *electrolytic cells*, which use electricity to perform chemical reactions.

ELECTRO-CHEMISTRY

WE ARE SURROUNDED BY AN amazing array of portable electronic gadgets, including cell phones, portable music players, laptop computers, and gaming devices. In the absence of batteries, however, our electronic gadgetry would be nothing more than extra weight. Thus, a variety of batteries of different sizes,

compositions, and voltages have been developed, some of which are shown in the chapter-opening photograph. Considerable research is in progress to develop new batteries with more power, faster recharging ability, lighter weight, or cheaper price. At the heart of such development are the oxidation-reduction reactions that power batteries.

As we discussed in Chapter 4, *oxidation* is the loss of electrons in a chemical reaction, and *reduction* is the gain of electrons. ∞ (Section 4.4) Thus, oxidation-reduction (redox) reactions occur when electrons are transferred from an atom that is oxidized to an atom that is reduced. Redox reactions are involved not only in the operation of batteries but also in a wide variety of important natural processes, including the rusting of iron, the browning of foods, and the respiration of animals. **Electrochemistry** is the study of the relationships between electricity and chemical reactions. It includes the study of both spontaneous and nonspontaneous processes.

20.1 OXIDATION STATES AND OXIDATION-REDUCTION REACTIONS

We determine whether a given chemical reaction is an oxidation-reduction reaction by keeping track of the *oxidation numbers* (*oxidation states*) of the elements involved in the reaction. ∞ (Section 4.4) This procedure identifies whether the oxidation state changes for any elements involved in the reaction. For example, consider the reaction that occurs spontaneously when zinc metal is added to a strong acid (\blacktriangledown FIGURE 20.1):

The chemical equation for this reaction can be written

From the oxidation numbers below the equation, we see that the oxidation number of Zn changes from 0 to +2 and that of H changes from +1 to 0. Thus, this is an oxidation-reduction reaction. Electrons are transferred from zinc atoms to hydrogen ions and, therefore, Zn is oxidized and H^+ is reduced.

GO FIGURE

Explain (a) the vigorous bubbling in the beaker on the right and (b) the formation of steam above that beaker.

\blacktriangleright FIGURE 20.1 Oxidation of zinc by hydrochloric acid.

In a reaction such as Equation 20.2, a clear transfer of electrons occurs. In some reactions, however, the oxidation numbers change, but we cannot say that any substance literally gains or loses electrons. For example, in the combustion of hydrogen gas,

hydrogen is oxidized from the 0 to the +1 oxidation state and oxygen is reduced from the 0 to the −2 oxidation state. Therefore, Equation 20.3 is an oxidation-reduction reaction. Water is not an ionic substance, however, and so there is not a complete transfer of electrons from hydrogen to oxygen as water is formed. Thus, keeping track of oxidation states is a convenient form of “bookkeeping,” but you should not generally equate the oxidation state of an atom with its actual charge in a chemical compound. ∞ (Section 8.5 “A Closer Look: Oxidation Numbers, Formal Charges, and Actual Partial Charges”)

GIVE IT SOME THOUGHT

What are the oxidation numbers of the elements in the nitrite ion, NO_2^- ?

In any redox reaction, both oxidation and reduction must occur. If one substance is oxidized, another must be reduced. The substance that makes it possible for another substance to be oxidized is called either the **oxidizing agent** or the **oxidant**. The oxidizing agent acquires electrons from the other substance and so is itself reduced. A **reducing agent**, or **reductant**, is a substance that gives up electrons, thereby causing another substance to be reduced. The reducing agent is therefore oxidized in the process. In Equation 20.2, $\text{H}^+(\text{aq})$, the species that is reduced, is the oxidizing agent and $\text{Zn}(\text{s})$, the species that is oxidized, is the reducing agent.

SAMPLE EXERCISE 20.1 Identifying Oxidizing and Reducing Agents

The nickel-cadmium (nicad) battery uses the following redox reaction to generate electricity:

Identify the substances that are oxidized and reduced, and indicate which is the oxidizing agent and which is the reducing agent.

SOLUTION

Analyze We are given a redox equation and asked to identify the substance oxidized and the substance reduced and to label the oxidizing agent and the reducing agent.

Plan First, we assign oxidation states, or numbers, to all the atoms and determine which elements change oxidation state. Second, we apply the definitions of oxidation and reduction.

The oxidation state of Cd increases from 0 to +2, and that of Ni decreases from +4 to +2. Thus, the Cd atom is oxidized (loses electrons) and is the reducing agent. The oxidation state of Ni decreases as NiO_2 is converted into $\text{Ni}(\text{OH})_2$. Thus, NiO_2 is reduced (gains electrons) and is the oxidizing agent.

Comment A common mnemonic for remembering oxidation and reduction is “LEO the lion says GER”: losing electrons is oxidation; gaining electrons is reduction.

PRACTICE EXERCISE

Identify the oxidizing and reducing agents in the reaction

Answer: $\text{Al}(\text{s})$ is the reducing agent; $\text{MnO}_4^-(\text{aq})$ is the oxidizing agent.

20.2 | BALANCING REDOX EQUATIONS

Whenever we balance a chemical equation, we must obey the law of conservation of mass: The amount of each element must be the same on both sides of the equation. (Atoms are neither created nor destroyed in any chemical reaction.) As we balance oxidation-reduction reactions, there is an additional requirement: The gains and losses of electrons must be balanced. If a substance loses a certain number of electrons during a reaction, another substance must gain that same number of electrons. (Electrons are neither created nor destroyed in any chemical reaction.)

In many simple chemical equations, such as Equation 20.2, balancing the electrons is handled “automatically” in the sense that we can balance the equation without explicitly considering the transfer of electrons. Many redox equations are more complex than Equation 20.2, however, and cannot be balanced easily without taking into account the number of electrons lost and gained. In this section we examine the *method of half-reactions*, a systematic procedure for balancing redox equations.

Half-Reactions

Although oxidation and reduction must take place simultaneously, it is often convenient to consider them as separate processes. For example, the oxidation of Sn^{2+} by Fe^{3+} ,

can be considered as consisting of two processes: oxidation of Sn^{2+} and reduction of Fe^{3+} :

Notice that electrons are shown as products in the oxidation process and as reactants in the reduction process.

Equations that show either oxidation or reduction alone, such as Equations 20.4 and 20.5, are called **half-reactions**. In the overall redox reaction, the number of electrons lost in the oxidation half-reaction must equal the number of electrons gained in the reduction half-reaction. When this condition is met and each half-reaction is balanced, the electrons on the two sides cancel when the two half-reactions are added to give the balanced oxidation-reduction equation.

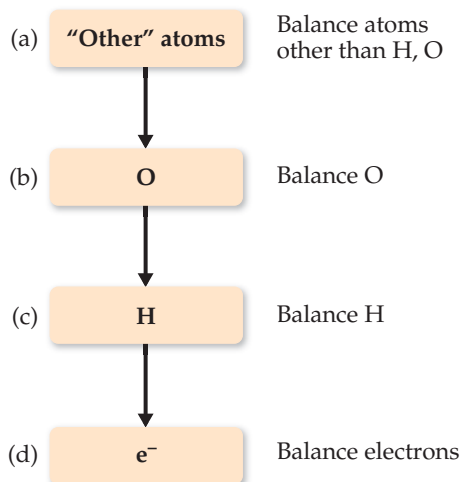

Balancing Equations by the Method of Half-Reactions

In using the half-reaction method, we usually begin with a “skeleton” ionic equation showing only the substances undergoing oxidation and reduction. In such cases, we usually do not need to assign oxidation numbers unless we are unsure whether the reaction involves oxidation-reduction. We will find that H^+ (for acidic solutions), OH^- (for basic solutions), and H_2O are often involved as reactants or products in redox reactions. Unless H^+ , OH^- , or H_2O is being oxidized or reduced, these species do not appear in the skeleton equation. Their presence, however, can be deduced as we balance the equation.

For balancing a redox reaction that occurs *in acidic aqueous* solution, the procedure is as follows:

1. Divide the equation into one oxidation half-reaction and one reduction half-reaction.
2. Balance each half-reaction.
 - (a) First, balance elements other than H and O.
 - (b) Next, balance O atoms by adding H_2O as needed.
 - (c) Then balance H atoms by adding H^+ as needed.
 - (d) Finally, balance charge by adding e^- as needed.

This specific sequence (a)–(d) is important, and it is summarized in the diagram in the margin. At this point, you can check whether the number of electrons in each half-reaction corresponds to the changes in oxidation state.

- Multiply half-reactions by integers as needed to make the number of electrons lost in the oxidation half-reaction equal the number of electrons gained in the reduction half-reaction.
- Add half-reactions and, if possible, simplify by canceling species appearing on both sides of the combined equation.
- Check to make sure that atoms and charges are balanced.

As an example, let's consider the reaction between permanganate ion (MnO_4^-) and oxalate ion ($\text{C}_2\text{O}_4^{2-}$) in acidic aqueous solution (▼ FIGURE 20.2). When MnO_4^- is added to an acidified solution of $\text{C}_2\text{O}_4^{2-}$, the deep purple color of the MnO_4^- ion fades, bubbles of CO_2 form, and the solution takes on the pale pink color of Mn^{2+} . We can therefore write the skeleton equation as

Experiments show that H^+ is consumed and H_2O is produced in the reaction. We will see that their involvement in the reaction is deduced in the course of balancing the equation.

To complete and balance Equation 20.6, we first write the two half-reactions (step 1). One half-reaction must have Mn on both sides of the arrow, and the other must have C on both sides of the arrow:

We next complete and balance each half-reaction. First, we balance all the atoms except H and O (step 2a). In the permanganate half-reaction, we have one manganese atom on each side of the equation and so need to do nothing. In the oxalate half-reaction, we add a coefficient 2 on the right to balance the two carbons on the left:

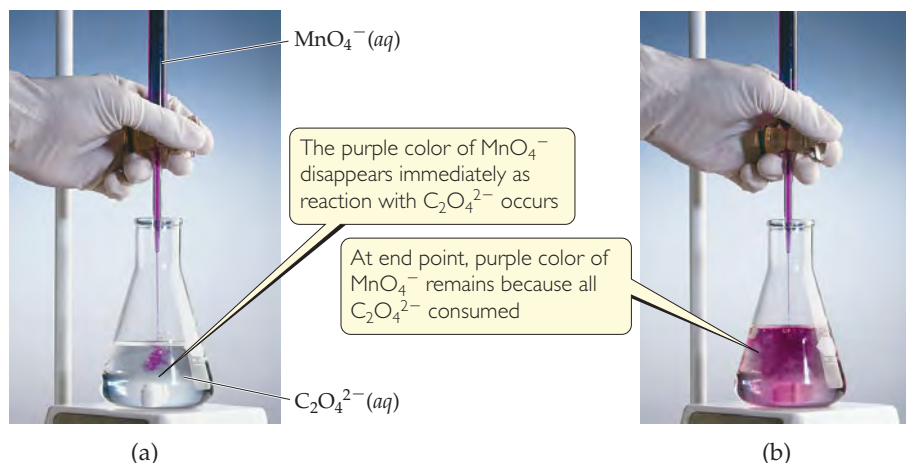

Next we balance O (step 2b). The permanganate half-reaction has four oxygens on the left and none on the right; therefore we need four H_2O molecules on the right to balance the oxygen atoms:

GO FIGURE

Which species is reduced in this reaction? Which species is the reducing agent?

◀ FIGURE 20.2 Titration of an acidic solution of $\text{Na}_2\text{C}_2\text{O}_4$ with $\text{KMnO}_4(aq)$.

The eight hydrogen atoms now in the products must be balanced by adding 8 H^+ to the reactants (step 2c):

There are now equal numbers of each type of atom on the two sides of the equation, but the charge still needs to be balanced. The charge of the reactants is $8(1+) + 1(1-) = 7+$, and that of the products is $1(2+) + 4(0) = 2+$. To balance the charge, we add five electrons to the reactant side (step 2d):

We can use oxidation states to check our result. In this half-reaction Mn goes from the +7 oxidation state in MnO_4^- to the +2 oxidation state of Mn^{2+} . Therefore, each Mn atom gains five electrons, in agreement with our balanced half-reaction.

In the oxalate half-reaction, we have C and O balanced (step 2a). We balance the charge (step 2d) by adding two electrons to the products:

We can check this result using oxidation states. Carbon goes from the +3 oxidation state in $\text{C}_2\text{O}_4^{2-}$ to the +4 oxidation state in CO_2 . Thus, each C atom loses one electron; therefore, the two C atoms in $\text{C}_2\text{O}_4^{2-}$ lose two electrons, in agreement with our balanced half-reaction.

Now we multiply each half-reaction by an appropriate integer so that the number of electrons gained in one half-reaction equals the number of electrons lost in the other (step 3). We multiply the MnO_4^- half-reaction by 2 and the $\text{C}_2\text{O}_4^{2-}$ half-reaction by 5:

The balanced equation is the sum of the balanced half-reactions (step 4). Note that the electrons on the reactant and product sides of the equation cancel each other.

We check the balanced equation by counting atoms and charges (step 5): There are 16 H, 2 Mn, 28 O, 10 C, and a net charge of $4+$ on each side of the equation, confirming that the equation is correctly balanced.

GIVE IT SOME THOUGHT

Do free electrons appear anywhere in the balanced equation for a redox reaction?

SAMPLE EXERCISE 20.2 Balancing Redox Equations in Acidic Solution

Complete and balance this equation by the method of half-reactions:

SOLUTION

Analyze We are given an incomplete, unbalanced (skeleton) equation for a redox reaction occurring in acidic solution and asked to complete and balance it.

Plan We use the half-reaction procedure we just learned.

Solve

Step 1: We divide the equation into two half-reactions:

$$\begin{array}{l} \text{Cr}_2\text{O}_7^{2-}(aq) \longrightarrow \text{Cr}^{3+}(aq) \\ \text{Cl}^-(aq) \longrightarrow \text{Cl}_2(g) \end{array}$$

Step 2: We balance each half-reaction. In the first half-reaction the presence of one $\text{Cr}_2\text{O}_7^{2-}$ among the reactants requires two Cr^{3+} among the products. The seven oxygen atoms in $\text{Cr}_2\text{O}_7^{2-}$ are balanced by adding seven H_2O to the products. The 14 hydrogen atoms in 7 H_2O are then balanced by adding 14 H^+ to the reactants:

We then balance the charge by adding electrons to the left side of the equation so that the total charge is the same on the two sides:

We can check this result by looking at the oxidation state changes. Each chromium atom goes from +6 to +3, gaining three electrons; therefore, the two Cr atoms in $\text{Cr}_2\text{O}_7^{2-}$ gain six electrons, in agreement with our half-reaction.

In the second half-reaction, two Cl^- are required to balance one Cl_2 :

We add two electrons to the right side to attain charge balance:

This result agrees with the oxidation state changes. Each chlorine atom goes from -1 to 0 , losing one electron; therefore, the two chlorine atoms lose two electrons.

Step 3: We equalize the number of electrons transferred in the two half-reactions. To do so, we multiply the Cl half-reaction by 3 so that the number of electrons gained in the Cr half-reaction (6) equals the number lost in the Cl half-reaction, allowing the electrons to cancel when the half-reactions are added:

Step 4: The equations are added to give the balanced equation:

Step 5: There are equal numbers of atoms of each kind on the two sides of the equation (14 H, 2 Cr, 7 O, 6 Cl). In addition, the charge is the same on the two sides ($6+$). Thus, the equation is balanced.

PRACTICE EXERCISE

Complete and balance the following equations using the method of half-reactions. Both reactions occur in acidic solution.

Balancing Equations for Reactions Occurring in Basic Solution

If a redox reaction occurs in basic solution, the equation must be balanced by using OH^- and H_2O rather than H^+ and H_2O . One approach is to first balance the half-reactions as if they occurred in acidic solution and then count the number of H^+ in each half-reaction and add the same number of OH^- to each side of the half-reaction. This way, the reaction is mass-balanced because you are adding the same thing to both sides. In essence, what you are doing is “neutralizing” the protons to form water ($\text{H}^+ + \text{OH}^- \longrightarrow \text{H}_2\text{O}$) on the side containing H^+ , and the other side ends up with the OH^- . The resulting water molecules can be canceled as needed.

SAMPLE EXERCISE 20.3 Balancing Redox Equations in Basic Solution

Complete and balance this equation for a redox reaction that takes place in basic solution:

**SOLUTION**

Analyze We are given an incomplete equation for a basic redox reaction and asked to balance it.

Plan We go through the first steps of our procedure as if the reaction were occurring in acidic solution. We then add the appropriate number of OH^- ions to each side of the equation, combining H^+ and OH^- to form H_2O . We complete the process by simplifying the equation.

Solve

Step 1: We write the incomplete, unbalanced half-reactions:

Step 2: We balance each half-reaction as if it took place in acidic solution:

Now we must take into account that the reaction occurs in basic solution, adding OH^- to both sides of both half-reactions to neutralize H^+ :

We “neutralize” H^+ and OH^- by forming H_2O when they are on the same side of either half-reaction:

Next, we cancel water molecules that appear as both reactants and products:

Both half-reactions are now balanced. You can check the atoms and the overall charge.

Step 3: We multiply the cyanide half-reaction by 3, which gives 6 electrons on the product side, and multiply the permanganate half-reaction by 2, which gives 6 electrons on the reactant side:

Step 4: We add the two half-reactions together and simplify by canceling species that appear as both reactants and products:

Step 5: Check that the atoms and charges are balanced.

There are 3 C, 3 N, 2 H, 9 O, 2 Mn, and a charge of 5^- on both sides of the equation.

Comment It is important to remember that this procedure doesn't imply that H^+ ions are involved in the chemical reaction. Recall that in aqueous solutions at 20°C , $K_w = [\text{H}^+][\text{OH}^-] = 1.0 \times 10^{-14}$. Thus, $[\text{H}^+]$ is very small in this basic solution.  (Section 16.3)

PRACTICE EXERCISE

Complete and balance the following equations for oxidation-reduction reactions that occur in basic solution:

GO FIGURE

Why does the intensity of the blue solution color lessen as the reaction proceeds?

▲ FIGURE 20.3 A spontaneous oxidation-reduction reaction involving zinc and copper.

20.3 VOLTAIC CELLS

The energy released in a spontaneous redox reaction can be used to perform electrical work. This task is accomplished through a **voltaic** (or **galvanic**) **cell**, a device in which the transfer of electrons takes place through an external pathway rather than directly between reactants present in the same reaction vessel.

One such spontaneous reaction occurs when a strip of zinc is placed in contact with a solution containing Cu^{2+} . As the reaction proceeds, the blue color of $\text{Cu}^{2+}(\text{aq})$ ions fades, and copper metal deposits on the zinc. At the same time, the zinc begins to dissolve. These transformations, shown in ▲ FIGURE 20.3, are summarized by the equation

► FIGURE 20.4 shows a voltaic cell that uses the redox reaction given in Equation 20.7. Although the setup in Figure 20.4 is more complex than that in Figure 20.3, the reaction is the same in both cases. The significant difference is that in the voltaic cell the Zn metal and $\text{Cu}^{2+}(\text{aq})$ are not in direct contact with each other. Instead, Zn metal is in contact with $\text{Zn}^{2+}(\text{aq})$ in one compartment, and Cu metal is in contact with $\text{Cu}^{2+}(\text{aq})$ in the other compartment. Consequently, Cu^{2+} reduction can occur only by the flow of electrons through an external circuit, namely, a wire connecting the Zn and Cu strips. Electrons flowing through a wire and ions moving in solution both constitute an *electrical current*. This flow of electrical charge can be used to accomplish electrical work.

GO FIGURE

Which metal, Cu or Zn, is oxidized in this voltaic cell?

▲ FIGURE 20.4 A Cu-Zn voltaic cell based on the reaction in Equation 20.7.

The two solid metals connected by the external circuit are called *electrodes*. By definition, the electrode at which oxidation occurs is the **anode** and the electrode at which reduction occurs is the **cathode**.* The electrodes can be made of materials that participate in the reaction, as in the present example. Over the course of the reaction, the Zn electrode gradually disappears and the copper electrode gains mass. More typically, the electrodes are made of a conducting material, such as platinum or graphite, that does not gain or lose mass during the reaction but serves as a surface at which electrons are transferred.

Each compartment of a voltaic cell is called a *half-cell*. One half-cell is the site of the oxidation half-reaction, and the other is the site of the reduction half-reaction. In our present example, Zn is oxidized and Cu^{2+} is reduced:

Electrons become available as zinc metal is oxidized at the anode. They flow through the external circuit to the cathode, where they are consumed as $\text{Cu}^{2+}(\text{aq})$ is reduced. Because Zn(s) is oxidized in the cell, the zinc electrode loses mass, and the concentration of the Zn^{2+} solution increases as the cell operates. At the same time, the Cu electrode gains mass, and the Cu^{2+} solution becomes less concentrated as Cu^{2+} is reduced to Cu(s).

For a voltaic cell to work, the solutions in the two half-cells must remain electrically neutral. As Zn is oxidized in the anode half-cell, Zn^{2+} ions enter the solution, upsetting the initial $\text{Zn}^{2+}/\text{SO}_4^{2-}$ charge balance. To keep the solution electrically neutral, there must be some means for Zn^{2+} cations to migrate out of the anode half-cell and for anions to migrate in. Similarly, the reduction of Cu^{2+} at the cathode removes these cations from the solution, leaving an excess of SO_4^{2-} anions in that half-cell. To maintain electrical neutrality, some of these anions must migrate out of the cathode half-cell, and positive ions must migrate in. In fact, no measurable electron flow occurs between electrodes unless a means is provided for ions to migrate through the solution from one half-cell to the other, thereby completing the circuit.

In Figure 20.4, a porous glass disc separating the two half-cells allows ions to migrate and maintain the electrical neutrality of the solutions. In ▼ FIGURE 20.5, a *salt bridge*

GO FIGURE

How is electrical balance maintained in the left beaker as Zn^{2+} ions are formed at the anode?

▲ FIGURE 20.5 A voltaic cell that uses a salt bridge to complete the electrical circuit.

*To help remember these definitions, note that *anode* and *oxidation* both begin with a vowel, and *cathode* and *reduction* both begin with a consonant.

serves this purpose. The salt bridge consists of a U-shaped tube containing an electrolyte solution, such as $\text{NaNO}_3(aq)$, whose ions will not react with other ions in the voltaic cell or with the electrodes. The electrolyte is often incorporated into a paste or gel so that the electrolyte solution does not pour out when the U-tube is inverted. As oxidation and reduction proceed at the electrodes, ions from the salt bridge migrate into the two half-cells—cations migrating to the cathode half-cell and anions migrating to the anode half-cell—to neutralize charge in the half-cell solutions. Whichever device is used to allow ions to migrate between half-cells, *anions always migrate toward the anode and cations toward the cathode*.

► **FIGURE 20.6** summarizes the various relationships in a voltaic cell. Notice in particular that *electrons flow from the anode through the external circuit to the cathode*. Because of this directional flow, the anode in a voltaic cell is labeled with a negative sign and the cathode is labeled with a positive sign. We can envision the electrons as being attracted to the positive cathode from the negative anode through the external circuit.

▲ **FIGURE 20.6** Summary of reactions occurring in a voltaic cell. The half-cells can be separated by either a porous glass disc (as in Figure 20.4) or by a salt bridge (as in Figure 20.5).

SAMPLE EXERCISE 20.4 Describing a Voltaic Cell

The oxidation-reduction reaction

is spontaneous. A solution containing $\text{K}_2\text{Cr}_2\text{O}_7$ and H_2SO_4 is poured into one beaker, and a solution of KI is poured into another. A salt bridge is used to join the beakers. A metallic conductor that will not react with either solution (such as platinum foil) is suspended in each solution, and the two conductors are connected with wires through a voltmeter or some other device to detect an electric current. The resultant voltaic cell generates an electric current. Indicate the reaction occurring at the anode, the reaction at the cathode, the direction of electron migration, the direction of ion migration, and the signs of the electrodes.

SOLUTION

Analyze We are given the equation for a spontaneous reaction that takes place in a voltaic cell and a description of how the cell is constructed. We are asked to write the half-reactions occurring at the anode and at the cathode, as well as the directions of electron and ion movements and the signs assigned to the electrodes.

Plan Our first step is to divide the chemical equation into half-reactions so that we can identify the oxidation and the reduction processes. We then use the definitions of anode and cathode and the other terminology summarized in Figure 20.6.

Solve In one half-reaction, $\text{Cr}_2\text{O}_7^{2-}(aq)$ is converted into $\text{Cr}^{3+}(aq)$. Starting with these ions and then completing and balancing the half-reaction, we have

In the other half-reaction, $\text{I}^-(aq)$ is converted to $\text{I}_2(s)$:

Now we can use the summary in Figure 20.6 to help us describe the voltaic cell. The first half-reaction is the reduction process (electrons on the reactant side of the equation). By definition, the reduction process occurs at the cathode. The second half-reaction is the oxidation process (electrons on the product side of the equation), which occurs at the anode.

The I^- ions are the source of electrons, and the $\text{Cr}_2\text{O}_7^{2-}$ ions accept the electrons. Hence, the electrons flow through the external circuit from the electrode immersed in the KI solution (the anode) to the electrode immersed in the $\text{K}_2\text{Cr}_2\text{O}_7\text{-H}_2\text{SO}_4$ solution (the cathode). The electrodes themselves do not react in any way; they merely provide a means of transferring electrons from or to the solutions. The cations move through the solutions toward the cathode, and the anions move toward the anode. The anode (from which the electrons move) is the negative electrode, and the cathode (toward which the electrons move) is the positive electrode.

PRACTICE EXERCISE

The two half-reactions in a voltaic cell are

(a) Indicate which reaction occurs at the anode and which at the cathode. (b) Which electrode is consumed in the cell reaction? (c) Which electrode is positive?

Answers: (a) The first reaction occurs at the anode and the second reaction at the cathode. (b) The anode (Zn) is consumed in the cell reaction. (c) The cathode is positive.

20.4 CELL POTENTIALS UNDER STANDARD CONDITIONS

Why do electrons transfer spontaneously from a Zn atom to a Cu^{2+} ion, either directly as in Figure 20.3 or through an external circuit as in Figure 20.4? In a simple sense, we can compare the electron flow to the flow of water in a waterfall (▼ FIGURE 20.7). Water flows spontaneously over a waterfall because of a difference in potential energy between the top of the falls and the bottom. ∞ (Section 5.1) In a similar fashion, electrons flow spontaneously through an external circuit from the anode of a voltaic cell to the cathode because of a difference in potential energy. The potential energy of electrons is higher in the anode than in the cathode. Thus, electrons flow spontaneously toward the electrode with the more positive electrical potential.

The difference in potential energy per electrical charge (the *potential difference*) between two electrodes is measured in volts. One volt (V) is the potential difference required to impart 1 joule (J) of energy to a charge of 1 coulomb (C):

$$1 \text{ V} = 1 \frac{\text{J}}{\text{C}}$$

Recall that one electron has a charge of $1.60 \times 10^{-19} \text{ C}$. ∞ (Section 2.2)

The potential difference between the two electrodes of a voltaic cell is called the **cell potential**, denoted E_{cell} . Because the potential difference provides the driving force that pushes electrons through the external circuit, we also call it the **electromotive force** (“causing electron motion”) **force**, or **emf**. Because E_{cell} is measured in volts, it is also commonly called the *voltage* of the cell.

The cell potential of any voltaic cell is positive. The magnitude of the cell potential depends on the reactions that occur at the cathode and anode, the concentrations of reactants and products, and the temperature, which we will assume to be 25°C unless otherwise noted. In this section we focus on cells that are operated at 25°C under *standard conditions*. Recall from Table 19.2 that standard conditions include 1 M concentrations for reactants and products in solution and 1 atm pressure for gaseous reactants and products. The cell potential under standard conditions is called either the **standard cell potential** or **standard emf** and is denoted E_{cell}° . For the Zn-Cu voltaic cell in Figure 20.5, for example, the standard cell potential at 25°C is $+1.10 \text{ V}$:

Recall that the superscript $^\circ$ indicates standard-state conditions. ∞ (Section 5.7)

► FIGURE 20.7 Water analogy for electron flow.

GIVE IT SOME THOUGHT

If a standard cell potential is $E_{\text{cell}}^{\circ} = +0.85 \text{ V}$ at 25°C , is the redox reaction of the cell spontaneous?

Standard Reduction Potentials

The standard cell potential of a voltaic cell, E_{cell}° , depends on the particular cathode and anode half-cells. We could, in principle, tabulate the standard cell potentials for all possible cathode/anode combinations. However, it is not necessary to undertake this arduous task. Rather, we can assign a standard potential to each half-cell and then use these half-cell potentials to determine E_{cell}° . The cell potential is the difference between two half-cell potentials. By convention, the potential associated with each electrode is chosen to be the potential for *reduction* at that electrode. Thus, standard half-cell potentials are tabulated for reduction reactions, which means they are **standard reduction potentials**, denoted E_{red}° . The standard cell potential, E_{cell}° , is the standard reduction potential of the cathode reaction, E_{red}° (cathode), *minus* the standard reduction potential of the anode reaction, E_{red}° (anode):

$$E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ} (\text{cathode}) - E_{\text{red}}^{\circ} (\text{anode}) \quad [20.8]$$

It is not possible to measure the standard reduction potential of a half-reaction directly. If we assign a standard reduction potential to a certain reference half-reaction, however, we can then determine the standard reduction potentials of other half-reactions relative to that reference value. The reference half-reaction is the reduction of $\text{H}^{+}(\text{aq})$ to $\text{H}_2(\text{g})$ under standard conditions, which is assigned a standard reduction potential of exactly 0 V:

An electrode designed to produce this half-reaction is called a **standard hydrogen electrode** (SHE). An SHE consists of a platinum wire connected to a piece of platinum foil covered with finely divided platinum that serves as an inert surface for the reaction (▼ FIGURE 20.8). The SHE allows the platinum to be in contact with both $1 \text{ M H}^{+}(\text{aq})$ and a stream of hydrogen gas at 1 atm. The SHE can operate as either the anode or cathode of a cell, depending on the nature of the other electrode.

► FIGURE 20.9 shows a voltaic cell using an SHE. The spontaneous reaction is the one shown in Figure 20.1, namely, oxidation of Zn and reduction of H^{+} :

◀ FIGURE 20.8 The standard hydrogen electrode (SHE) is used as a reference electrode.

GO FIGURE

Why does Na^+ migrate into the cathode half-cell as the cell reaction proceeds?

► **FIGURE 20.9** A voltaic cell using a standard hydrogen electrode (SHE). The anode half-cell is Zn metal in a $\text{Zn}(\text{NO}_3)_2(\text{aq})$ solution, and the cathode half-cell is the SHE in a $\text{HNO}_3(\text{aq})$ solution.

When the cell is operated under standard conditions, the cell potential is $+0.76\text{ V}$. By using the standard cell potential ($E_{\text{cell}}^\circ = 0.76\text{ V}$), the defined standard reduction potential of H^+ ($E_{\text{red}}^\circ = 0\text{ V}$) and Equation 20.8, we can determine the standard reduction potential for the Zn^{2+}/Zn half-reaction:

$$\begin{aligned} E_{\text{cell}}^\circ &= E_{\text{red}}^\circ(\text{cathode}) - E_{\text{red}}^\circ(\text{anode}) \\ +0.76\text{ V} &= 0\text{ V} - E_{\text{red}}^\circ(\text{anode}) \\ E_{\text{red}}^\circ(\text{anode}) &= -0.76\text{ V} \end{aligned}$$

Thus, a standard reduction potential of -0.76 V can be assigned to the reduction of Zn^{2+} to Zn:

We write the reaction as a reduction even though the Zn reaction in Figure 20.9 is an oxidation. *Whenever we assign an electrical potential to a half-reaction, we write the reaction as a reduction.* Half-reactions, however, are reversible, being able to operate as either reductions or oxidations. Consequently, half-reactions are sometimes written using two arrows (\rightleftharpoons) between reactants and products, as in equilibrium reactions.

The standard reduction potentials for other half-reactions can be determined in a fashion analogous to that used for the Zn^{2+}/Zn half-reaction. ► **TABLE 20.1** lists some standard reduction potentials; a more complete list is found in Appendix E. These standard reduction potentials, often called *half-cell potentials*, can be combined to calculate E_{cell}° values for a large variety of voltaic cells.

GIVE IT SOME THOUGHT

For the half-reaction $\text{Cl}_2(\text{g}) + 2\text{e}^- \longrightarrow 2\text{Cl}^-(\text{aq})$, what are the standard conditions for the reactant and product?

Because electrical potential measures potential energy per electrical charge, standard reduction potentials are intensive properties. ∞ (Section 1.3) In other words, if we increase the amount of substances in a redox reaction, we increase both the energy and the charges involved, but the ratio of energy (joules) to electrical charge (coulombs) remains constant ($\text{V} = \text{J}/\text{C}$). Thus, *changing the stoichiometric coefficient in a half-reaction does not affect the value of the standard reduction potential.* For example, E_{red}° for the reduction of 10 mol Zn^{2+} is the same as that for the reduction of 1 mol Zn^{2+} :

TABLE 20.1 • Standard Reduction Potentials in Water at 25 °C

E_{red}° (V)	Reduction Half-Reaction
+2.87	$\text{F}_2(\text{g}) + 2 \text{e}^{-} \longrightarrow 2 \text{F}^{-}(\text{aq})$
+1.51	$\text{MnO}_4^{-}(\text{aq}) + 8 \text{H}^{+}(\text{aq}) + 5 \text{e}^{-} \longrightarrow \text{Mn}^{2+}(\text{aq}) + 4 \text{H}_2\text{O}(\text{l})$
+1.36	$\text{Cl}_2(\text{g}) + 2 \text{e}^{-} \longrightarrow 2 \text{Cl}^{-}(\text{aq})$
+1.33	$\text{Cr}_2\text{O}_7^{2-}(\text{aq}) + 14 \text{H}^{+}(\text{aq}) + 6 \text{e}^{-} \longrightarrow 2 \text{Cr}^{3+}(\text{aq}) + 7 \text{H}_2\text{O}(\text{l})$
+1.23	$\text{O}_2(\text{g}) + 4 \text{H}^{+}(\text{aq}) + 4 \text{e}^{-} \longrightarrow 2 \text{H}_2\text{O}(\text{l})$

-2.71	$\text{Na}^{+}(\text{aq}) + \text{e}^{-} \longrightarrow \text{Na}(\text{s})$
-3.05	$\text{Li}^{+}(\text{aq}) + \text{e}^{-} \longrightarrow \text{Li}(\text{s})$

SAMPLE EXERCISE 20.5 Calculating E_{red}° from E_{cell}°

For the Zn-Cu²⁺ voltaic cell shown in Figure 20.5, we have

Given that the standard reduction potential of Zn²⁺ to Zn(s) is -0.76 V, calculate the E_{red}° for the reduction of Cu²⁺ to Cu:

**SOLUTION**

Analyze We are given E_{cell}° and E_{red}° for Zn²⁺ and asked to calculate E_{red}° for Cu²⁺.

Plan In the voltaic cell, Zn is oxidized and is therefore the anode. Thus, the given E_{red}° for Zn²⁺ is E_{red}° (anode). Because Cu²⁺ is reduced, it is in the cathode half-cell. Thus, the unknown reduction potential for Cu²⁺ is E_{red}° (cathode). Knowing E_{cell}° and E_{red}° (anode), we can use Equation 20.8 to solve for E_{red}° (cathode).

Solve

$$E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode})$$

$$1.10 \text{ V} = E_{\text{red}}^{\circ}(\text{cathode}) - (-0.76 \text{ V})$$

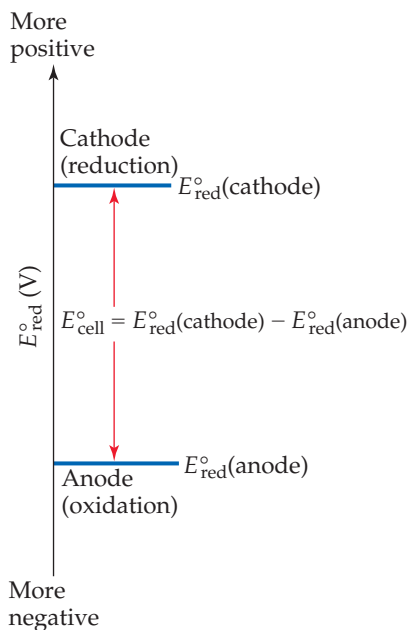

$$E_{\text{red}}^{\circ}(\text{cathode}) = 1.10 \text{ V} - 0.76 \text{ V} = 0.34 \text{ V}$$

Check This standard reduction potential agrees with the one listed in Table 20.1.

Comment: The standard reduction potential for Cu²⁺ can be represented as $E_{\text{Cu}^{2+}}^{\circ} = 0.34 \text{ V}$ and that for Zn²⁺ as $E_{\text{Zn}^{2+}}^{\circ} = -0.76 \text{ V}$. The subscript identifies the ion that is reduced in the reduction half-reaction.

GO FIGURE

Given E_{red}° values for the two electrodes in a standard voltaic cell, how do you determine which electrode is the cathode?

▲ FIGURE 20.10 Graphical representation of standard cell potential of a voltaic cell.

▲ FIGURE 20.11 Half-cell potentials and standard cell potential for the Zn-Cu voltaic cell.

PRACTICE EXERCISE

The standard cell potential is 1.46 V for a voltaic cell based on the following half-reactions:

Using Table 20.1, calculate E_{red}° for the reduction of In^{3+} to In^+ .

Answer: -0.40 V

SAMPLE EXERCISE 20.6 Calculating E_{cell}° from E_{red}°

Use Table 20.1 to calculate E_{cell}° for the voltaic cell described in Sample Exercise 20.4, which is based on the reaction

SOLUTION

Analyze We are given the equation for a redox reaction and asked to use data in Table 20.1 to calculate the standard cell potential for the associated voltaic cell.

Plan Our first step is to identify the half-reactions that occur at the cathode and anode, which we did in Sample Exercise 20.4. Then we use Table 20.1 and Equation 20.8 to calculate the standard cell potential.

Solve The half-reactions are

According to Table 20.1, the standard reduction potential for the reduction of $\text{Cr}_2\text{O}_7^{2-}$ to Cr^{3+} is +1.33 V and the standard reduction potential for the reduction of I_2 to I^- (the reverse of the oxidation half-reaction) is +0.54 V. We use these values in Equation 20.8:

$$E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode}) = 1.33\text{ V} - 0.54\text{ V} = 0.79\text{ V}$$

Although we must multiply the iodide half-reaction by 3 to obtain a balanced equation, we do *not* multiply the E_{red}° value by 3. As we have noted, the standard reduction potential is an intensive property and so is independent of the stoichiometric coefficients.

Check The cell potential, 0.79 V, is a positive number. As noted earlier, a voltaic cell must have a positive potential.

PRACTICE EXERCISE

Using data in Table 20.1, calculate the standard emf for a cell that employs the overall cell reaction $2\text{Al}(s) + 3\text{I}_2(s) \longrightarrow 2\text{Al}^{3+}(aq) + 6\text{I}^-(aq)$.

Answer: $0.54\text{ V} - (-1.66\text{ V}) = 2.20\text{ V}$

For each half-cell in a voltaic cell, the standard reduction potential provides a measure of the tendency for reduction to occur: *The more positive the value of E_{red}° , the greater the tendency for reduction under standard conditions.* In any voltaic cell operating under standard conditions, the E_{red}° value for the reaction at the cathode is more positive than the E_{red}° value for the reaction at the anode. Thus, electrons flow spontaneously through the external circuit from the electrode with the more negative value of E_{red}° to the electrode with the more positive value of E_{red}° .

The fact that the standard cell potential is the difference between the standard reduction potentials of cathode and anode is illustrated graphically in ◀ FIGURE 20.10. The more positive E_{red}° value identifies the cathode, and the difference between the two standard reduction potentials is the standard cell potential. ◀ FIGURE 20.11 shows E_{red}° values for the two half-reactions in the Zn-Cu voltaic cell of Figure 20.5.

SAMPLE EXERCISE 20.7 Determining Half-Reactions at Electrodes and Calculating Cell Potentials

A voltaic cell is based on the two standard half-reactions

Use data in Appendix E to determine (a) which half-reaction occurs at the cathode and which occurs at the anode and (b) the standard cell potential.

SOLUTION

Analyze We have to look up E_{red}° for two half-reactions. We then use these values first to determine the cathode and the anode and then to calculate the standard cell potential, E_{cell}° .

Plan The cathode will have the reduction with the more positive E_{red}° value, and the anode will have the less positive E_{red}° . To write the half-reaction at the anode, we reverse the half-reaction written for the reduction, so that the half-reaction is written as an oxidation.

Solve

(a) According to Appendix E, $E_{\text{red}}^{\circ}(\text{Cd}^{2+}/\text{Cd}) = -0.403 \text{ V}$ and $E_{\text{red}}^{\circ}(\text{Sn}^{2+}/\text{Sn}) = -0.136 \text{ V}$. The standard reduction potential for Sn^{2+} is more positive (less negative) than that for Cd^{2+} . Hence, the reduction of Sn^{2+} is the reaction that occurs at the cathode:

The anode reaction, therefore, is the loss of electrons by Cd:

(b) The cell potential is given by the difference in the standard reduction potentials at the cathode and anode (Equation 20.8):

$$E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode}) = (-0.136 \text{ V}) - (-0.403 \text{ V}) = 0.267 \text{ V}$$

Notice that it is unimportant that the E_{red}° values of both half-reactions are negative; the negative values merely indicate how these reductions compare to the reference reaction, the reduction of $\text{H}^{+}(\text{aq})$.

Check: The cell potential is positive, as it must be for a voltaic cell.

PRACTICE EXERCISE

A voltaic cell is based on a Co^{2+}/Co half-cell and an AgCl/Ag half-cell.

(a) What half-reaction occurs at the anode? (b) What is the standard cell potential?

Answers: (a) $\text{Co} \longrightarrow \text{Co}^{2+} + 2 \text{e}^{-}$; (b) $+0.499 \text{ V}$

Strengths of Oxidizing and Reducing Agents

Table 20.1 lists half-reactions in order of decreasing tendency to undergo reduction. For example, F_2 is located at the top of the table, having the most positive value for E_{red}° . Thus, F_2 is the most easily reduced species in Table 20.1 and therefore the strongest oxidizing agent listed.

Among the most frequently used oxidizing agents are the halogens, O_2 , and oxyanions such as MnO_4^{-} , $\text{Cr}_2\text{O}_7^{2-}$, and NO_3^{-} , whose central atoms have high positive oxidation states. As seen in Table 20.1, all these species have large positive values of E_{red}° and therefore easily undergo reduction.

The lower the tendency for a half-reaction to occur in one direction, the greater the tendency for it to occur in the opposite direction. Thus, *the half-reaction with the most negative reduction potential in Table 20.1 is the one most easily reversed and run as an oxidation*. Being at the bottom of Table 20.1, $\text{Li}^{+}(\text{aq})$ is the most difficult species in the list to reduce and is therefore the poorest oxidizing agent listed. Although $\text{Li}^{+}(\text{aq})$ has little tendency to gain electrons, the reverse reaction, oxidation of $\text{Li}(\text{s})$ to $\text{Li}^{+}(\text{aq})$, is highly favorable. Thus, Li is the strongest reducing agent among the substances listed in Table 20.1. (Note that, because Table 20.1 lists half-reactions as reductions, only the

substances on the reactant side of these equations can serve as oxidizing agents; only those on the product side can serve as reducing agents.)

Commonly used reducing agents include H_2 and the active metals, such as the alkali metals and the alkaline earth metals. Other metals whose cations have negative E_{red}° values—Zn and Fe, for example—are also used as reducing agents. Solutions of reducing agents are difficult to store for extended periods because of the ubiquitous presence of O_2 , a good oxidizing agent.

The information contained in Table 20.1 is summarized graphically in **FIGURE 20.12**. The reactants in half-reactions at the top of Table 20.1 are the most readily reduced species in the table and are therefore the strongest oxidizing agents. Thus, Figure 20.12 shows $\text{F}_2(\text{g})$ as the strongest oxidizing agent (the position at the top of the red arrow). The products in half-reactions at the top of Table 20.1 are the most difficult to oxidize and are therefore the weakest reducing agents in the table. The reactants in half-reactions at the bottom of Table 20.1 are the most difficult to reduce and so are the weakest oxidizing agents. The products in half-reactions at the bottom of Table 20.1 are the most readily oxidized species in the table and so are the strongest reducing agents.

This inverse relationship between oxidizing and reducing strength is similar to the inverse relationship between the strengths of conjugate acids and bases. [∞ \(Section 16.2 and Figure 16.3\)](#)

GO FIGURE

Why is a strong oxidizing agent easy to reduce?

► FIGURE 20.12 Relative strengths of oxidizing and reducing agents. The standard reduction potentials in Table 20.1 are related to the ability of substances to serve as oxidizing or reducing agents. Species on the left side of the half-reactions can act as oxidizing agents, and those on the right side can act as reducing agents.

SAMPLE EXERCISE 20.8 Determining Relative Strengths of Oxidizing Agents

Using Table 20.1, rank the following ions in order of increasing strength as oxidizing agents: $\text{NO}_3^-(aq)$, $\text{Ag}^+(aq)$, $\text{Cr}_2\text{O}_7^{2-}(aq)$.

SOLUTION

Analyze We are asked to rank the abilities of several ions to act as oxidizing agents.

Plan The more readily an ion is reduced (the more positive its E_{red}° value), the stronger it is as an oxidizing agent.

Solve From Table 20.1, we have

Because the standard reduction potential of $\text{Cr}_2\text{O}_7^{2-}$ is the most positive, $\text{Cr}_2\text{O}_7^{2-}$ is the strongest oxidizing agent of the three. The rank order is $\text{Ag}^+ < \text{NO}_3^- < \text{Cr}_2\text{O}_7^{2-}$.

PRACTICE EXERCISE

Using Table 20.1, rank the following species from the strongest to the weakest reducing agent: $\text{I}^-(aq)$, $\text{Fe}(s)$, $\text{Al}(s)$.

Answer: $\text{Al}(s) > \text{Fe}(s) > \text{I}^-(aq)$

20.5 FREE ENERGY AND REDOX REACTIONS

We have observed that voltaic cells use spontaneous redox reactions to produce a positive cell potential. We can use this fact together with half-cell potentials to decide whether a given redox reaction is spontaneous. In doing so, it is useful to make Equation 20.8 more general so that we can see how it pertains to general redox reactions, not just reactions in voltaic cells:

$$E^\circ = E_{\text{red}}^\circ (\text{reduction process}) - E_{\text{red}}^\circ (\text{oxidation process}) \quad [20.10]$$

In writing the equation this way, we have dropped the subscript “cell” to indicate that the calculated emf does not necessarily refer to a voltaic cell. Also, we have generalized the standard reduction potentials by using the general terms *reduction* and *oxidation* rather than the terms specific to voltaic cells, *cathode* and *anode*. We can now make a general statement about the spontaneity of a reaction and its associated emf, E : *A positive value of E indicates a spontaneous process; a negative value of E indicates a nonspontaneous process.* We use E to represent the emf under nonstandard conditions and E° to indicate the standard emf.

SAMPLE EXERCISE 20.9 Determining Spontaneity

Use Table 20.1 to determine whether the following reactions are spontaneous under standard conditions.

- (a) $\text{Cu}(s) + 2\text{H}^+(aq) \longrightarrow \text{Cu}^{2+}(aq) + \text{H}_2(g)$
 (b) $\text{Cl}_2(g) + 2\text{I}^-(aq) \longrightarrow 2\text{Cl}^-(aq) + \text{I}_2(s)$

SOLUTION

Analyze We are given two reactions and must determine whether each is spontaneous.

Plan To determine whether a redox reaction is spontaneous under standard conditions, we first need to write its reduction and oxidation half-reactions. We can then use the standard reduction potentials and

Equation 20.10 to calculate the standard emf, E° , for the reaction. If a reaction is spontaneous, its standard emf must be a positive number.

Solve

(a) For oxidation of Cu to Cu^{2+} and reduction of H^+ to H_2 , the half-reactions and standard reduction potentials are

Notice that for the oxidation, we use the standard reduction potential from Table 20.1 for the reduction of Cu^{2+} to Cu. We now calculate E° by using Equation 20.10:

$$\begin{aligned} E^\circ &= E_{\text{red}}^\circ (\text{reduction process}) - E_{\text{red}}^\circ (\text{oxidation process}) \\ &= (0 \text{ V}) - (0.34 \text{ V}) = -0.34 \text{ V} \end{aligned}$$

Because E° is negative, the reaction is not spontaneous in the direction written. Copper metal does not react with acids in this fashion. The reverse reaction, however, is spontaneous and has a positive E° value:

Thus, Cu^{2+} can be reduced by H_2 .

(b) We follow a procedure analogous to that in (a):

In this case

$$E^\circ = (1.36 \text{ V}) - (0.54 \text{ V}) = +0.82 \text{ V}$$

Because the value of E° is positive, this reaction is spontaneous and could be used to build a voltaic cell.

PRACTICE EXERCISE

Using the standard reduction potentials listed in Appendix E, determine which of the following reactions are spontaneous under standard conditions:

Answer: Reactions (b) and (c) are spontaneous.

We can use standard reduction potentials to understand the activity series of metals. [∞ \(Section 4.4\)](#) Recall that any metal in the activity series (Table 4.5) is oxidized by the ions of any metal below it. We can now recognize the origin of this rule based on standard reduction potentials. The activity series is based on the oxidation reactions of the metals, ordered from strongest reducing agent at the top to weakest reducing agent at the bottom. (Thus, the ordering is inverted relative to that in Table 20.1.) For example, nickel lies above silver in the activity series, making nickel the stronger reducing agent. Because a reducing agent is oxidized in any redox reaction, nickel is more easily oxidized than silver. In a mixture of nickel metal and silver cations, therefore, we expect a displacement reaction in which the silver ions are displaced in the solution by nickel ions:

In this reaction Ni is oxidized and Ag^+ is reduced. Therefore, the standard emf for the reaction is

$$\begin{aligned} E^\circ &= E_{\text{red}}^\circ (\text{Ag}^+/\text{Ag}) - E_{\text{red}}^\circ (\text{Ni}^{2+}/\text{Ni}) \\ &= (+0.80 \text{ V}) - (-0.28 \text{ V}) = +1.08 \text{ V} \end{aligned}$$

The positive value of E° indicates that the displacement of silver by nickel resulting from oxidation of Ni metal and reduction of Ag^+ is a spontaneous process. Remember that although we multiply the silver half-reaction by 2, the reduction potential is not multiplied.

GIVE IT SOME THOUGHT

Based on Table 4.5, which is the stronger reducing agent, $\text{Hg}(\text{l})$ or $\text{Pb}(\text{s})$?

Emf, Free Energy, and the Equilibrium Constant

The change in the Gibbs free energy, ΔG , is a measure of the spontaneity of a process that occurs at constant temperature and pressure. ∞ (Section 19.5) The emf, E , of a redox reaction also indicates whether the reaction is spontaneous. The relationship between emf and the free-energy change is

$$\Delta G = -nFE \quad [20.11]$$

In this equation, n is a positive number without units that represents the number of moles of electrons transferred according to the balanced equation for the reaction, and F is **Faraday's constant**, named after Michael Faraday (► FIGURE 20.13):

$$F = 96,485 \text{ C/mol} = 96,485 \text{ J/V}\cdot\text{mol}$$

Faraday's constant is the quantity of electrical charge on 1 mol of electrons.

The units of ΔG calculated with Equation 20.11 are J/mol. As in Equation 19.19, we use "per mole" to mean per mole of reaction as indicated by the coefficients in the balanced equation. ∞ (Section 19.7)

Because both n and F are positive numbers, a positive value of E in Equation 20.11 leads to a negative value of ΔG . Remember: *A positive value of E and a negative value of ΔG both indicate a spontaneous reaction.* When the reactants and products are all in their standard states, Equation 20.11 can be modified to relate ΔG° and E° :

$$\Delta G^\circ = -nFE^\circ \quad [20.12]$$

Because ΔG° is related to the equilibrium constant, K , for a reaction by the expression $\Delta G^\circ = -RT \ln K$ (Equation 19.20), we can relate E° to K by solving Equation 20.12 for E° and then substituting the Equation 19.20 expression for ΔG° :

$$E^\circ = \frac{\Delta G^\circ}{-nF} = \frac{-RT \ln K}{-nF} = \frac{RT}{nF} \ln K \quad [20.13]$$

▼ FIGURE 20.14 summarizes the relationships among E° , ΔG° , and K .

▲ FIGURE 20.13 **Michael Faraday.** Faraday (1791–1867) was born in England, a child of a poor blacksmith. At the age of 14 he was apprenticed to a bookbinder who gave him time to read and to attend lectures. In 1812 he became an assistant in Humphry Davy's laboratory at the Royal Institution. He succeeded Davy as the most famous and influential scientist in England, making an amazing number of important discoveries, including his formulation of the quantitative relationships between electrical current and the extent of chemical reaction in electrochemical cells.

GO FIGURE

What does the variable n represent in the ΔG° and E° equations?

▲ FIGURE 20.14 **Relationships of E° , ΔG° , and K .** Any one of these important parameters can be used to calculate the other two. The signs of E° and ΔG° determine the direction that the reaction proceeds under standard conditions. The magnitude of K determines the relative amounts of reactants and products in an equilibrium mixture.

SAMPLE EXERCISE 20.10 Using Standard Reduction Potentials to Calculate ΔG° and K

(a) Use the standard reduction potentials in Table 20.1 to calculate the standard free-energy change, ΔG° , and the equilibrium constant, K , at 298 K for the reaction

(b) Suppose the reaction in part (a) is written

What are the values of E° , ΔG° , and K when the reaction is written in this way?

SOLUTION

Analyze We are asked to determine ΔG° and K for a redox reaction, using standard reduction potentials.

Plan We use the data in Table 20.1 and Equation 20.10 to determine E° for the reaction and then use E° in Equation 20.12 to calculate ΔG° . We can then use Equation 19.20, $\Delta G^\circ = -RT \ln K$, to calculate K .

Alternatively, we can calculate K using Equation 20.13, $E^\circ = \frac{RT}{nF} \ln K$.

Solve

(a) We first calculate E° by breaking the equation into two half-reactions and obtaining E°_{red} values from Table 20.1 (or Appendix E):

Even though the second half-reaction has 4 Ag, we use the E°_{red} value directly from Table 20.1 because emf is an intensive property.

Using Equation 20.10, we have $E^\circ = (1.23 \text{ V}) - (0.80 \text{ V}) = 0.43 \text{ V}$

The half-reactions show the transfer of four electrons. Thus, for this reaction $n = 4$. We now use Equation 20.12 to calculate ΔG° :

$$\begin{aligned} \Delta G^\circ &= -nFE^\circ \\ &= -(4)(96,485 \text{ J/V}\cdot\text{mol})(+0.43 \text{ V}) \\ &= -1.7 \times 10^5 \text{ J/mol} = -170 \text{ kJ/mol} \end{aligned}$$

The positive value of E° leads to a negative value of ΔG° . The per mol part of the unit relates to the balanced equation, $4 \text{Ag}(\text{s}) + \text{O}_2(\text{g}) + 4 \text{H}^+(\text{aq}) \longrightarrow 4 \text{Ag}^+(\text{aq}) + 2 \text{H}_2\text{O}(\text{l})$. Thus, -170 kJ is associated with 4 mol Ag, 1 mol O_2 and 4 mol H^+ , and so forth, corresponding to the coefficients in the balanced equation.

Now we need to calculate the equilibrium constant, K , using $\Delta G^\circ = RT \ln K$. Because ΔG° is a large negative number, which means the reaction is thermodynamically very favorable, we expect K to be large.

$$\begin{aligned} \Delta G^\circ &= -RT \ln K \\ -1.7 \times 10^5 \text{ J/mol} &= -(8.314 \text{ J/K}\cdot\text{mol})(298 \text{ K}) \ln K \\ \ln K &= \frac{-1.7 \times 10^5 \text{ J/mol}}{-(8.314 \text{ J/K}\cdot\text{mol})(298 \text{ K})} \\ \ln K &= 69 \\ K &= 9 \times 10^{29} \end{aligned}$$

K is indeed very large! This means that we expect silver metal to oxidize in acidic aqueous environments, in air, to Ag^+ .

Notice that the emf calculated for the reaction was $E^\circ = 0.43 \text{ V}$, which is easy to measure. Directly measuring such a large equilibrium constant by measuring reactant and product concentrations at equilibrium, on the other hand, would be very difficult.

(b) The overall equation is the same as that in part (a), multiplied by $\frac{1}{2}$. The half-reactions are

The values of E°_{red} are the same as they were in part (a); they are not changed by multiplying the half-reactions by $\frac{1}{2}$. Thus, E° has the same value as in part (a):

$$E^\circ = +0.43 \text{ V}$$

Notice, though, that the value of n has changed to $n = 2$, which is one-half the value in part (a). Thus, ΔG° is half as large as in part (a):

$$\Delta G^\circ = -(2)(96,485 \text{ J/V}\cdot\text{mol})(+0.43 \text{ V}) = -83 \text{ kJ/mol}$$

The value of ΔG° is half that in part (a) because the coefficients in the chemical equation are half those in (a).

Now we can calculate K as before:

$$\begin{aligned} -8.3 \times 10^4 \text{ J/mol} &= -(8.314 \text{ J/K}\cdot\text{mol})(298 \text{ K}) \ln K \\ K &= 4 \times 10^{14} \end{aligned}$$

Comment E° is an *intensive* quantity, so multiplying a chemical equation by a certain factor will not affect the value of E° . Multiplying an equation will change the value of n , however, and hence the value

of ΔG° . The change in free energy, in units of J/mol of reaction as written, is an *extensive* quantity. The equilibrium constant is also an extensive quantity.

PRACTICE EXERCISE

For the reaction

(a) What is the value of n ? (b) Use the data in Appendix E to calculate ΔG° . (c) Calculate K at $T = 298 \text{ K}$.

Answers: (a) 6, (b) +87 kJ/mol, (c) $K = 6 \times 10^{-16}$

A CLOSER LOOK

ELECTRICAL WORK

For any spontaneous process, ΔG is a measure of the maximum useful work, w_{max} , that can be extracted from the process: $\Delta G = w_{\text{max}}$. ∞ (Section 19.5)

Because $\Delta G = -nFE$, the maximum useful electrical work obtainable from a voltaic cell is

$$w_{\text{max}} = -nFE_{\text{cell}} \quad [20.14]$$

Because cell emf, E_{cell} , is always positive for a voltaic cell, w_{max} is negative, indicating that work is done *by* a system *on* its surroundings, as we expect for a voltaic cell. ∞ (Section 5.2)

As Equation 20.14 shows, the more charge a voltaic cell moves through a circuit (that is, the larger nF is) and the larger the emf pushing the electrons through the circuit (that is, the larger E_{cell} is), the more work the cell can accomplish. In Sample Exercise 20.10, we calculated $\Delta G^\circ = -170 \text{ kJ/mol}$ for the reaction $4 \text{Ag}(\text{s}) + \text{O}_2(\text{g}) + 4 \text{H}^+(\text{aq}) \longrightarrow 4 \text{Ag}^+(\text{aq}) + 2 \text{H}_2\text{O}(\text{l})$. Thus, a voltaic cell utilizing this reaction could perform a maximum of 170 kJ of work in consuming 4 mol Ag, 1 mol O_2 , and 4 mol H^+ .

If a reaction is not spontaneous, ΔG is positive and E is negative. To force a nonspontaneous reaction to occur in an electrochemical cell, we need to apply an external potential, E_{ext} , that exceeds $|E_{\text{cell}}|$. For example, if a nonspontaneous process has $E = -0.9 \text{ V}$, then the external potential E_{ext} must be greater than $+0.9 \text{ V}$ in order for the process to occur. We will examine such nonspontaneous processes in Section 20.9.

Electrical work can be expressed in energy units of watts times time. The *watt* (W) is a unit of electrical power (that is, rate of energy expenditure):

$$1 \text{ W} = 1 \text{ J/s}$$

Thus, a watt-second is a joule. The unit employed by electric utilities is the kilowatt-hour (kWh), which equals $3.6 \times 10^6 \text{ J}$:

$$1 \text{ kWh} = (1000 \text{ W})(1 \text{ hr}) \left(\frac{3600 \text{ s}}{1 \text{ hr}} \right) \left(\frac{1 \text{ J/s}}{1 \text{ W}} \right) = 3.6 \times 10^6 \text{ J}$$

20.6 CELL POTENTIALS UNDER NONSTANDARD CONDITIONS

We have seen how to calculate the emf of a cell when the reactants and products are under standard conditions. As a voltaic cell is discharged, however, reactants are consumed and products are generated, so concentrations change. The emf progressively drops until $E = 0$, at which point we say the cell is “dead.” In this section we examine how the emf generated under nonstandard conditions can be calculated by using an equation first derived by Walther Nernst (1864–1941), a German chemist who established many of the theoretical foundations of electrochemistry.

The Nernst Equation

The effect of concentration on cell emf can be obtained from the effect of concentration on free-energy change. ∞ (Section 19.7) Recall that the free-energy change for any chemical reaction, ΔG , is related to the standard free-energy change for the reaction, ΔG° :

$$\Delta G = \Delta G^\circ + RT \ln Q \quad [20.15]$$

The quantity Q is the reaction quotient, which has the form of the equilibrium-constant expression except that the concentrations are those that exist in the reaction mixture at a given moment. ∞ (Section 15.6)

Substituting $\Delta G = -nFE$ (Equation 20.11) into Equation 20.15 gives

$$-nFE = -nFE^\circ + RT \ln Q$$

Solving this equation for E gives the **Nernst equation**:

$$E = E^\circ - \frac{RT}{nF} \ln Q \quad [20.16]$$

This equation is customarily expressed in terms of the base-10 logarithm:

$$E = E^\circ - \frac{2.303 RT}{nF} \log Q \quad [20.17]$$

At $T = 298 \text{ K}$ the quantity $2.303 RT/F$ equals 0.0592, with units of volts, and so the Nernst equation simplifies to

$$E = E^\circ - \frac{0.0592 \text{ V}}{n} \log Q \quad (T = 298 \text{ K}) \quad [20.18]$$

We can use this equation to find the emf E produced by a cell under nonstandard conditions or to determine the concentration of a reactant or product by measuring E for the cell. For example, consider the following reaction:

In this case $n = 2$ (two electrons are transferred from Zn to Cu^{2+}), and the standard emf is +1.10 V (Section 20.4). Thus, at 298 K the Nernst equation gives

$$E = 1.10 \text{ V} - \frac{0.0592 \text{ V}}{2} \log \frac{[\text{Zn}^{2+}]}{[\text{Cu}^{2+}]} \quad [20.19]$$

Recall that pure solids are excluded from the expression for Q . ∞ (Section 15.6) According to Equation 20.19, the emf increases as $[\text{Cu}^{2+}]$ increases and as $[\text{Zn}^{2+}]$ decreases. For example, when $[\text{Cu}^{2+}]$ is 5.0 M and $[\text{Zn}^{2+}]$ is 0.050 M, we have

$$\begin{aligned} E &= 1.10 \text{ V} - \frac{0.0592 \text{ V}}{2} \log \left(\frac{0.050}{5.0} \right) \\ &= 1.10 \text{ V} - \frac{0.0592 \text{ V}}{2} (-2.00) = 1.16 \text{ V} \end{aligned}$$

Thus, increasing the concentration of reactant Cu^{2+} and decreasing the concentration of product Zn^{2+} relative to standard conditions increases the emf of the cell relative to standard conditions ($E^\circ = +1.10 \text{ V}$).

The Nernst equation helps us understand why the emf of a voltaic cell drops as the cell discharges. As reactants are converted to products, the value of Q increases, so the value of E decreases, eventually reaching $E = 0$. Because $\Delta G = -nFE$ (Equation 20.11), it follows that $\Delta G = 0$ when $E = 0$. Recall that a system is at equilibrium when $\Delta G = 0$. ∞ (Section 19.7) Thus, when $E = 0$, the cell reaction has reached equilibrium, and no net reaction occurs.

In general, increasing the concentration of reactants or decreasing the concentration of products increases the driving force for the reaction, resulting in a higher emf. Conversely, decreasing the concentration of reactants or increasing the concentration of products causes the emf to decrease from its value under standard conditions.

SAMPLE EXERCISE 20.11 Cell Potential under Nonstandard Conditions

Calculate the emf at 298 K generated by a voltaic cell in which the reaction is

when $[\text{Cr}_2\text{O}_7^{2-}] = 2.0 \text{ M}$, $[\text{H}^+] = 1.0 \text{ M}$, $[\text{I}^-] = 1.0 \text{ M}$, and $[\text{Cr}^{3+}] = 1.0 \times 10^{-5} \text{ M}$.

SOLUTION

Analyze We are given a chemical equation for a voltaic cell and the concentrations of reactants and products under which it operates. We are asked to calculate the emf of the cell under these nonstandard conditions.

Plan To calculate the emf of a cell under nonstandard conditions, we use the Nernst equation in the form of Equation 20.18.

Solve We calculate E° for the cell from standard reduction potentials (Table 20.1 or Appendix E). The standard emf for this reaction was calculated in Sample Exercise 20.6: $E^\circ = 0.79$ V. As that exercise shows, six electrons are transferred from reducing agent to oxidizing agent, so $n = 6$. The reaction quotient, Q , is

$$Q = \frac{[\text{Cr}^{3+}]^2}{[\text{Cr}_2\text{O}_7^{2-}][\text{H}^+]^{14}[\text{I}^-]^6} = \frac{(1.0 \times 10^{-5})^2}{(2.0)(1.0)^{14}(1.0)^6} = 5.0 \times 10^{-11}$$

Using Equation 20.18, we have

$$\begin{aligned} E &= 0.79 \text{ V} - \left(\frac{0.0592 \text{ V}}{6} \right) \log(5.0 \times 10^{-11}) \\ &= 0.79 \text{ V} - \left(\frac{0.0592 \text{ V}}{6} \right) (-10.30) \\ &= 0.79 \text{ V} + 0.10 \text{ V} = 0.89 \text{ V} \end{aligned}$$

Check This result is qualitatively what we expect: Because the concentration of $\text{Cr}_2\text{O}_7^{2-}$ (a reactant) is greater than 1 M and the concentration of Cr^{3+} (a product) is less than 1 M, the emf is greater than E° . Because Q is about 10^{-10} , $\log Q$ is about -10 . Thus, the correction to E° is about $0.06 \times 10/6$, which is 0.1, in agreement with the more detailed calculation.

PRACTICE EXERCISE

Calculate the emf generated by the cell described in the practice exercise accompanying Sample Exercise 20.6 when $[\text{Al}^{3+}] = 4.0 \times 10^{-3}$ M and $[\text{I}^-] = 0.010$ M.

Answer: $E = +2.36$ V

SAMPLE EXERCISE 20.12 Calculating Concentrations in a Voltaic Cell

If the potential of a Zn- H^+ cell (like that in Figure 20.9) is 0.45 V at 25 °C when $[\text{Zn}^{2+}] = 1.0$ M and $P_{\text{H}_2} = 1.0$ atm, what is the H^+ concentration?

SOLUTION

Analyze We are given a description of a voltaic cell, its emf, and the concentration of Zn^{2+} and the partial pressure of H_2 (both products in the cell reaction). We are asked to calculate the concentration of H^+ , a reactant.

Plan We write the equation for the cell reaction and use standard reduction potentials to calculate E° for the reaction. After determining the value of n from our reaction equation, we solve the Nernst equation, Equation 20.18, for Q . Finally, we use the equation for the cell reaction to write an expression for Q that contains $[\text{H}^+]$ to determine $[\text{H}^+]$.

Solve The cell reaction is

The standard emf is

$$\begin{aligned} E^\circ &= E_{\text{red}}^\circ(\text{reduction}) - E_{\text{red}}^\circ(\text{oxidation}) \\ &= 0 \text{ V} - (-0.76 \text{ V}) = +0.76 \text{ V} \end{aligned}$$

Because each Zn atom loses two electrons,

$$n = 2$$

Using Equation 20.18, we can solve for Q :

$$\begin{aligned} 0.45 \text{ V} &= 0.76 \text{ V} - \frac{0.0592 \text{ V}}{2} \log Q \\ Q &= 10^{10.5} = 3 \times 10^{10} \end{aligned}$$

Q has the form of the equilibrium constant for the reaction:

$$Q = \frac{[\text{Zn}^{2+}]P_{\text{H}_2}}{[\text{H}^+]^2} = \frac{(1.0)(1.0)}{[\text{H}^+]^2} = 3 \times 10^{10}$$

Solving for $[\text{H}^+]$, we have

$$\begin{aligned} [\text{H}^+]^2 &= \frac{1.0}{3 \times 10^{10}} = 3 \times 10^{-11} \\ [\text{H}^+] &= \sqrt{3 \times 10^{-11}} = 6 \times 10^{-6} \text{ M} \end{aligned}$$

Comment A voltaic cell whose cell reaction involves H^+ can be used to measure $[\text{H}^+]$ or pH. A pH meter is a specially designed voltaic cell with a voltmeter calibrated to read pH directly.  (Section 16.4)

PRACTICE EXERCISE

What is the pH of the solution in the cathode half-cell in Figure 20.9 when $P_{\text{H}_2} = 1.0$ atm, $[\text{Zn}^{2+}]$ in the anode half-cell is 0.10 M, and the cell emf is 0.542 V?

Answer: pH = 4.23 (using data from Appendix E to obtain E° to three significant figures)

Concentration Cells

In the voltaic cells we have looked at thus far, the reactive species at the anode has been different from the reactive species at the cathode. Cell emf depends on concentration, however, so a voltaic cell can be constructed using the *same* species in both half-cells as long as the concentrations are different. A cell based solely on the emf generated because of a difference in a concentration is called a **concentration cell**.

An example of a concentration cell is diagrammed in ▼ FIGURE 20.15(a). One half-cell consists of a strip of nickel metal immersed in a $1.00 \times 10^{-3} M$ solution of $\text{Ni}^{2+}(aq)$. The other half-cell also has an $\text{Ni}(s)$ electrode, but it is immersed in a $1.00 M$ solution of $\text{Ni}^{2+}(aq)$. The two half-cells are connected by a salt bridge and by an external wire running through a voltmeter. The half-cell reactions are the reverse of each other:

Although the *standard* emf for this cell is zero,

$$E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode}) = (-0.28 \text{ V}) - (-0.28 \text{ V}) = 0 \text{ V}$$

the cell operates under *nonstandard* conditions because the concentration of $\text{Ni}^{2+}(aq)$ is not $1 M$ in both half-cells. In fact, the cell operates until $[\text{Ni}^{2+}]_{\text{anode}} = [\text{Ni}^{2+}]_{\text{cathode}}$. Oxidation of $\text{Ni}(s)$ occurs in the half-cell containing the more dilute solution, which means this is the anode of the cell. Reduction of $\text{Ni}^{2+}(aq)$ occurs in the half-cell containing the more concentrated solution, making it the cathode. The *overall* cell reaction is therefore

We can calculate the emf of a concentration cell by using the Nernst equation. For this particular cell, we see that $n = 2$. The expression for the reaction quotient for the overall reaction is $Q = [\text{Ni}^{2+}]_{\text{dilute}}/[\text{Ni}^{2+}]_{\text{concentrated}}$. Thus, the emf at 298 K is

$$\begin{aligned} E &= E^{\circ} - \frac{0.0592 \text{ V}}{n} \log Q \\ &= 0 - \frac{0.0592 \text{ V}}{2} \log \frac{[\text{Ni}^{2+}]_{\text{dilute}}}{[\text{Ni}^{2+}]_{\text{concentrated}}} = -\frac{0.0592 \text{ V}}{2} \log \frac{1.00 \times 10^{-3} M}{1.00 M} \\ &= +0.0888 \text{ V} \end{aligned}$$

GO FIGURE

Assuming that the solutions are made from $\text{Ni}(\text{NO}_3)_2$, how do the ions migrate as the cell operates?

▲ FIGURE 20.15 Concentration cell based on the Ni^{2+} -Ni cell reaction. (a) Concentrations of $\text{Ni}^{2+}(aq)$ in the two half-cells are unequal, and the cell generates an electrical current. (b) The cell operates until $[\text{Ni}^{2+}(aq)]$ is the same in the two half-cells, at which point the cell has reached equilibrium and is “dead.”

This concentration cell generates an emf of nearly 0.09 V even though $E^\circ = 0$. The difference in concentration provides the driving force for the cell. When the concentrations in the two half-cells become the same, $Q = 1$ and $E = 0$.

The idea of generating a potential by a concentration difference is the basis for the operation of pH meters. It is also a critical aspect in biology. For example, nerve cells in the brain generate a potential across the cell membrane by having different concentrations of ions on the two sides of the membrane. The regulation of the heartbeat in mammals, as discussed in the following “Chemistry and Life” box, is another example of the importance of electrochemistry to living organisms.

CHEMISTRY AND LIFE

HEARTBEATS AND ELECTROCARDIOGRAPHY

The human heart is a marvel of efficiency and dependability. In a typical day an adult's heart pumps more than 7000 L of blood through the circulatory system, usually with no maintenance required beyond a sensible diet and lifestyle. We generally think of the heart as a mechanical device, a muscle that circulates blood via regularly spaced muscular contractions. However, more than two centuries ago, two pioneers in electricity, Luigi Galvani (1729–1787) and Alessandro Volta (1745–1827), discovered that the contractions of the heart are controlled by electrical phenomena, as are nerve impulses throughout the body. The pulses of electricity that cause the heart to beat result from a remarkable combination of electrochemistry and the properties of semipermeable membranes. ∞ (Section 13.5)

Cell walls are membranes with variable permeability with respect to a number of physiologically important ions (especially Na^+ , K^+ , and Ca^{2+}). The concentrations of these ions are different for the fluids inside the cells (the *intracellular fluid*, or ICF) and outside the cells (the *extracellular fluid*, or ECF). In cardiac muscle cells, for example, the concentrations of K^+ in the ICF and ECF are typically about 135 millimolar (mM) and 4 mM, respectively. For Na^+ , however, the concentration difference between the ICF and ECF is opposite that for K^+ ; typically, $[\text{Na}^+]_{\text{ICF}} = 10 \text{ mM}$ and $[\text{Na}^+]_{\text{ECF}} = 145 \text{ mM}$.

The cell membrane is initially permeable to K^+ ions but is much less so to Na^+ and Ca^{2+} . The difference in concentration of K^+ ions between the ICF and ECF generates a concentration cell: Even though the same ions are present on both sides of the membrane, there is a potential difference between the two fluids that we can calculate using the Nernst equation with $E^\circ = 0$. At physiological temperature (37 °C) the potential in millivolts for moving K^+ from the ECF to the ICF is

$$\begin{aligned} E &= E^\circ - \frac{2.30 RT}{nF} \log \frac{[\text{K}^+]_{\text{ICF}}}{[\text{K}^+]_{\text{ECF}}} \\ &= 0 - (61.5 \text{ mV}) \log \left(\frac{135 \text{ mM}}{4 \text{ mM}} \right) = -94 \text{ mV} \end{aligned}$$

In essence, the interior of the cell and the ECF together serve as a voltaic cell. The negative sign for the potential indicates that work is required to move K^+ into the intracellular fluid.

Changes in the relative concentrations of the ions in the ECF and ICF lead to changes in the emf of the voltaic cell. The cells of the heart that govern the rate of heart contraction are called the *pacemaker cells*. The membranes of the cells regulate the concentrations of ions in the ICF, allowing them to change in a systematic way. The concentration changes cause the emf to change in a cyclic fashion, as shown

▲ **FIGURE 20.16** Changes in electrical potential in the human heart. Variation of the electrical potential caused by changes of ion concentrations in the pacemaker cells of the heart.

in ▲ **FIGURE 20.16**. The emf cycle determines the rate at which the heart beats. If the pacemaker cells malfunction because of disease or injury, an artificial pacemaker can be surgically implanted. The artificial pacemaker contains a small battery that generates the electrical pulses needed to trigger the contractions of the heart.

During the late 1800s, scientists discovered that the electrical impulses that cause the contraction of the heart muscle are strong enough to be detected at the surface of the body. This observation formed the basis for *electrocardiography*, noninvasive monitoring of the heart by using a complex array of electrodes on the skin to measure voltage changes during heartbeats. A typical electrocardiogram is shown in ▼ **FIGURE 20.17**. It is quite striking that, although the heart's major function is the *mechanical* pumping of blood, it is most easily monitored by using the *electrical* impulses generated by tiny voltaic cells.

▲ **FIGURE 20.17** A typical electrocardiogram. The printout records the electrical events monitored by electrodes attached to the body surface.

SAMPLE EXERCISE 20.13 Determining pH Using a Concentration Cell

A voltaic cell is constructed with two hydrogen electrodes. Electrode 1 has $P_{\text{H}_2} = 1.00$ atm and an unknown concentration of $\text{H}^+(aq)$. Electrode 2 is a standard hydrogen electrode ($P_{\text{H}_2} = 1.00$ atm, $[\text{H}^+] = 1.00$ M). At 298 K the measured cell potential is 0.211 V, and the electrical current is observed to flow from electrode 1 through the external circuit to electrode 2. Calculate $[\text{H}^+]$ for the solution at electrode 1. What is the pH of the solution?

SOLUTION

Analyze We are given the potential of a concentration cell and the direction in which the current flows. We also have the concentrations or partial pressures of all reactants and products except for $[\text{H}^+]$ in half-cell 1, which is our unknown.

Plan We can use the Nernst equation to determine Q and then use Q to calculate the unknown concentration. Because this is a concentration cell, $E_{\text{cell}}^\circ = 0$ V.

Solve Using the Nernst equation, we have $0.211 \text{ V} = 0 - \frac{0.0592 \text{ V}}{2} \log Q$

$$\log Q = -(0.211 \text{ V}) \left(\frac{2}{0.0592 \text{ V}} \right) = -7.13$$

$$Q = 10^{-7.13} = 7.4 \times 10^{-8}$$

Because electrons flow from electrode 1 to electrode 2, electrode 1 is the anode of the cell and electrode 2 is the cathode. The electrode reactions are therefore as follows, with the concentration of $\text{H}^+(aq)$ in electrode 1 represented with the unknown x :

Thus,

$$Q = \frac{[\text{H}^+(\text{aq}, x \text{ M})]^2}{[\text{H}^+(\text{aq}, 1.00 \text{ M})]^2}$$

$$= \frac{x^2}{(1.00)^2} = x^2 = 7.4 \times 10^{-8}$$

$$x = [\text{H}^+] = \sqrt{7.4 \times 10^{-8}} = 2.7 \times 10^{-4}$$

At electrode 1, therefore, the pH of the solution is

$$\text{pH} = -\log[\text{H}^+] = -\log(2.7 \times 10^{-4}) = 3.57$$

Comment The concentration of H^+ at electrode 1 is lower than that in electrode 2, which is why electrode 1 is the anode of the cell: The oxidation of H_2 to $\text{H}^+(aq)$ increases $[\text{H}^+]$ at electrode 1.

PRACTICE EXERCISE

A concentration cell is constructed with two $\text{Zn}(s) - \text{Zn}^{2+}(aq)$ half-cells. In one half-cell $[\text{Zn}^{2+}] = 1.35$ M, and in the other $[\text{Zn}^{2+}] = 3.75 \times 10^{-4}$ M. (a) Which half-cell is the anode? (b) What is the emf of the cell?

Answers: (a) the half-cell in which $[\text{Zn}^{2+}] = 3.75 \times 10^{-4}$ M, (b) 0.105 V

**20.7 BATTERIES AND FUEL CELLS**

A **battery** is a portable, self-contained electrochemical power source that consists of one or more voltaic cells. For example, the 1.5-V batteries used to power flashlights and many consumer electronic devices are single voltaic cells. Greater voltages can be achieved by using multiple cells, as in 12-V automotive batteries. When cells are connected in series (which means the cathode of one attached to the anode of another), the battery produces a voltage that is the sum of the voltages of the individual cells. Higher voltages can also be achieved by using multiple batteries in series (◀ **FIGURE 20.18**). Battery electrodes are marked following the convention of Figure 20.6—plus for cathode and minus for anode.

◀ **FIGURE 20.18** Combining batteries. When batteries are connected in series, as in most flashlights, the total voltage is the sum of the individual voltages.

Although any spontaneous redox reaction can serve as the basis for a voltaic cell, making a commercial battery that has specific performance characteristics can require considerable ingenuity. The substances oxidized at the anode and reduced by the cathode determine the voltage, and the usable life of the battery depends on the quantities of these substances packaged in the battery. Usually a barrier analogous to the porous barrier of Figure 20.6 separates the anode and cathode half-cells.

Different applications require batteries with different properties. The battery required to start a car, for example, must be capable of delivering a large electrical current for a short time period, whereas the battery that powers a heart pacemaker must be very small and capable of delivering a small but steady current over an extended time period. Some batteries are *primary* cells, meaning they cannot be recharged and must be either discarded or recycled after the voltage drops to zero. A *secondary* cell can be recharged from an external power source after its voltage has dropped.

As we consider some common batteries, notice how the principles we have discussed so far help us understand these important sources of portable electrical energy.

Lead-Acid Battery

A 12-V lead-acid automotive battery consists of six voltaic cells in series, each producing 2 V. The cathode of each cell is lead dioxide (PbO_2) packed on a lead grid (► FIGURE 20.19). The anode of each cell is lead. Both electrodes are immersed in sulfuric acid.

The reactions that occur during discharge are

The standard cell potential can be obtained from the standard reduction potentials in Appendix E:

$$E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode}) = (+1.685 \text{ V}) - (-0.356 \text{ V}) = +2.041 \text{ V}$$

The reactants Pb and PbO_2 are the electrodes. Because these reactants are solids, there is no need to separate the cell into half-cells; the Pb and PbO_2 cannot come into contact with each other unless one electrode touches another. To keep the electrodes from touching, wood or glass-fiber spacers are placed between them (Figure 20.19). Using a reaction whose reactants and products are solids has another benefit. Because solids are excluded from the reaction quotient Q , the relative amounts of $\text{Pb}(s)$, $\text{PbO}_2(s)$, and $\text{PbSO}_4(s)$ have no effect on the voltage of the lead storage battery, helping the battery maintain a relatively constant voltage during discharge. The voltage does vary somewhat with use because the concentration of H_2SO_4 varies with the extent of discharge. As Equation 20.20 indicates, H_2SO_4 is consumed during the discharge.

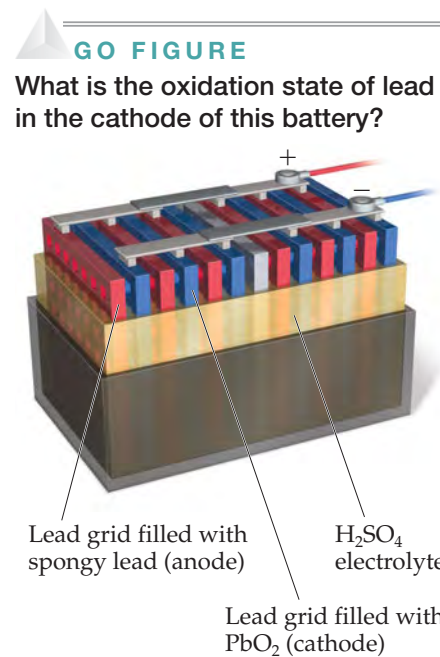

A major advantage of the lead-acid battery is that it can be recharged. During recharging, an external source of energy is used to reverse the direction of the cell reaction, regenerating $\text{Pb}(s)$ and $\text{PbO}_2(s)$:

In an automobile the alternator provides the energy necessary for recharging the battery. Recharging is possible because PbSO_4 formed during discharge adheres to the electrodes. As the external source forces electrons from one electrode to the other, the PbSO_4 is converted to Pb at one electrode and to PbO_2 at the other.

Alkaline Battery

The most common primary (nonrechargeable) battery is the alkaline battery (► FIGURE 20.20). The anode is powdered zinc metal immobilized in a gel in contact with a concentrated solution of KOH (hence, the name *alkaline* battery). The cathode is a mixture of

▲ FIGURE 20.19 A 12-V automotive lead-acid battery. Each anode/cathode pair in this schematic cutaway produces a voltage of about 2 V. Six pairs of electrodes are connected in series, producing 12 V.

▲ FIGURE 20.20 Cutaway view of a miniature alkaline battery.

$\text{MnO}_2(\text{s})$ and graphite, separated from the anode by a porous fabric. The battery is sealed in a steel can to reduce the risk of any of the concentrated KOH escaping.

The cell reactions are complex but can be approximately represented as follows:

Nickel-Cadmium, Nickel-Metal-Hydride, and Lithium-Ion Batteries

The tremendous growth in high-power-demand portable electronic devices in the last decade has increased the demand for lightweight, readily recharged batteries. One of the most common rechargeable batteries is the nickel-cadmium (nicad) battery. During discharge, cadmium metal is oxidized at the anode while nickel oxyhydroxide [$\text{NiO}(\text{OH})(\text{s})$] is reduced at the cathode:

As in the lead-acid battery, the solid reaction products adhere to the electrodes, which permits the electrode reactions to be reversed during charging. A single nicad voltaic cell has a voltage of 1.30 V. Nicad battery packs typically contain three or more cells in series to produce the higher voltages needed by most electronic devices.

Two drawbacks to nickel-cadmium batteries are that cadmium is both toxic and dense. Its use increases battery weight and provides an environmental hazard—roughly 1.5 billion nickel-cadmium batteries are produced annually, and these must eventually be recycled as they lose their ability to be recharged. Some of the problem has been alleviated by the development of the nickel-metal-hydride (NiMH) battery. The cathode reaction is the same as that for nickel-cadmium batteries, but the anode reaction is very different. The anode consists of a metal *alloy*, such as ZrNi_2 , that has the ability to absorb hydrogen atoms. During oxidation at the anode, the hydrogen atoms lose electrons, and the resultant H^+ ions react with OH^- ions to form H_2O , a process that is reversed during charging.

The current generation of hybrid gas–electric automobiles use NiMH batteries, which are recharged by the electric motor while braking. These batteries can last up to 8 years.

The newest rechargeable battery to receive large use in consumer devices is the lithium-ion (Li-ion) battery. You will find this battery in cell phones and laptop computers. Because lithium is a very light element, Li-ion batteries achieve a greater *energy density*—the amount of energy stored per unit mass—than nickel-based batteries. The technology of Li-ion batteries is based on the ability of Li^+ ions to be inserted into and removed from certain layered solids. For example, Li^+ ions can be inserted reversibly into layers of graphite (Figure 12.30). In most commercial cells, one electrode is graphite or some other carbon-based material, and the other is usually made of lithium cobalt oxide (LiCoO_2). When the cell is charged, cobalt ions are oxidized and Li^+ ions migrate into the graphite. During discharge, when the battery is producing electricity for use, the Li^+ ions spontaneously migrate from the graphite anode to the cathode, enabling electrons to flow through the external circuit. An Li-ion battery produces a maximum voltage of 3.7 V, considerably higher than typical 1.5-V alkaline batteries.

Hydrogen Fuel Cells

The thermal energy released by burning fuels can be converted to electrical energy. The thermal energy may convert water to steam, for instance, which drives a turbine that in turn drives an electrical generator. Typically, a maximum of only 40% of the energy from combustion is converted to electricity in this manner; the remainder is lost as heat. The direct production of electricity from fuels by a voltaic cell could, in principle, yield a higher rate of conversion of chemical energy to electrical energy. Voltaic cells that perform this conversion using conventional fuels, such as H_2 and CH_4 , are called **fuel cells**. Strictly speaking, fuel cells are *not* batteries because they are not self-contained systems—the fuel must be continuously supplied to generate electricity.

The most common fuel-cell systems involve the reaction of $\text{H}_2(\text{g})$ and $\text{O}_2(\text{g})$ to form $\text{H}_2\text{O}(\text{l})$. These cells can generate electricity twice as efficiently as the best internal combustion engine. Under acidic conditions, the reactions are

These cells employ hydrogen gas as the fuel and oxygen gas from air as the oxidant and generate about 1 V.

Fuel cells are often named for either the fuel or the electrolyte used. In the hydrogen-PEM fuel cell (the acronym PEM stands for either proton-exchange membrane or polymer-electrolyte membrane), the anode and cathode are separated by a membrane, which is permeable to protons but not to electrons (► FIGURE 20.21). The membrane therefore acts as a salt bridge. The electrodes are typically made from graphite.

The hydrogen-PEM cell operates at around 80°C . At this temperature the electrochemical reactions would normally occur very slowly, and so a thin layer of platinum on each electrode catalyzes the reactions. Many fuel cells require much higher temperatures to operate.

In order to power a vehicle, multiple cells must be assembled into a fuel cell *stack*. The amount of power generated by a stack depends on the number and size of the fuel cells in the stack and on the surface area of the PEM.

Much fuel cell research today is directed toward improving electrolytes and catalysts and toward developing cells that use fuels such as hydrocarbons and alcohols, which are not as difficult to handle and distribute as hydrogen gas.

▲ FIGURE 20.21 A hydrogen-PEM fuel cell. The proton-exchange membrane (PEM) allows H^+ ions generated by H_2 oxidation at the anode to migrate to the cathode, where H_2O is formed.

CHEMISTRY PUT TO WORK

Direct Methanol Fuel Cells

Even though the hydrogen fuel cell is highly developed, liquid methanol, CH_3OH , is a far more attractive fuel to store and transport than hydrogen gas. Furthermore, methanol is a clean-burning liquid, and its use would require only minor modifications to existing engines and to fuel-delivery infrastructure.

One of the intriguing aspects of methanol fuel is that manufacturing it could consume carbon dioxide, a source of global warming. (Section 18.2) Methanol can be made by combining CO_2 and H_2 , although the process is presently costly. Imagine, though, that the synthesis can be improved and that the CO_2 used in the synthesis is captured from exhaust gases from power plants or even directly from the atmosphere. In such cases, the CO_2 released by subsequently burning the methanol would be canceled by the carbon dioxide captured to make it. Thus, the process would be

carbon neutral, meaning that it would not increase the concentration of CO_2 in the atmosphere. The prospect of a liquid fuel that could replace conventional fuels without contributing to the greenhouse effect has spurred considerable research to reduce the cost of methanol synthesis and to develop and improve methanol fuel cell technology.

A direct methanol fuel cell has been developed that is similar to the hydrogen-PEM fuel cell. The reactions in the cell are

The direct methanol fuel cell is currently too expensive and too inefficient to be used in passenger cars. Nevertheless, small methanol fuel cells could appear in mobile devices such as computers or cell phones in the near future.

20.8 CORROSION

In this section we examine the undesirable redox reactions that lead to **corrosion** of metals. Corrosion reactions are spontaneous redox reactions in which a metal is attacked by some substance in its environment and converted to an unwanted compound.

For nearly all metals, oxidation is thermodynamically favorable in air at room temperature. When oxidation of a metal object is not inhibited, it can destroy the object. Oxidation can form an insulating protective oxide layer, however, that prevents further reaction of the underlying metal. Based on the standard reduction potential for Al^{3+} , for example, we expect aluminum metal to be readily oxidized. The many aluminum soft-drink and beer cans that litter the environment are ample evidence, however, that

aluminum undergoes only very slow chemical corrosion. The exceptional stability of this active metal in air is due to the formation of a thin protective coat of oxide—a hydrated form of Al_2O_3 —on the metal surface. The oxide coat is impermeable to O_2 or H_2O and so protects the underlying metal from further corrosion.

Magnesium metal is similarly protected, and some metal alloys, such as stainless steel, likewise form protective impervious oxide coats.

Corrosion of Iron (Rusting)

The rusting of iron is a familiar corrosion process that carries a significant economic impact. Up to 20% of the iron produced annually in the United States is used to replace iron objects that have been discarded because of rust damage.

Rusting of iron requires both oxygen and water, and the process can be accelerated by other factors such as pH, presence of salts, contact with metals more difficult to oxidize than iron, and stress on the iron. The corrosion process involves oxidation and reduction, and the metal conducts electricity. Thus, electrons can move through the metal from a region where oxidation occurs to a region where reduction occurs, as in voltaic cells. Because the standard reduction potential for reduction of $\text{Fe}^{2+}(\text{aq})$ is less positive than that for reduction of O_2 , $\text{Fe}(\text{s})$ can be oxidized by $\text{O}_2(\text{g})$:

A portion of the iron, often associated with a dent or region of strain, can serve as an anode at which Fe is oxidized to Fe^{2+} (▼ FIGURE 20.22). The electrons produced in the oxidation migrate through the metal from this anodic region to another portion of the surface, which serves as the cathode where O_2 is reduced. The reduction of O_2 requires H^+ , so lowering the concentration of H^+ (increasing the pH) makes O_2 reduction less favorable. Iron in contact with a solution whose pH is greater than 9 does not corrode.

The Fe^{2+} formed at the anode is eventually oxidized to Fe^{3+} , which forms the hydrated iron(III) oxide known as rust:*

GO FIGURE

What is the oxidizing agent in this corrosion reaction?

► **FIGURE 20.22** Corrosion of iron in contact with water. One region of the iron acts as the cathode and another region acts as the anode.

*Frequently, metal compounds obtained from aqueous solution have water associated with them. For example, copper(II) sulfate crystallizes from water with 5 mol of water per mole of CuSO_4 . We represent this substance by the formula $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$. Such compounds are called hydrates. ∞ (Section 13.1) Rust is a hydrate of iron(III) oxide with a variable amount of water of hydration. We represent this variable water content by writing the formula $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$.

◀ **FIGURE 20.23** Cathodic protection of iron in contact with zinc. The standard reduction potentials are $E_{\text{red, Fe}^{2+}}^{\circ} = -0.440 \text{ V}$, $E_{\text{red, Zn}^{2+}}^{\circ} = -0.763 \text{ V}$, making the zinc more readily oxidized.

Because the cathode is generally the area having the largest supply of O_2 , rust often deposits there. If you look closely at a shovel after it has stood outside in the moist air with wet dirt adhered to its blade, you may notice that pitting has occurred under the dirt but that rust has formed elsewhere, where O_2 is more readily available. The enhanced corrosion caused by the presence of salts is usually evident on autos in areas where roads are heavily salted during winter. Like a salt bridge in a voltaic cell, the ions of the salt provide the electrolyte necessary to complete the electrical circuit.

Preventing Corrosion of Iron

Objects made of iron are often covered with a coat of paint or another metal to protect against corrosion. Covering the surface with paint prevents oxygen and water from reaching the iron surface. If the coating is broken, however, and the iron exposed to oxygen and water, corrosion begins as the iron is oxidized.

With *galvanized iron*, which is iron coated with a thin layer of zinc, the iron is protected from corrosion even after the surface coat is broken. The standard reduction potentials are

Because E_{red}° for Fe^{2+} is less negative (more positive) than E_{red}° for Zn^{2+} , $\text{Zn}(\text{s})$ is more readily oxidized than $\text{Fe}(\text{s})$. Thus, even if the zinc coating is broken and the galvanized iron is exposed to oxygen and water, as in **▲ FIGURE 20.23**, the zinc serves as the anode and is corroded (oxidized) instead of the iron. The iron serves as the cathode at which O_2 is reduced.

Protecting a metal from corrosion by making it the cathode in an electrochemical cell is known as **cathodic protection**. The metal that is oxidized while protecting the cathode is called the *sacrificial anode*. Underground pipelines and storage tanks made of iron are often protected against corrosion by making the iron the cathode of a voltaic cell. For example, pieces of a metal that is more easily oxidized than iron, such as magnesium ($E_{\text{red}}^{\circ} = -2.37 \text{ V}$), are buried near the pipe or storage tank and connected to it by wire (**► FIGURE 20.24**). In moist soil, where corrosion can occur, the sacrificial metal serves as the anode, and the pipe or tank experiences cathodic protection.

▲ **FIGURE 20.24** Cathodic protection of an iron pipe. A mixture of gypsum, sodium sulfate, and clay surrounds the sacrificial magnesium anode to promote conductivity of ions.

▲ GIVE IT SOME THOUGHT

Based on the values in Table 20.1, which of these metals could provide cathodic protection to iron: Al, Cu, Ni, Zn?

▲ **FIGURE 20.25** Electrolysis of molten sodium chloride. Pure NaCl melts at 801 °C.

20.9 | ELECTROLYSIS

Voltaic cells are based on spontaneous redox reactions. It is also possible for *nonspontaneous* redox reactions to occur, however, by using electrical energy to drive them. For example, electricity can be used to decompose molten sodium chloride into its component elements Na and Cl₂. Such processes driven by an outside source of electrical energy are called **electrolysis reactions** and take place in **electrolytic cells**.

An electrolytic cell consists of two electrodes immersed either in a molten salt or in a solution. A battery or some other source of electrical energy acts as an electron pump, pushing electrons into one electrode and pulling them from the other. Just as in voltaic cells, the electrode at which reduction occurs is called the cathode, and the electrode at which oxidation occurs is called the anode.

In the electrolysis of molten NaCl, Na⁺ ions pick up electrons and are reduced to Na at the cathode ◀ **FIGURE 20.25**. As Na⁺ ions near the cathode are depleted, additional Na⁺ ions migrate in. Similarly, there is net movement of Cl⁻ ions to the anode where they are oxidized. The electrode reactions for the electrolysis are

Notice how the energy source is connected to the electrodes in Figure 20.25. The positive terminal is connected to the anode and the negative terminal is connected to the cathode, which forces electrons to move from the anode to the cathode.

Because of the high melting points of ionic substances, the electrolysis of molten salts requires very high temperatures. Do we obtain the same products if we electrolyze the aqueous solution of a salt instead of the molten salt? Frequently the answer is no because water itself might be oxidized to form O₂ or reduced to form H₂ rather than the ions of the salt.

In our examples of the electrolysis of NaCl, the electrodes are *inert*; they do not react but merely serve as the surface where oxidation and reduction occur. Several practical applications of electrochemistry, however, are based on *active* electrodes—electrodes that participate in the electrolysis process. *Electroplating*, for example, uses electrolysis to deposit a thin layer of one metal on another metal to improve beauty or resistance to corrosion. Examples include electroplating nickel or chromium onto steel and electroplating a precious metal like silver onto a less expensive one.

◀ **FIGURE 20.26** illustrates an electrolytic cell for electroplating nickel onto a piece of steel. The anode is a strip of nickel metal, and the cathode is the steel. The electrodes

are immersed in a solution of NiSO₄(aq). When an external voltage is applied, reduction occurs at the cathode. The standard reduction potential of Ni²⁺ ($E_{\text{red}}^\circ = -0.28 \text{ V}$) is less negative than that of H₂O ($E_{\text{red}}^\circ = -0.83 \text{ V}$), so Ni²⁺ is preferentially reduced, depositing a layer of nickel metal on the steel cathode.

At the anode, the nickel metal is oxidized. To explain this behavior, we need to compare the substances in contact with the anode, H₂O and NiSO₄(aq), with the anode material, Ni. For the NiSO₄(aq) solution, neither Ni²⁺ nor SO₄²⁻ can be oxidized (because both already have their elements in their highest possible oxidation state). The H₂O solvent and the Ni atoms in the anode, however, can both undergo oxidation:

We saw in Section 20.4 that the half-reaction with the more negative E_{red}° undergoes oxidation more readily. (Remember Figure 20.12: The strongest reducing agents, which are the substances oxidized most readily, have the most negative E_{red}° values.)

▲ **FIGURE 20.26** Electrolytic cell with an active metal electrode. Nickel dissolves from the anode to form Ni²⁺(aq). At the cathode Ni²⁺(aq) is reduced and forms a nickel “plate” on the steel cathode.

Thus, it is the Ni(s), with its $E_{\text{red}}^{\circ} = -0.28 \text{ V}$, that is oxidized at the anode rather than the H_2O . If we look at the overall reaction, it appears as if nothing has been accomplished. However, this is not true because Ni atoms are transferred from the Ni anode to the steel cathode, plating the steel with a thin layer of nickel atoms.

The standard emf for the overall reaction is

$$E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode}) = (-0.28 \text{ V}) - (-0.28 \text{ V}) = 0$$

Because the standard emf is zero, only a small emf is needed to cause the transfer of nickel atoms from one electrode to the other.

Quantitative Aspects of Electrolysis

The stoichiometry of a half-reaction shows how many electrons are needed to achieve an electrolytic process. For example, the reduction of Na^+ to Na is a one-electron process:

Thus, 1 mol of electrons plates out 1 mol of Na metal, 2 mol of electrons plate out 2 mol of Na metal, and so forth. Similarly, 2 mol of electrons are required to produce 1 mol of Cu from Cu^{2+} , and 3 mol of electrons are required to produce 1 mol of Al from Al^{3+} :

For any half-reaction, the amount of substance reduced or oxidized in an electrolytic cell is directly proportional to the number of electrons passed into the cell.

The quantity of charge passing through an electrical circuit, such as that in an electrolytic cell, is generally measured in *coulombs*. As noted in Section 20.5, the charge on 1 mol of electrons is 96,485 C. A coulomb is the quantity of charge passing a point in a circuit in 1 s when the current is 1 ampere (A). Therefore, the number of coulombs passing through a cell can be obtained by multiplying the current in amperes by the elapsed time in seconds.

$$\text{Coulombs} = \text{amperes} \times \text{seconds} \quad [20.21]$$

► **FIGURE 20.27** shows how the quantities of substances produced or consumed in electrolysis are related to the quantity of electrical charge used. The same relationships can also be applied to voltaic cells. In other words, electrons can be thought of as “reagents” in electrolysis reactions.

▲ **FIGURE 20.27** Relationship between charge and amount of reactant and product in electrolysis reactions.

SAMPLE EXERCISE 20.14 Relating Electrical Charge and Quantity of Electrolysis

Calculate the number of grams of aluminum produced in 1.00 h by the electrolysis of molten AlCl_3 if the electrical current is 10.0 A.

SOLUTION

Analyze We are told that AlCl_3 is electrolyzed to form Al and asked to calculate the number of grams of Al produced in 1.00 h with 10.0 A.

Plan Figure 20.27 provides a road map for this problem. First, the product of the amperage and the time in seconds gives the number of coulombs of electrical charge being used (Equation 20.21). Second, the coulombs can be converted with Faraday’s constant ($F = 96,485 \text{ C/mol electrons}$) to tell us the number of moles of

electrons being supplied. Third, reduction of 1 mol of Al^{3+} to Al requires 3 mol of electrons. Hence, we can use the number of moles of electrons to calculate the number of moles of Al metal it produces. Finally, we convert moles of Al into grams.

Solve First, we calculate the coulombs of electrical charge passed into the electrolytic cell:

$$\text{Coulombs} = \text{amperes} \times \text{seconds} = (10.0 \text{ A})(1.00 \text{ h}) \left(\frac{3600 \text{ s}}{\text{h}} \right) = 3.60 \times 10^4 \text{ C}$$

Second, we calculate the number of moles of electrons that pass into the cell:

$$\text{Moles } \text{e}^- = (3.60 \times 10^4 \text{ C}) \left(\frac{1 \text{ mol } \text{e}^-}{96,485 \text{ C}} \right) = 0.373 \text{ mol } \text{e}^-$$

Third, we relate number of moles of electrons to number of moles of aluminum formed, using the half-reaction for the reduction of Al^{3+} :

Thus, 3 mol of electrons are required to form 1 mol of Al:

$$\text{Moles Al} = (0.373 \text{ mol e}^-) \left(\frac{1 \text{ mol Al}}{3 \text{ mol e}^-} \right) = 0.124 \text{ mol Al}$$

Finally, we convert moles to grams:

$$\text{Grams Al} = (0.124 \text{ mol Al}) \left(\frac{27.0 \text{ g Al}}{1 \text{ mol Al}} \right) = 3.36 \text{ g Al}$$

Because each step involves multiplication by a new factor, we can combine all the steps:

$$\text{Grams Al} = (3.60 \times 10^4 \text{ C}) \left(\frac{1 \text{ mole e}^-}{96,485 \text{ C}} \right) \left(\frac{1 \text{ mol Al}}{3 \text{ mol e}^-} \right) \left(\frac{27.0 \text{ g Al}}{1 \text{ mol Al}} \right) = 3.36 \text{ g Al}$$

PRACTICE EXERCISE

(a) The half-reaction for formation of magnesium metal upon electrolysis of molten MgCl_2 is $\text{Mg}^{2+} + 2 \text{e}^- \longrightarrow \text{Mg}$. Calculate the mass of magnesium formed upon passage of a current of 60.0 A for a

Answers: (a) 30.2 g of Mg, (b) 3.97×10^3 s

period of 4.00×10^3 s. (b) How many seconds would be required to produce 50.0 g of Mg from MgCl_2 if the current is 100.0 A?

CHEMISTRY PUT TO WORK

Electrometallurgy of Aluminum

Many processes used to produce or refine metals are based on electrolysis. Collectively these processes are referred to as *electrometallurgy*. Electrometallurgical procedures can be broadly differentiated according to whether they involve electrolysis of a molten salt or of an aqueous solution.

Electrolytic methods using molten salts are important for obtaining the more active metals, such as sodium, magnesium, and aluminum. These metals cannot be obtained from aqueous solution because water is more easily reduced than the metal ions. The standard reduction potentials of water under both acidic ($E_{\text{red}}^\circ = 0.00 \text{ V}$) and basic ($E_{\text{red}}^\circ = -0.83 \text{ V}$) conditions are more positive than those of Na^+ ($E_{\text{red}}^\circ = -2.71 \text{ V}$), Mg^{2+} ($E_{\text{red}}^\circ = -2.37 \text{ V}$), and Al^{3+} ($E_{\text{red}}^\circ = -1.66 \text{ V}$).

Historically, obtaining aluminum metal has been a challenge. It is obtained from bauxite ore, which is chemically treated to concentrate aluminum oxide (Al_2O_3). The melting point of aluminum oxide is above 2000°C , which is too high to permit its use as a molten medium for electrolysis.

The electrolytic process used commercially to produce aluminum is the *Hall-Hérault process*, named after its inventors, Charles M. Hall and Paul Hérault. Hall (▼ FIGURE 20.28) began working on the problem of reducing aluminum in about 1885 after he had learned from a professor of the difficulty of reducing ores of very active metals. Before the development of an electrolytic process, aluminum was obtained by a chemical reduction using sodium or potassium as the reducing agent, a costly procedure that made aluminum metal expensive. As late as 1852, the cost of aluminum was \$545 per pound, far greater than the cost of gold. During the Paris Exposition in 1855, aluminum was exhibited as a rare metal, even though it is the third most abundant element in Earth's crust.

▼ FIGURE 20.28 Charles M. Hall (1863–1914) as a young man.

◀ FIGURE 20.29 The Hall-Hérault process. Because molten aluminum is denser than the mixture of cryolite (Na_3AlF_6) and Al_2O_3 , the metal collects at the bottom of the cell.

Hall, who was 21 years old when he began his research, utilized handmade and borrowed equipment in his studies and used a woodshed near his Ohio home as his laboratory. In about a year's time he developed an electrolytic procedure using an ionic compound that melts to form a conducting medium that dissolves Al_2O_3 but does not interfere with the electrolysis reactions. The ionic compound he selected was the relatively rare mineral cryolite (Na_3AlF_6). Hérault, who was the same age as Hall, independently made the same discovery in France at about the same time. Because of the research of these two unknown young scientists, large-scale production of aluminum became commercially feasible, and aluminum became a common and familiar metal. Indeed, the factory that Hall subsequently built to produce aluminum evolved into Alcoa Corporation.

In the Hall-Hérault process, Al_2O_3 is dissolved in molten cryolite, which melts at 1012°C and is an effective electrical conductor (▲ FIGURE 20.29). Graphite rods are employed as anodes and are consumed in the electrolysis:

A large amount of electrical energy is needed in the Hall-Hérault process with the result that the aluminum industry consumes about 2% of the electrical energy generated in the United States. Because recycled aluminum requires only 5% of the energy needed to produce “new” aluminum, considerable energy savings can be realized by increasing the amount of aluminum recycled. Approximately 42% of postconsumer aluminum is recycled in the United States.

SAMPLE INTEGRATIVE EXERCISE Putting Concepts Together

The K_{sp} at 298 K for iron(II) fluoride is 2.4×10^{-6} . (a) Write a half-reaction that gives the likely products of the two-electron reduction of $\text{FeF}_2(s)$ in water. (b) Use the K_{sp} value and the standard reduction potential of $\text{Fe}^{2+}(aq)$ to calculate the standard reduction potential for the half-reaction in part (a). (c) Rationalize the difference between the reduction potential in part (a) and the reduction potential for $\text{Fe}^{2+}(aq)$.

SOLUTION

Analyze We are going to have to combine what we know about equilibrium constants and electrochemistry to obtain reduction potentials.

Plan For (a) we need to determine which ion, Fe^{2+} or F^- , is more likely to be reduced by two electrons and complete the overall reaction $\text{FeF}_2 + 2 e^- \longrightarrow ?$. For (b) we need to write the chemical equation associated with the K_{sp} and see how it relates to E° for the reduction half-reaction in (a). For (c) we need to compare E° from (b) with the value for the reduction of Fe^{2+} .

Solve

(a) Iron(II) fluoride is an ionic substance that consists of Fe^{2+} and F^- ions. We are asked to predict where two electrons could be added to FeF_2 . We cannot envision adding the electrons to the F^- ions to form F^{2-} , so it seems likely that we could reduce the Fe^{2+} ions to $\text{Fe}(s)$. We therefore predict the half-reaction

(b) The K_{sp} for FeF_2 refers to the following equilibrium: (Section 17.4)

We were also asked to use the standard reduction potential of Fe^{2+} , whose half-reaction and standard reduction potentials are listed in Appendix E:

According to Hess's law, if we can add chemical equations to get a desired equation, then we can add their associated thermodynamic state functions, like ΔH or ΔG , to determine that thermodynamic quantity for the desired reaction. ∞ (Section 5.6) So we need to consider whether the three equations we are working with can be combined in a similar fashion. Notice that if we add the K_{sp} reaction to the standard reduction half-reaction for Fe^{2+} , we get the half-reaction we want:

Reaction 3 is still a half-reaction, so we do see the free electrons.

If we knew ΔG° for reactions 1 and 2, we could add them to get ΔG° for reaction 3. We can relate ΔG° to E° by $\Delta G^\circ = -nFE^\circ$ (Equation 20.12) and to K by $\Delta G^\circ = -RT \ln K$ (Equation 19.20, see also Figure 20.14). Furthermore, we know that K for reaction 1 is the K_{sp} of FeF_2 , and we know E° for reaction 2. Therefore we can calculate ΔG° for reactions 1 and 2:

Reaction 1:

$$\Delta G^\circ = -RT \ln K = -(8.314 \text{ J/K mol})(298 \text{ K}) \ln(2.4 \times 10^{-6}) = 3.21 \times 10^4 \text{ J/mol}$$

Reaction 2:

$$\Delta G^\circ = -nFE^\circ = -(2)(96,485 \text{ C/mol})(-0.440 \text{ J/C}) = 8.49 \times 10^4 \text{ J/mol}$$

(Recall that 1 volt is 1 joule per coulomb.)

Then ΔG° for reaction 3, the one we want, is the sum of the ΔG° values for reactions 1 and 2:

$$3.21 \times 10^4 \text{ J/mol} + 8.49 \times 10^4 \text{ J/mol} = 1.17 \times 10^5 \text{ J/mol}$$

We can convert this to E° from the relationship $\Delta G^\circ = -nFE^\circ$:

$$\begin{aligned} 1.17 \times 10^5 \text{ J/mol} &= -(2)(96,485 \text{ C/mol}) E^\circ \\ E^\circ &= \frac{1.17 \times 10^5 \text{ J/mol}}{-(2)(96,485 \text{ C/mol})} = -0.606 \text{ J/C} = -0.606 \text{ V} \end{aligned}$$

(c) The standard reduction potential for FeF_2 (-0.606 V) is more negative than that for Fe^{2+} (-0.440 V), telling us that the reduction of FeF_2 is the less favorable process. When FeF_2 is reduced, we not only reduce the Fe^{2+} ions but also break up the ionic solid. Because this additional energy must be overcome, the reduction of FeF_2 is less favorable than the reduction of Fe^{2+} .

CHAPTER SUMMARY AND KEY TERMS

INTRODUCTION AND SECTION 20.1 In this chapter we have focused on **electrochemistry**, the branch of chemistry that relates electricity and chemical reactions. Electrochemistry involves oxidation-reduction reactions, also called redox reactions. These reactions involve a change in the oxidation state of one or more elements. In every oxidation-reduction reaction one substance is oxidized (its oxidation state, or number, increases) and one substance is reduced (its oxidation state, or number, decreases). The substance that is oxidized is referred to as a **reducing agent**, or **reductant**, because it causes the reduction of some other substance. Similarly, the substance that is reduced is referred to as an **oxidizing agent**, or **oxidant**, because it causes the oxidation of some other substance.

SECTION 20.2 An oxidation-reduction reaction can be balanced by dividing the reaction into two **half-reactions**, one for oxidation and one for reduction. A half-reaction is a balanced chemical equation that includes electrons. In oxidation half-reactions the electrons are on the product (right) side of the equation; we can envision that these electrons are transferred from a substance when it is oxidized. In reduction half-reactions the electrons are on the reactant (left) side of the equation. Each half-reaction is balanced separately, and the two are brought together with proper coefficients to balance the electrons on each side of the equation, so the electrons cancel when the half-reactions are added.

SECTION 20.3 A **voltaic** (or **galvanic**) **cell** uses a spontaneous oxidation-reduction reaction to generate electricity. In a voltaic cell the oxidation and reduction half-reactions often occur in separate half-cells. Each half-cell has a solid surface called an electrode, where the half-reaction occurs. The electrode where oxidation occurs is called the **anode**; reduction occurs at the **cathode**. The electrons released at the anode flow through an external circuit (where they do electrical work) to the cathode. Electrical neutrality in the solution is maintained by the migration of ions between the two half-cells through a device such as a salt bridge.

SECTION 20.4 A voltaic cell generates an **electromotive force (emf)** that moves the electrons from the anode to the cathode through the external circuit. The origin of emf is a difference in the electrical potential energy of the two electrodes in the cell. The emf of a cell is called its **cell potential**, E_{cell} , and is measured in volts ($1 \text{ V} = 1 \text{ J/C}$). The cell potential under standard conditions is called the **standard emf**, or the **standard cell potential**, and is denoted E_{cell}° .

A **standard reduction potential**, E_{red}° , can be assigned for an individual half-reaction. This is achieved by comparing the potential of the half-reaction to that of the **standard hydrogen electrode (SHE)**, which is defined to have $E_{\text{red}}^{\circ} = 0 \text{ V}$ and is based on the following half-reaction:

The standard cell potential of a voltaic cell is the difference between the standard reduction potentials of the half-reactions that occur at the cathode and the anode: $E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode})$. The value of E_{cell}° is positive for a voltaic cell.

For a reduction half-reaction, E_{red}° is a measure of the tendency of the reduction to occur; the more positive the value for E_{red}° , the greater the tendency of the substance to be reduced. Thus, E_{red}° provides a measure of the oxidizing strength of a substance. Substances that are strong oxidizing agents produce products that are weak reducing agents, and vice versa.

SECTION 20.5 The emf, E , is related to the change in the Gibbs free energy, ΔG : $\Delta G = -nFE$, where n is the number of electrons

transferred during the redox process and F is **Faraday's constant**, defined as the quantity of electrical charge on one mole of electrons: $F = 96,485 \text{ C/mol}$. Because E is related to ΔG , the sign of E indicates whether a redox process is spontaneous: $E > 0$ indicates a spontaneous process, and $E < 0$ indicates a nonspontaneous one. Because ΔG is also related to the equilibrium constant for a reaction ($\Delta G = -RT \ln K$), we can relate E to K as well.

The maximum amount of electrical work produced by a voltaic cell is given by the product of the total charge delivered, nF , and the emf, E : $w_{\text{max}} = -nFE$. The watt is a unit of power: $1 \text{ W} = 1 \text{ J/s}$. Electrical work is often measured in kilowatt-hours.

SECTION 20.6 The emf of a redox reaction varies with temperature and with the concentrations of reactants and products. The **Nernst equation** relates the emf under nonstandard conditions to the standard emf and the reaction quotient Q :

$$E = E^{\circ} - (RT/nF) \ln Q = E^{\circ} - (0.0592/n) \log Q$$

The factor 0.0592 is valid when $T = 298 \text{ K}$. A **concentration cell** is a voltaic cell in which the same half-reaction occurs at both the anode and cathode but with different concentrations of reactants in each half-cell. At equilibrium, $Q = K$ and $E = 0$.

SECTION 20.7 A **battery** is a self-contained electrochemical power source that contains one or more voltaic cells. Batteries are based on a variety of different redox reactions. Several common batteries were discussed. The lead-acid battery, the nickel-cadmium battery, the nickel-metal-hydride battery, and the lithium-ion battery are examples of rechargeable batteries. The common alkaline dry cell is not rechargeable. **Fuel cells** are voltaic cells that utilize redox reactions in which reactants such as H_2 have to be continuously supplied to the cell to generate voltage.

SECTION 20.8 Electrochemical principles help us understand **corrosion**, undesirable redox reactions in which a metal is attacked by some substance in its environment. The corrosion of iron into rust is caused by the presence of water and oxygen, and it is accelerated by the presence of electrolytes, such as road salt. The protection of a metal by putting it in contact with another metal that more readily undergoes oxidation is called **cathodic protection**. Galvanized iron, for example, is coated with a thin layer of zinc; because zinc is oxidized more readily than iron, the zinc serves as a sacrificial anode in the redox reaction.

SECTION 20.9 An **electrolysis reaction**, which is carried out in an **electrolytic cell**, employs an external source of electricity to drive a nonspontaneous electrochemical reaction. The current-carrying medium within an electrolytic cell may be either a molten salt or an electrolyte solution. The products of electrolysis can generally be predicted by comparing the reduction potentials associated with possible oxidation and reduction processes. The electrodes in an electrolytic cell can be active, meaning that the electrode can be involved in the electrolysis reaction. Active electrodes are important in electroplating and in metallurgical processes.

The quantity of substances formed during electrolysis can be calculated by considering the number of electrons involved in the redox reaction and the amount of electrical charge that passes into the cell. The amount of electrical charge is measured in coulombs and is related to the magnitude of the current and the time it flows ($1 \text{ C} = 1 \text{ A}\cdot\text{s}$). Electrometallurgy is the use of electrolytic methods to prepare or purify a metallic element. Aluminum is obtained in the Hall-Héroult process by electrolysis of Al_2O_3 in molten cryolite (Na_3AlF_6).

KEY SKILLS

- Identify oxidation, reduction, oxidizing agent, and reducing agent in a chemical equation. (Section 20.1)
- Complete and balance redox equations using the method of half-reactions. (Section 20.2)
- Sketch a voltaic cell and identify its cathode, anode, and the directions that electrons and ions move. (Section 20.3)
- Calculate standard emfs (cell potentials), E_{cell}° , from standard reduction potentials. (Section 20.4)
- Use reduction potentials to predict whether a redox reaction is spontaneous. (Section 20.4)
- Relate E_{cell}° to ΔG° and equilibrium constants. (Section 20.5)
- Calculate emf under nonstandard conditions. (Section 20.6)
- Describe the components of common batteries and fuel cells. (Section 20.7)
- Explain how corrosion occurs and how it is prevented by cathodic protection. (Section 20.8)
- Describe the reactions in electrolytic cells. (Section 20.9)
- Relate amounts of products and reactants in redox reactions to electrical charge. (Section 20.9)

KEY EQUATIONS

- $E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode})$ [20.8] Relating standard emf to standard reduction potentials of the reduction (cathode) and oxidation (anode) half-reactions
- $\Delta G = -nFE$ [20.11] Relating free-energy change and emf
- $E = E^{\circ} - \frac{0.0592 \text{ V}}{n} \log Q$ (at 298 K) [20.18] The Nernst equation, expressing the effect of concentration on cell potential

EXERCISES

VISUALIZING CONCEPTS

- 20.1** In the Brønsted-Lowry concept of acids and bases, acid–base reactions are viewed as proton-transfer reactions. The stronger the acid, the weaker is its conjugate base. In what ways are redox reactions analogous? [Sections 20.1 and 20.2]
- 20.2** You may have heard that “antioxidants” are good for your health. Based on what you have learned in this chapter, what do you deduce an “antioxidant” is? [Sections 20.1 and 20.2]
- 20.3** The diagram that follows represents a molecular view of a process occurring at an electrode in a voltaic cell.

(a) Does the process represent oxidation or reduction? (b) Is the electrode the anode or cathode? (c) Why are the atoms in the electrode represented by larger spheres than the ions in the solution? [Section 20.3]

- 20.4** Assume that you want to construct a voltaic cell that uses the following half-reactions:

You begin with the incomplete cell pictured here in which the electrodes are immersed in water.

- (a) What additions must you make to the cell for it to generate a standard emf? (b) Which electrode functions as the cathode? (c) Which direction do electrons move through the external circuit? (d) What voltage will the cell generate under standard conditions? [Sections 20.3 and 20.4]
- 20.5** For a spontaneous reaction $\text{A}(\text{aq}) + \text{B}(\text{aq}) \longrightarrow \text{A}^{-}(\text{aq}) + \text{B}^{+}(\text{aq})$, answer the following questions:
- (a) If you made a voltaic cell out of this reaction, what half-reaction would be occurring at the cathode, and what half-reaction would be occurring at the anode?
- (b) Which half-reaction from (a) is higher in potential energy?
- (c) What is the sign of E_{cell}° ? [Section 20.3]

20.6 Consider the following table of standard electrode potentials for a series of hypothetical reactions in aqueous solution:

Reduction Half-Reaction	$E^\circ(\text{V})$
$\text{A}^+(\text{aq}) + \text{e}^- \longrightarrow \text{A}(\text{s})$	1.33
$\text{B}^{2+}(\text{aq}) + 2\text{e}^- \longrightarrow \text{B}(\text{s})$	0.87
$\text{C}^{3+}(\text{aq}) + \text{e}^- \longrightarrow \text{C}^{2+}(\text{aq})$	-0.12
$\text{D}^{3+}(\text{aq}) + 3\text{e}^- \longrightarrow \text{D}(\text{s})$	-1.59

- (a) Which substance is the strongest oxidizing agent? Which is weakest?
 (b) Which substance is the strongest reducing agent? Which is weakest?
 (c) Which substance(s) can oxidize C^{2+} ? [Sections 20.4 and 20.5]

20.7 Consider a redox reaction for which E° is a negative number.

- (a) What is the sign of ΔG° for the reaction?
 (b) Will the equilibrium constant for the reaction be larger or smaller than 1?
 (c) Can an electrochemical cell based on this reaction accomplish work on its surroundings? [Section 20.5]

20.8 Consider the following voltaic cell:

- (a) Which electrode is the cathode?
 (b) How would you determine the standard emf generated by this cell?
 (c) What is the change in the cell voltage when the ion concentrations in the cathode half-cell are increased by a factor of 10?
 (d) What is the change in the cell voltage when the ion concentrations in the anode half-cell are increased by a factor of 10? [Sections 20.4 and 20.6]

20.9 Consider the half-reaction $\text{Ag}^+(\text{aq}) + \text{e}^- \longrightarrow \text{Ag}(\text{s})$. (a) Which of the lines in the following diagram indicates how the reduction potential varies with the concentration of Ag^+ ? (b) What is the value of E_{red} when $\log[\text{Ag}^+] = 0$? [Section 20.6]

20.10 Draw a generic picture of a fuel cell. What is the main difference between it and a battery, regardless of the redox reactions that occur inside? [Section 20.7]

20.11 How does a zinc coating on iron protect the iron from unwanted oxidation? [Section 20.8]

20.12 Magnesium is produced commercially by electrolysis from a molten salt using a cell similar to the one shown here. (a) What salt is used as the electrolyte? (b) Which electrode is the anode, and which one is the cathode? (c) Write the overall cell reaction and individual half-reactions. (d) What precautions would need to be taken with respect to the magnesium formed? [Section 20.9]

OXIDATION-REDUCTION REACTIONS (section 20.1)

20.13 (a) What is meant by the term *oxidation*? (b) On which side of an oxidation half-reaction do the electrons appear? (c) What is meant by the term *oxidant*? (d) What is meant by the term *oxidizing agent*?

20.14 (a) What is meant by the term *reduction*? (b) On which side of a reduction half-reaction do the electrons appear? (c) What is meant by the term *reductant*? (d) What is meant by the term *reducing agent*?

20.15 Indicate whether each of the following statements is true or false:

- (a) If something is oxidized, it is formally losing electrons.

(b) For the reaction $\text{Fe}^{3+}(\text{aq}) + \text{Co}^{2+}(\text{aq}) \longrightarrow \text{Fe}^{2+}(\text{aq}) + \text{Co}^{3+}(\text{aq})$, $\text{Fe}^{3+}(\text{aq})$ is the reducing agent and $\text{Co}^{2+}(\text{aq})$ is the oxidizing agent.

(c) If there are no changes in the oxidation state of the reactants or products of a particular reaction, that reaction is not a redox reaction.

20.16 Indicate whether each of the following statements is true or false:

- (a) If something is reduced, it is formally losing electrons.
 (b) A reducing agent gets oxidized as it reacts.
 (c) Oxidizing agents can convert CO into CO_2 .

20.17 In each of the following balanced oxidation-reduction equations, identify those elements that undergo changes in oxidation number and indicate the magnitude of the change in each case.

20.18 Indicate whether the following balanced equations involve oxidation-reduction. If they do, identify the elements that undergo changes in oxidation number.

BALANCING OXIDATION-REDUCTION REACTIONS (section 20.2)

20.19 At 900 °C titanium tetrachloride vapor reacts with molten magnesium metal to form solid titanium metal and molten magnesium chloride. (a) Write a balanced equation for this reaction. (b) What is being oxidized, and what is being reduced? (c) Which substance is the reductant, and which is the oxidant?

20.20 Hydrazine (N_2H_4) and dinitrogen tetroxide (N_2O_4) form a self-igniting mixture that has been used as a rocket propellant. The reaction products are N_2 and H_2O . (a) Write a balanced chemical equation for this reaction. (b) What is being oxidized, and what is being reduced? (c) Which substance serves as the reducing agent and which as the oxidizing agent?

20.21 Complete and balance the following half-reactions. In each case indicate whether the half-reaction is an oxidation or a reduction.

20.22 Complete and balance the following half-reactions. In each case indicate whether the half-reaction is an oxidation or a reduction.

20.23 Complete and balance the following equations, and identify the oxidizing and reducing agents:

20.24 Complete and balance the following equations, and identify the oxidizing and reducing agents. (Recall that the O atoms in hydrogen peroxide, H_2O_2 , have an atypical oxidation state.)

VOLTAIC CELLS (section 20.3)

20.25 (a) What are the similarities and differences between Figure 20.3 and Figure 20.4? (b) Why are Na^+ ions drawn into the cathode half-cell as the voltaic cell shown in Figure 20.5 operates?

20.26 (a) What is the role of the porous glass disc shown in Figure 20.4? (b) Why do NO_3^- ions migrate into the anode half-cell as the voltaic cell shown in Figure 20.5 operates?

20.27 A voltaic cell similar to that shown in Figure 20.5 is constructed. One electrode half-cell consists of a silver strip placed in a

solution of AgNO_3 , and the other has an iron strip placed in a solution of FeCl_2 . The overall cell reaction is

(a) What is being oxidized, and what is being reduced? (b) Write the half-reactions that occur in the two half-cells. (c) Which electrode is the anode, and which is the cathode? (d) Indicate the signs of the electrodes. (e) Do electrons flow from the silver electrode to the iron electrode or from the iron to the silver? (f) In which directions do the cations and anions migrate through the solution?

- 20.28 A voltaic cell similar to that shown in Figure 20.5 is constructed. One half-cell consists of an aluminum strip placed in a solution of $\text{Al}(\text{NO}_3)_3$, and the other has a nickel strip placed in a solution of NiSO_4 . The overall cell reaction is

- (a) What is being oxidized, and what is being reduced?
 (b) Write the half-reactions that occur in the two half-cells.

(c) Which electrode is the anode, and which is the cathode? (d) Indicate the signs of the electrodes. (e) Do electrons flow from the aluminum electrode to the nickel electrode or from the nickel to the aluminum? (f) In which directions do the cations and anions migrate through the solution? Assume the Al is not coated with its oxide.

CELL POTENTIALS UNDER STANDARD CONDITIONS (section 20.4)

- 20.29 (a) What does the term *electromotive force* mean? (b) What is the definition of the *volt*? (c) What does the term *cell potential* mean?

- 20.30 (a) Which electrode of a voltaic cell, the cathode or the anode, corresponds to the higher potential energy for the electrons? (b) What are the units for electrical potential? How does this unit relate to energy expressed in joules? (c) What is special about a *standard* cell potential?

- 20.31 (a) Write the half-reaction that occurs at a hydrogen electrode in acidic aqueous solution when it serves as the cathode of a voltaic cell. (b) What is *standard* about the standard hydrogen electrode? (c) What is the role of the platinum foil in a standard hydrogen electrode?

- 20.32 (a) Write the half-reaction that occurs at a hydrogen electrode in acidic aqueous solution when it serves as the anode of a voltaic cell. (b) The platinum electrode in a standard hydrogen electrode is specially prepared to have a large surface area. Why is this important? (c) Sketch a standard hydrogen electrode.

- 20.33 (a) What is a *standard reduction potential*? (b) What is the standard reduction potential of a standard hydrogen electrode?

- 20.34 (a) Why is it impossible to measure the standard reduction potential of a single half-reaction? (b) Describe how the standard reduction potential of a half-reaction can be determined.

- 20.35 A voltaic cell that uses the reaction

has a measured standard cell potential of +1.19 V. (a) Write the two half-cell reactions. (b) By using data from Appendix E, determine E_{red}° for the reduction of $\text{Tl}^{3+}(aq)$ to $\text{Tl}^{+}(aq)$. (c) Sketch the voltaic cell, label the anode and cathode, and indicate the direction of electron flow.

- 20.36 A voltaic cell that uses the reaction

has a measured standard cell potential of +1.03 V. (a) Write the two half-cell reactions. (b) By using data from Appendix E, determine E_{red}° for the reaction involving Pd. (c) Sketch the voltaic cell, label the anode and cathode, and indicate the direction of electron flow.

- 20.37 Using standard reduction potentials (Appendix E), calculate the standard emf for each of the following reactions:

- (a) $\text{Cl}_2(g) + 2 \text{I}^{-}(aq) \longrightarrow 2 \text{Cl}^{-}(aq) + \text{I}_2(s)$
 (b) $\text{Ni}(s) + 2 \text{Ce}^{4+}(aq) \longrightarrow \text{Ni}^{2+}(aq) + 2 \text{Ce}^{3+}(aq)$
 (c) $\text{Fe}(s) + 2 \text{Fe}^{3+}(aq) \longrightarrow 3 \text{Fe}^{2+}(aq)$
 (d) $2 \text{NO}_3^{-}(aq) + 8 \text{H}^{+}(aq) + 3 \text{Cu}(s) \longrightarrow 2 \text{NO}(g) + 4 \text{H}_2\text{O}(l) + 3 \text{Cu}^{2+}(aq)$

- 20.38 Using data in Appendix E, calculate the standard emf for each of the following reactions:

- (a) $\text{H}_2(g) + \text{F}_2(g) \longrightarrow 2 \text{H}^{+}(aq) + 2 \text{F}^{-}(aq)$
 (b) $\text{Cu}^{2+}(aq) + \text{Ca}(s) \longrightarrow \text{Cu}(s) + \text{Ca}^{2+}(aq)$
 (c) $3 \text{Fe}^{2+}(aq) \longrightarrow \text{Fe}(s) + 2 \text{Fe}^{3+}(aq)$
 (d) $2 \text{ClO}_3^{-}(aq) + 10 \text{Br}^{-}(aq) + 12 \text{H}^{+}(aq) \longrightarrow \text{Cl}_2(g) + 5 \text{Br}_2(l) + 6 \text{H}_2\text{O}(l)$

- 20.39 The standard reduction potentials of the following half-reactions are given in Appendix E:

(a) Determine which combination of these half-cell reactions leads to the cell reaction with the largest positive cell potential and calculate the value. (b) Determine which combination of these half-cell reactions leads to the cell reaction with the smallest positive cell potential and calculate the value.

- 20.40 Given the following half-reactions and associated standard reduction potentials:

(a) Write the equation for the combination of these half-cell reactions that leads to the largest positive emf and calculate the value. (b) Write the equation for the combination of half-cell reactions that leads to the smallest positive emf and calculate that value.

- 20.41 A 1 M solution of $\text{Cu}(\text{NO}_3)_2$ is placed in a beaker with a strip of Cu metal. A 1 M solution of SnSO_4 is placed in a second beaker with a strip of Sn metal. A salt bridge connects the two beakers, and wires to a voltmeter link the two metal electrodes.

(a) Which electrode serves as the anode and which as the cathode? (b) Which electrode gains mass and which loses mass as the cell reaction proceeds? (c) Write the equation for the overall cell reaction. (d) What is the emf generated by the cell under standard conditions?

- 20.42 A voltaic cell consists of a strip of cadmium metal in a solution of $\text{Cd}(\text{NO}_3)_2$ in one beaker, and in the other beaker a platinum electrode is immersed in a NaCl solution, with Cl_2 gas bubbled around the electrode. A salt bridge connects the two beakers. (a) Which electrode serves as the anode and which as the cathode? (b) Does the Cd electrode gain or lose mass as the cell reaction proceeds? (c) Write the equation for the overall cell reaction. (d) What is the emf generated by the cell under standard conditions?

STRENGTHS OF OXIDIZING AND REDUCING AGENTS (section 20.4)

- 20.43** From each of the following pairs of substances, use data in Appendix E to choose the one that is the stronger reducing agent:
- Fe(s) or Mg(s)
 - Ca(s) or Al(s)
 - H₂(g, acidic solution) or H₂S(g)
 - BrO₃⁻(aq) or IO₃⁻(aq)
- 20.44** From each of the following pairs of substances, use data in Appendix E to choose the one that is the stronger oxidizing agent:
- Cl₂(g) or Br₂(l)
 - Zn²⁺(aq) or Cd²⁺(aq)
 - Cl⁻(aq) or ClO₃⁻(aq)
 - H₂O₂(aq) or O₃(g)
- 20.45** By using the data in Appendix E, determine whether each of the following substances is likely to serve as an oxidant or a reductant: (a) Cl₂(g), (b) MnO₄⁻(aq, acidic solution), (c) Ba(s), (d) Zn(s).
- 20.46** Is each of the following substances likely to serve as an oxidant or a reductant: (a) Ce³⁺(aq), (b) Ca(s), (c) ClO₃⁻(aq), (d) N₂O₅(g)?
- 20.47** (a) Assuming standard conditions, arrange the following in order of increasing strength as oxidizing agents in acidic solution: Cr₂O₇²⁻, H₂O₂, Cu²⁺, Cl₂, O₂. (b) Arrange the following in order of increasing strength as reducing agents in acidic solution: Zn, I⁻, Sn²⁺, H₂O₂, Al.
- 20.48** Based on the data in Appendix E, (a) which of the following is the strongest oxidizing agent and which is the weakest in acidic solution: Br₂, H₂O₂, Zn, Cr₂O₇²⁻? (b) Which of the following is the strongest reducing agent, and which is the weakest in acidic solution: F⁻, Zn, N₂H₅⁺, I₂, NO?
- 20.49** The standard reduction potential for the reduction of Eu³⁺(aq) to Eu²⁺(aq) is -0.43 V. Using Appendix E, which of the following substances is capable of reducing Eu³⁺(aq) to Eu²⁺(aq) under standard conditions: Al, Co, H₂O₂, N₂H₅⁺, H₂C₂O₄?
- 20.50** The standard reduction potential for the reduction of RuO₄⁻(aq) to RuO₄²⁻(aq) is +0.59 V. By using Appendix E, which of the following substances can oxidize RuO₄²⁻(aq) to RuO₄⁻(aq) under standard conditions: Br₂(l), BrO₃⁻(aq), Mn²⁺(aq), O₂(g), Sn²⁺(aq)?

FREE ENERGY AND REDOX REACTIONS (section 20.5)

- 20.51** Given the following reduction half-reactions:

(a) Write balanced chemical equations for the oxidation of Fe²⁺(aq) by S₂O₆²⁻(aq), by N₂O(aq), and by VO₂⁺(aq). (b) Calculate ΔG° for each reaction at 298 K. (c) Calculate the equilibrium constant K for each reaction at 298 K.

- 20.52** For each of the following reactions, write a balanced equation, calculate the standard emf, calculate ΔG° at 298 K, and calculate the equilibrium constant K at 298 K. (a) Aqueous iodide ion is oxidized to I₂(s) by Hg₂²⁺(aq). (b) In acidic solution, copper(I) ion is oxidized to copper(II) ion by nitrate ion. (c) In basic solution, Cr(OH)₃(s) is oxidized to CrO₄²⁻(aq) by ClO⁻(aq).

20.53 If the equilibrium constant for a two-electron redox reaction at 298 K is 1.5 × 10⁻⁴, calculate the corresponding ΔG° and E_{red}^o.

20.54 If the equilibrium constant for a one-electron redox reaction at 298 K is 8.7 × 10⁴, calculate the corresponding ΔG° and E_{red}^o.

20.55 Using the standard reduction potentials listed in Appendix E, calculate the equilibrium constant for each of the following reactions at 298 K:

20.56 Using the standard reduction potentials listed in Appendix E, calculate the equilibrium constant for each of the following reactions at 298 K:

20.57 A cell has a standard cell potential of +0.177 V at 298 K. What is the value of the equilibrium constant for the reaction (a) if n = 1? (b) if n = 2? (c) if n = 3?

20.58 At 298 K a cell reaction has a standard cell potential of +0.17 V. The equilibrium constant for the reaction is 5.5 × 10⁵. What is the value of n for the reaction?

20.59 A voltaic cell is based on the reaction

Under standard conditions, what is the maximum electrical work, in joules, that the cell can accomplish if 75.0 g of Sn is consumed?

20.60 Consider the voltaic cell illustrated in Figure 20.5, which is based on the cell reaction

Under standard conditions, what is the maximum electrical work, in joules, that the cell can accomplish if 50.0 g of copper is formed?

CELL EMF UNDER NONSTANDARD CONDITIONS (section 20.6)

20.61 (a) Under what circumstances is the Nernst equation applicable? (b) What is the numerical value of the reaction quotient, Q , under standard conditions? (c) What happens to the emf of a cell if the concentrations of the reactants are increased?

20.62 (a) A voltaic cell is constructed with all reactants and products in their standard states. Will this condition hold as the cell operates? Explain. (b) Can the Nernst equation be used at temperatures other than room temperature? Explain. (c) What happens to the emf of a cell if the concentrations of the products are increased?

20.63 What is the effect on the emf of the cell shown in Figure 20.9, which has the overall reaction $\text{Zn}(s) + 2\text{H}^+(aq) \longrightarrow \text{Zn}^{2+}(aq) + \text{H}_2(g)$, for each of the following changes? (a) The pressure of the H_2 gas is increased in the cathode half-cell. (b) Zinc nitrate is added to the anode half-cell. (c) Sodium hydroxide is added to the cathode half-cell, decreasing $[\text{H}^+]$. (d) The surface area of the anode is doubled.

20.64 A voltaic cell utilizes the following reaction:

What is the effect on the cell emf of each of the following changes? (a) Water is added to the anode half-cell, diluting the solution. (b) The size of the aluminum electrode is increased. (c) A solution of AgNO_3 is added to the cathode half-cell, increasing the quantity of Ag^+ but not changing its concentration. (d) HCl is added to the AgNO_3 solution, precipitating some of the Ag^+ as AgCl .

20.65 A voltaic cell is constructed that uses the following reaction and operates at 298 K:

(a) What is the emf of this cell under standard conditions? (b) What is the emf of this cell when $[\text{Ni}^{2+}] = 3.00\text{ M}$ and $[\text{Zn}^{2+}] = 0.100\text{ M}$? (c) What is the emf of the cell when $[\text{Ni}^{2+}] = 0.200\text{ M}$ and $[\text{Zn}^{2+}] = 0.900\text{ M}$?

20.66 A voltaic cell utilizes the following reaction and operates at 298 K:

(a) What is the emf of this cell under standard conditions? (b) What is the emf of this cell when $[\text{Ce}^{4+}] = 3.0\text{ M}$, $[\text{Ce}^{3+}] = 0.10\text{ M}$, and $[\text{Cr}^{3+}] = 0.010\text{ M}$? (c) What is the emf of the cell when $[\text{Ce}^{4+}] = 0.010\text{ M}$, $[\text{Ce}^{3+}] = 2.0\text{ M}$, and $[\text{Cr}^{3+}] = 1.5\text{ M}$?

20.67 A voltaic cell utilizes the following reaction:

(a) What is the emf of this cell under standard conditions? (b) What is the emf of this cell when $[\text{Fe}^{2+}] = 1.3\text{ M}$, $[\text{Fe}^{3+}] = 0.010\text{ M}$, $P_{\text{O}_2} = 0.50\text{ atm}$, and the pH of the solution in the cathode half-cell is 3.50?

20.68 A voltaic cell utilizes the following reaction:

(a) What is the emf of this cell under standard conditions? (b) What is the emf for this cell when $[\text{Fe}^{3+}] = 3.50\text{ M}$, $P_{\text{H}_2} = 0.95\text{ atm}$, $[\text{Fe}^{2+}] = 0.0010\text{ M}$, and the pH in both half-cells is 4.00?

20.69 A voltaic cell is constructed with two Zn^{2+} -Zn electrodes. The two half-cells have $[\text{Zn}^{2+}] = 1.8\text{ M}$ and $[\text{Zn}^{2+}] = 1.00 \times 10^{-2}\text{ M}$, respectively. (a) Which electrode is the anode of the cell? (b) What is the standard emf of the cell? (c) What is the cell emf for the concentrations given? (d) For each electrode, predict whether $[\text{Zn}^{2+}]$ will increase, decrease, or stay the same as the cell operates.

20.70 A voltaic cell is constructed with two silver-silver chloride electrodes, each of which is based on the following half-reaction:

The two half-cells have $[\text{Cl}^-] = 0.0150\text{ M}$ and $[\text{Cl}^-] = 2.55\text{ M}$, respectively. (a) Which electrode is the cathode of the cell? (b) What is the standard emf of the cell? (c) What is the cell emf for the concentrations given? (d) For each electrode, predict whether $[\text{Cl}^-]$ will increase, decrease, or stay the same as the cell operates.

20.71 The cell in Figure 20.9 could be used to provide a measure of the pH in the cathode half-cell. Calculate the pH of the cathode half-cell solution if the cell emf at 298 K is measured to be $+0.684\text{ V}$ when $[\text{Zn}^{2+}] = 0.30\text{ M}$ and $P_{\text{H}_2} = 0.90\text{ atm}$.

20.72 A voltaic cell is constructed that is based on the following reaction:

(a) If the concentration of Sn^{2+} in the cathode half-cell is 1.00 M and the cell generates an emf of $+0.22\text{ V}$, what is the concentration of Pb^{2+} in the anode half-cell? (b) If the anode half-cell contains $[\text{SO}_4^{2-}] = 1.00\text{ M}$ in equilibrium with $\text{PbSO}_4(s)$, what is the K_{sp} of PbSO_4 ?

BATTERIES AND FUEL CELLS (section 20.7)

20.73 (a) What happens to the emf of a battery as it is used? Why does this happen? (b) The AA-size and D-size alkaline batteries are both 1.5-V batteries that are based on the same electrode reactions. What is the major difference between the two batteries? What performance feature is most affected by this difference?

20.74 (a) Suggest an explanation for why liquid water is needed in an alkaline battery. (b) What is the advantage of using highly concentrated or solid reactants in a voltaic cell?

20.75 During a period of discharge of a lead-acid battery, 402 g of Pb from the anode is converted into $\text{PbSO}_4(s)$. (a) What mass of

$\text{PbO}_2(s)$ is reduced at the cathode during this same period? (b) How many coulombs of electrical charge are transferred from Pb to PbO_2 ?

20.76 During the discharge of an alkaline battery, 4.50 g of Zn is consumed at the anode of the battery. (a) What mass of MnO_2 is reduced at the cathode during this discharge? (b) How many coulombs of electrical charge are transferred from Zn to MnO_2 ?

20.77 Heart pacemakers are often powered by lithium-silver chromate "button" batteries. The overall cell reaction is

- (a) Lithium metal is the reactant at one of the electrodes of the battery. Is it the anode or the cathode? (b) Choose the two half-reactions from Appendix E that *most closely approximate* the reactions that occur in the battery. What standard emf would be generated by a voltaic cell based on these half-reactions? (c) The battery generates an emf of +3.5 V. How close is this value to the one calculated in part (b)? (d) Calculate the emf that would be generated at body temperature, 37 °C. How does this compare to the emf you calculated in part (b)?
- 20.78 Mercuric oxide dry-cell batteries are often used where a high-energy density is required, such as in watches and cameras. The two half-cell reactions that occur in the battery are
- $$\text{HgO}(s) + \text{H}_2\text{O}(l) + 2 e^- \longrightarrow \text{Hg}(l) + 2 \text{OH}^-(aq)$$
- $$\text{Zn}(s) + 2 \text{OH}^-(aq) \longrightarrow \text{ZnO}(s) + \text{H}_2\text{O}(l) + 2 e^-$$
- (a) Write the overall cell reaction. (b) The value of E_{red}° for the cathode reaction is +0.098 V. The overall cell potential is +1.35 V. Assuming that both half-cells operate under standard conditions, what is the standard reduction potential for the anode reaction? (c) Why is the potential of the anode reac-

tion different than would be expected if the reaction occurred in an acidic medium?

- 20.79 (a) Suppose that an alkaline battery was manufactured using cadmium metal rather than zinc. What effect would this have on the cell emf? (b) What environmental advantage is provided by the use of nickel-metal-hydride batteries over nickel-cadmium batteries?
- 20.80 (a) The nonrechargeable lithium batteries used for photography use lithium metal as the anode. What advantages might be realized by using lithium rather than zinc, cadmium, lead, or nickel? (b) The rechargeable lithium-ion battery does not use lithium metal as an electrode material. Nevertheless, it still has a substantial advantage over nickel-based batteries. Suggest an explanation.
- 20.81 The hydrogen-oxygen fuel cell has a standard emf of 1.23 V. What advantages and disadvantages there to using this device as a source of power compared to a 1.55-V alkaline battery?
- 20.82 (a) What is the difference between a battery and a fuel cell? (b) Can the “fuel” of a fuel cell be a solid? Explain.

CORROSION (section 20.8)

- 20.83 (a) Write the anode and cathode reactions that cause the corrosion of iron metal to aqueous iron(II). (b) Write the balanced half-reactions involved in the air oxidation of $\text{Fe}^{2+}(aq)$ to $\text{Fe}_2\text{O}_3 \cdot 3 \text{H}_2\text{O}$.
- 20.84 (a) Based on standard reduction potentials, would you expect copper metal to oxidize under standard conditions in the presence of oxygen and hydrogen ions? (b) When the Statue of Liberty was refurbished, Teflon spacers were placed between the iron skeleton and the copper metal on the surface of the statue. What role do these spacers play?
- 20.85 (a) Magnesium metal is used as a sacrificial anode to protect underground pipes from corrosion. Why is the magnesium referred to as a “sacrificial anode”? (b) Looking in Appendix E, suggest what metal the underground pipes could be made from in order for magnesium to be successful as a sacrificial anode.

- 20.86 An iron object is plated with a coating of cobalt to protect against corrosion. Does the cobalt protect iron by cathodic protection? Explain.
- 20.87 A plumber’s handbook states that you should not connect a brass pipe directly to a galvanized steel pipe because electrochemical reactions between the two metals will cause corrosion. The handbook recommends you use instead an insulating fitting to connect them. Brass is a mixture of copper and zinc. What spontaneous redox reaction(s) might cause the corrosion? Justify your answer with standard emf calculations.
- 20.88 A plumber’s handbook states that you should not connect a copper pipe directly to a steel pipe because electrochemical reactions between the two metals will cause corrosion. The handbook recommends you use instead an insulating fitting to connect them. What spontaneous redox reaction(s) might cause the corrosion? Justify your answer with standard emf calculations.

ELECTROLYSIS (section 20.9)

- 20.89 (a) What is *electrolysis*? (b) Are electrolysis reactions thermodynamically spontaneous? Explain. (c) What process occurs at the anode in the electrolysis of molten NaCl? (d) Why is sodium metal not obtained when an aqueous solution of NaCl undergoes electrolysis?
- 20.90 (a) What is an *electrolytic cell*? (b) The negative terminal of a voltage source is connected to an electrode of an electrolytic cell. Is the electrode the anode or the cathode of the cell? Explain. (c) The electrolysis of water is often done with a small amount of sulfuric acid added to the water. What is the role of the sulfuric acid? (d) Why are active metals such as Al obtained by electrolysis using molten salts rather than aqueous solutions?
- 20.91 (a) A $\text{Cr}^{3+}(aq)$ solution is electrolyzed, using a current of 7.60 A. What mass of Cr(s) is plated out after 2.00 days? (b) What amperage is required to plate out 0.250 mol Cr from a Cr^{3+} solution in a period of 8.00 h?
- 20.92 Metallic magnesium can be made by the electrolysis of molten MgCl_2 . (a) What mass of Mg is formed by passing a current of 4.55 A through molten MgCl_2 , for 4.50 days? (b) How many minutes are needed to plate out 25.00 g Mg from molten MgCl_2 using 3.50 A of current?

- 20.93 (a) Calculate the mass of Li formed by electrolysis of molten LiCl by a current of 7.5×10^4 A flowing for a period of 24 h. Assume the electrolytic cell is 85% efficient. (b) What is the minimum voltage required to drive the reaction?
- 20.94 Elemental calcium is produced by the electrolysis of molten CaCl_2 . (a) What mass of calcium can be produced by this process if a current of 7.5×10^3 A is applied for 48 h? Assume that the electrolytic cell is 68% efficient. (b) What is the minimum voltage needed to cause the electrolysis?
- 20.95 Metallic gold is collected from below the anode when crude copper metal is refined by electrolysis. Explain this behavior.
- 20.96 The crude copper that is subjected to electrorefining contains tellurium as an impurity. The standard reduction potential between tellurium and its lowest common oxidation state, Te^{4+} , is

Given this information, describe the probable fate of tellurium impurities during electrorefining. Do the impurities fall to the bottom of the refining bath, unchanged, as copper is oxidized, or do they go into solution? If they go into solution, do they plate out on the cathode?

ADDITIONAL EXERCISES

20.97 A *disproportionation* reaction is an oxidation-reduction reaction in which the same substance is oxidized and reduced. Complete and balance the following disproportionation reactions:

20.98 This oxidation-reduction reaction in acidic solution is spontaneous:

A solution containing KMnO_4 and H_2SO_4 is poured into one beaker, and a solution of FeSO_4 is poured into another. A salt bridge is used to join the beakers. A platinum foil is placed in each solution, and a wire that passes through a voltmeter connects the two solutions. (a) Sketch the cell, indicating the anode and the cathode, the direction of electron movement through the external circuit, and the direction of ion migrations through the solutions. (b) Sketch the process that occurs at the atomic level at the surface of the anode. (c) Calculate the emf of the cell under standard conditions. (d) Calculate the emf of the cell at 298 K when the concentrations are the following: $\text{pH} = 0.0$, $[\text{Fe}^{2+}] = 0.10 \text{ M}$, $[\text{MnO}_4^-] = 1.50 \text{ M}$, $[\text{Fe}^{3+}] = 2.5 \times 10^{-4} \text{ M}$, $[\text{Mn}^{2+}] = 0.001 \text{ M}$.

20.99 A common shorthand way to represent a voltaic cell is

A double vertical line represents a salt bridge or a porous barrier. A single vertical line represents a change in phase, such as from solid to solution. (a) Write the half-reactions and overall cell reaction represented by $\text{Fe}|\text{Fe}^{2+}||\text{Ag}^+|\text{Ag}$; sketch the cell. (b) Write the half-reactions and overall cell reaction represented by $\text{Zn}|\text{Zn}^{2+}||\text{H}^+|\text{H}_2$; sketch the cell. (c) Using the notation just described, represent a cell based on the following reaction:

Pt is used as an inert electrode in contact with the ClO_3^- and Cl^- . Sketch the cell.

20.100 Predict whether the following reactions will be spontaneous in acidic solution under standard conditions: (a) oxidation of Sn to Sn^{2+} by I_2 (to form I^-), (b) reduction of Ni^{2+} to Ni by I^- (to form I_2), (c) reduction of Ce^{4+} to Ce^{3+} by H_2O_2 , (d) reduction of Cu^{2+} to Cu by Sn^{2+} (to form Sn^{4+}).

[20.101] Gold exists in two common positive oxidation states, +1 and +3. The standard reduction potentials for these oxidation states are

(a) Can you use these data to explain why gold does not tarnish in the air? (b) Suggest several substances that should be strong enough oxidizing agents to oxidize gold metal. (c) Miners obtain gold by soaking gold-containing ores in an aqueous solution of sodium cyanide. A very soluble complex ion of gold forms in the aqueous solution because of the redox reaction

What is being oxidized and what is being reduced in this reaction? (d) Gold miners then react the basic aqueous product solution from part (c) with Zn dust to get gold metal. Write a balanced redox reaction for this process. What is being oxidized, and what is being reduced?

20.102 A voltaic cell is constructed from an $\text{Ni}^{2+}(aq)$ -Ni(s) half-cell and an $\text{Ag}^+(aq)$ -Ag(s) half-cell. The initial concentration of $\text{Ni}^{2+}(aq)$ in the Ni^{2+} -Ni half-cell is $[\text{Ni}^{2+}] = 0.0100 \text{ M}$. The initial cell voltage is +1.12 V. (a) By using data in Table 20.1, calculate the standard emf of this voltaic cell. (b) Will the concentration of $\text{Ni}^{2+}(aq)$ increase or decrease as the cell operates? (c) What is the initial concentration of $\text{Ag}^+(aq)$ in the Ag^+ -Ag half-cell?

[20.103] A voltaic cell is constructed that uses the following half-cell reactions:

The cell is operated at 298 K with $[\text{Cu}^+] = 0.25 \text{ M}$ and $[\text{I}^-] = 3.5 \text{ M}$. (a) Determine E for the cell at these concentrations. (b) Which electrode is the anode of the cell? (c) Is the answer to part (b) the same as it would be if the cell were operated under standard conditions? (d) If $[\text{Cu}^+]$ was equal to 0.15 M , at what concentration of I^- would the cell have zero potential?

20.104 Using data from Appendix E, calculate the equilibrium constant for the disproportionation of the copper(I) ion at room temperature: $2 \text{Cu}^+(aq) \longrightarrow \text{Cu}^{2+}(aq) + \text{Cu}(s)$.

20.105 (a) Write the reactions for the discharge and charge of a nickel-cadmium (nicad) rechargeable battery. (b) Given the following reduction potentials, calculate the standard emf of the cell:

(c) A typical nicad voltaic cell generates an emf of +1.30 V. Why is there a difference between this value and the one you calculated in part (b)? (d) Calculate the equilibrium constant for the overall nicad reaction based on this typical emf value.

20.106 The capacity of batteries such as the typical AA alkaline battery is expressed in units of milliamp-hours (mAh). An AA alkaline battery yields a nominal capacity of 2850 mAh. (a) What quantity of interest to the consumer is being expressed by the units of mAh? (b) The starting voltage of a fresh alkaline battery is 1.55 V. The voltage decreases during discharge and is 0.80 V when the battery has delivered its rated capacity. If we assume that the voltage declines linearly as current is withdrawn, estimate the total maximum electrical work the battery could perform during discharge.

20.107 If you were going to apply a small potential to a steel ship resting in the water as a means of inhibiting corrosion, would you apply a negative or a positive charge? Explain.

[20.108] (a) How many coulombs are required to plate a layer of chromium metal 0.25 mm thick on an auto bumper with a total area of 0.32 m^2 from a solution containing CrO_4^{2-} ? The density of chromium metal is 7.20 g/cm^3 . (b) What current flow is required for this electroplating if the bumper is to be plated in 10.0 s? (c) If the external source has an emf of +6.0 V and the electrolytic cell is 65% efficient, how much electrical power is expended to electroplate the bumper?

- 20.109** Magnesium is obtained by electrolysis of molten MgCl_2 . (a) Why is an aqueous solution of MgCl_2 not used in the electrolysis? (b) Several cells are connected in parallel by very large copper buses that convey current to the cells. Assuming that the cells are 96% efficient in producing the desired products in electrolysis, what mass of Mg is formed by passing a current of 97,000 A for a period of 24 hr?
- 20.110** Calculate the number of kilowatt-hours of electricity required to produce 1.0×10^3 kg (1 metric ton) of aluminum by electrolysis of Al^{3+} if the applied voltage is 4.50 V and the process is 45% efficient.
- 20.111** Some years ago a unique proposal was made to raise the *Titanic*. The plan involved placing pontoons within the ship using a

surface-controlled submarine-type vessel. The pontoons would contain cathodes and would be filled with hydrogen gas formed by the electrolysis of water. It has been estimated that it would require about 7×10^8 mol of H_2 to provide the buoyancy to lift the ship (*J. Chem. Educ.*, 1973, Vol. 50, 61). (a) How many coulombs of electrical charge would be required? (b) What is the minimum voltage required to generate H_2 and O_2 if the pressure on the gases at the depth of the wreckage (2 mi) is 300 atm? (c) What is the minimum electrical energy required to raise the *Titanic* by electrolysis? (d) What is the minimum cost of the electrical energy required to generate the necessary H_2 if the electricity costs 85 cents per kilowatt-hour to generate at the site?

INTEGRATIVE EXERCISES

- 20.112** The Haber process is the principal industrial route for converting nitrogen into ammonia:

- (a) What is being oxidized, and what is being reduced? (b) Using the thermodynamic data in Appendix C, calculate the equilibrium constant for the process at room temperature. (c) Calculate the standard emf of the Haber process at room temperature.
- [20.113]** In a galvanic cell the cathode is an Ag^+ (1.00 M)/ $\text{Ag}(\text{s})$ half-cell. The anode is a standard hydrogen electrode immersed in a buffer solution containing 0.10 M benzoic acid ($\text{C}_6\text{H}_5\text{COOH}$) and 0.050 M sodium benzoate ($\text{C}_6\text{H}_5\text{COO}^-\text{Na}^+$). The measured cell voltage is 1.030 V. What is the $\text{p}K_a$ of benzoic acid?
- 20.114** Consider the general oxidation of a species A in solution: $\text{A} \longrightarrow \text{A}^+ + \text{e}^-$. The term *oxidation potential* is sometimes used to describe the ease with which species A is oxidized—the easier a species is to oxidize, the greater its oxidation potential. (a) What is the relationship between the standard oxidation potential of A and the standard reduction potential of A^+ ? (b) Which of the metals listed in Table 4.5 has the highest standard oxidation potential? Which has the lowest? (c) For a series of substances, the trend in oxidation potential is often related to the trend in the first ionization energy. Explain why this relationship makes sense.
- 20.115** A voltaic cell is based on $\text{Ag}^+(\text{aq})/\text{Ag}(\text{s})$ and $\text{Fe}^{3+}(\text{aq})/\text{Fe}^{2+}(\text{aq})$ half-cells. (a) What is the standard emf of the cell? (b) Which reaction occurs at the cathode and which at the anode of the cell? (c) Use S° values in Appendix C and the relationship between cell potential and free-energy change to predict whether the standard cell potential increases or decreases when the temperature is raised above 25 °C.
- 20.116** Hydrogen gas has the potential as a clean fuel in reaction with oxygen. The relevant reaction is

Consider two possible ways of utilizing this reaction as an electrical energy source: (i) Hydrogen and oxygen gases are combusted and used to drive a generator, much as coal is currently used in the electric power industry; (ii) hydrogen and oxygen gases are used to generate electricity directly by using fuel cells that operate at 85 °C. (a) Use data in Appendix C to calcu-

late ΔH° and ΔS° for the reaction. We will assume that these values do not change appreciably with temperature. (b) Based on the values from part (a), what trend would you expect for the magnitude of ΔG for the reaction as the temperature increases? (c) What is the significance of the change in the magnitude of ΔG with temperature with respect to the utility of hydrogen as a fuel? (d) Based on the analysis here, would it be more efficient to use the combustion method or the fuel-cell method to generate electrical energy from hydrogen?

- 20.117** Cytochrome, a complicated molecule that we will represent as CyFe^{2+} , reacts with the air we breathe to supply energy required to synthesize adenosine triphosphate (ATP). The body uses ATP as an energy source to drive other reactions. (Section 19.7) At pH 7.0 the following reduction potentials pertain to this oxidation of CyFe^{2+} :

(a) What is ΔG for the oxidation of CyFe^{2+} by air? (b) If the synthesis of 1.00 mol of ATP from adenosine diphosphate (ADP) requires a ΔG of 37.7 kJ, how many moles of ATP are synthesized per mole of O_2 ?

- [20.118]** The standard potential for the reduction of $\text{AgSCN}(\text{s})$ is +0.0895 V.

Using this value and the electrode potential for $\text{Ag}^+(\text{aq})$, calculate the K_{sp} for AgSCN .

- [20.119]** The K_{sp} value for $\text{PbS}(\text{s})$ is 8.0×10^{-28} . By using this value together with an electrode potential from Appendix E, determine the value of the standard reduction potential for the reaction

- [20.120]** A student designs an ammeter (a device that measures electrical current) that is based on the electrolysis of water into hydrogen and oxygen gases. When electrical current of unknown magnitude is run through the device for 2.00 min, 12.3 mL of water-saturated $\text{H}_2(\text{g})$ is collected. The temperature of the system is 25.5 °C, and the atmospheric pressure is 768 torr. What is the magnitude of the current in amperes?

WHAT'S AHEAD

21.1 RADIOACTIVITY

In this chapter we learn how to describe nuclear reactions by equations analogous to chemical equations, in which the nuclear charges and masses of reactants and products are in balance. Radioactive nuclei most commonly decay by emission of *alpha*, *beta*, or *gamma* radiation.

21.2 PATTERNS OF NUCLEAR STABILITY

We recognize that nuclear stability is determined largely by the *neutron-to-proton ratio*. For stable nuclei, this ratio increases with increasing atomic number. All nuclei with 84 or more protons are radioactive. Heavy nuclei gain stability by a series of nuclear disintegrations leading to stable nuclei.

21.3 NUCLEAR TRANSMUTATIONS

We study *nuclear transmutations*, which are nuclear reactions induced by bombardment of a nucleus by a neutron or an accelerated charged particle.

21.4 RATES OF RADIOACTIVE DECAY

We learn that radioisotope decays are first-order kinetic processes with characteristic half-lives. Decay rates can be used to determine the age of ancient artifacts and geological formations.

21

**THE REMNANT OF THE SUPERNOVA
CASSIOPEIA A** as viewed from the
Chandra X-ray Observatory.

21.5 DETECTION OF RADIOACTIVITY

We see that the radiation emitted by a radioactive substance can be detected by dosimeters, Geiger counters, and scintillation counters.

21.6 ENERGY CHANGES IN NUCLEAR REACTIONS

We recognize that energy changes in nuclear reactions are related to mass changes via Einstein's equation, $E = mc^2$. The *nuclear binding energy* of a nucleus is the difference between the mass of the nucleus and the sum of the masses of its nucleons.

21.7 NUCLEAR POWER: FISSION

We learn that in *nuclear fission* a heavy nucleus splits to form two or more product nuclei. This type of nuclear reaction is the energy

source for nuclear power plants, and we look at the operating principles of these plants.

21.8 NUCLEAR POWER: FUSION

We learn that in *nuclear fusion* two light nuclei are fused together to form a more stable, heavier nucleus.

21.9 RADIATION IN THE ENVIRONMENT AND LIVING SYSTEMS

We discover that naturally occurring radioisotopes bathe our planet—and us—with low levels of radiation. The radiation emitted in nuclear reactions can damage living cells but also has diagnostic and therapeutic applications.

NUCLEAR CHEMISTRY

ULTIMATELY THE CHEMICAL ENERGY that fuels life on Earth comes from sunlight. Plants convert the radiant energy of the Sun into chemical energy through photosynthesis, producing oxygen and carbohydrates. Life on Earth could not exist without energy from the Sun, but where does the Sun get its energy? Stars,

including our sun, use **nuclear reactions** that involve changes in atomic nuclei to generate their energy. For example, the Sun produces energy by fusing hydrogen atoms to form helium, releasing vast amounts of energy in the process.

The fusion of hydrogen to form helium is the dominant nuclear reaction for most of a star's lifetime. Toward the end of its life, the hydrogen in the star's core is exhausted and the helium atoms fuse to form progressively heavier elements. A select few stars end their lives in dramatic supernova explosions such as the one shown in the chapter opening photograph. The nuclear reactions that occur when a star goes supernova are responsible for the existence of all naturally occurring elements heavier than nickel.

Nuclear chemistry is the study of nuclear reactions, with an emphasis on their uses in chemistry and their effects on biological systems. Nuclear chemistry affects our lives in many ways, particularly in energy and medical applications. In radiation therapy, for example, gamma rays from a radioactive substance such as cobalt-60 are directed to cancerous tumors to destroy them. Positron emission tomography (PET) is one example of a medical diagnostic tool that relies on decay of a radioactive element injected into the body.

► **FIGURE 21.1** Sources of electricity generation, worldwide and for select countries.

Radioactivity is also used to help determine the mechanisms of chemical reactions, to trace the movement of atoms in biological systems and the environment, and to date historical artifacts.

Nuclear reactions are also used to generate electricity. Roughly 15% of the electricity generated worldwide comes from nuclear power plants, though the percentage varies from one country to the next, as ▲ **FIGURE 21.1** shows.

The use of nuclear energy for power generation and the disposal of nuclear wastes from power plants are controversial social and political issues. It is imperative, therefore, that as a citizen with a stake in these matters, you have some understanding of nuclear reactions and the uses of radioactive substances.

21.1 RADIOACTIVITY

To understand nuclear reactions, we must review and develop some ideas introduced in Section 2.3. First, recall that two types of subatomic particles reside in the nucleus: *protons* and *neutrons*. We will refer to these particles as **nucleons**. Recall also that all atoms of a given element have the same number of protons; this number is the element's *atomic number*. The atoms of a given element can have different numbers of neutrons, however, so they can have different *mass numbers*; the mass number is the total number of nucleons in the nucleus. Atoms with the same atomic number but different mass numbers are known as *isotopes*.

The different isotopes of an element are distinguished by their mass numbers. For example, the three naturally occurring isotopes of uranium are uranium-234, uranium-235, and uranium-238, where the numerical suffixes represent the mass numbers. These isotopes are also written ${}^{234}_{92}\text{U}$, ${}^{235}_{92}\text{U}$, and ${}^{238}_{92}\text{U}$, where the superscript is the mass number and the subscript is the atomic number.

Different isotopes of an element have different natural abundances. For example, 99.3% of naturally occurring uranium is uranium-238, 0.7% is uranium-235, and only a trace is uranium-234. Different isotopes of an element also have different stabilities. Indeed, the nuclear properties of any given isotope depend on the number of protons and neutrons in its nucleus.

A *nuclide* is a nucleus containing a specified number of protons and neutrons. Nuclides that are radioactive are called **radionuclides**, and atoms containing these nuclei are called **radioisotopes**.

Nuclear Equations

Most nuclei in nature are stable and remain intact indefinitely. Radionuclides, however, are unstable and spontaneously emit particles and electromagnetic radiation. Emission of radiation is one of the ways in which an unstable nucleus is transformed into a more stable one that has less energy. The emitted radiation is the carrier of the excess energy. Uranium-238, for example, is radioactive, undergoing a nuclear reaction emitting helium-4 nuclei. The helium-4 particles are known as **alpha (α) particles**, and a stream of them is called *alpha radiation*. When a ${}^{238}_{92}\text{U}$ nucleus loses an alpha particle, the remaining fragment has an atomic number of 90 and a mass number of 234. The element with atomic number 90 is Th, thorium. Therefore, the products of uranium-238 decomposition are an alpha particle and a thorium-234 nucleus. We represent this reaction by the *nuclear equation*

When a nucleus spontaneously decomposes in this way, it is said either to have decayed or to have undergone *radioactive decay*. Because an alpha particle is involved in this reaction, scientists also describe the process as **alpha decay**.

GIVE IT SOME THOUGHT

What change in the mass number of a nucleus occurs when the nucleus emits an alpha particle?

In Equation 21.1 the sum of the mass numbers is the same on both sides of the equation ($238 = 234 + 4$). Likewise, the sum of the atomic numbers on both sides of the equation is equal ($92 = 90 + 2$). Mass numbers and atomic numbers must be balanced in all nuclear equations.

The radioactive properties of the nucleus in an atom are independent of the chemical state of the atom. In writing nuclear equations, therefore, we are not concerned with the chemical form (element or compound) of the atom in which the nucleus resides.

SAMPLE EXERCISE 21.1 Predicting the Product of a Nuclear Reaction

What product is formed when radium-226 undergoes alpha decay?

SOLUTION

Analyze We are asked to determine the nucleus that results when radium-226 loses an alpha particle.

Plan We can best do this by writing a balanced nuclear reaction for the process.

Solve The periodic table shows that radium has an atomic number of 88. The complete chemical symbol for radium-226 is therefore ${}^{226}_{88}\text{Ra}$. An alpha particle is a helium-4 nucleus, and so its symbol is ${}^4_2\text{He}$ (sometimes written as ${}^4_2\alpha$). The alpha particle is a product of the nuclear reaction, and so the equation is of the form

where A is the mass number of the product nucleus and Z is its atomic number. Mass numbers and atomic numbers must balance, so

$$226 = A + 4$$

and

$$88 = Z + 2$$

Hence,

$$A = 222 \quad \text{and} \quad Z = 86$$

Again, from the periodic table, the element with $Z = 86$ is radon (Rn). The product, therefore, is ${}^{222}_{86}\text{Rn}$, and the nuclear equation is

PRACTICE EXERCISE

Which element undergoes alpha decay to form lead-208?

Answer: ${}^{212}_{84}\text{Po}$

TABLE 21.1 • Properties of Alpha, Beta, and Gamma Radiation

Property	Type of Radiation		
	α	β	γ
Charge	2+	1−	0
Mass	6.64×10^{-24} g	9.11×10^{-28} g	0
Relative penetrating power	1	100	10,000
Nature of radiation	${}^4_2\text{He}$ nuclei	Electrons	High-energy photons

Types of Radioactive Decay

The three most common kinds of radiation given off when a radionuclide decays are alpha (α), beta (β), and gamma (γ) radiation. ∞ (Section 2.2) \blacktriangle TABLE 21.1 summarizes some of the important properties of these types of radiation. As just described, alpha radiation consists of a stream of helium-4 nuclei known as alpha particles, which we denote as ${}^4_2\text{He}$ or α .

Beta radiation consists of streams of **beta (β) particles**, which are high-speed electrons emitted by an unstable nucleus. Beta particles are represented in nuclear equations by ${}_{-1}^0\text{e}$ or sometimes by ${}_{-1}^0\beta$. The superscript 0 indicates that the mass of the electron is exceedingly small relative to the mass of a nucleon. The subscript -1 represents the negative charge of the beta particle, which is opposite that of the proton.

Iodine-131 is an isotope that undergoes decay by **beta emission**:

You can see from this equation that beta decay causes the atomic number of the reactant to increase from 53 to 54, which means a proton was created. Therefore, beta emission is equivalent to the conversion of a neutron (${}^1_0\text{n}$) to a proton (${}^1_1\text{p}$ or ${}^1_1\text{H}$):

Just because an electron is emitted from a nucleus in beta decay, we should not think that the nucleus is composed of these particles any more than we consider a match to be composed of sparks simply because it gives them off when struck. The beta-particle electron comes into being only when the nucleus undergoes a nuclear reaction. Furthermore, the speed of the beta particle is sufficiently high that it does not end up in an orbital of the decaying atom.

Gamma (γ) radiation (or gamma rays) consists of high-energy photons (that is, electromagnetic radiation of very short wavelength). It changes neither the atomic number nor the mass number of a nucleus and is represented as either ${}^0_0\gamma$ or merely γ . Gamma radiation usually accompanies other radioactive emission because it represents the energy lost when the nucleons in a nuclear reaction reorganize into more stable arrangements. Generally, gamma rays are not shown when writing nuclear equations.

Two other types of radioactive decay are positron emission and electron capture. A **positron**, ${}^0_1\text{e}$, is a particle that has the same mass as an electron (thus, we use the letter e and superscript 0 for the mass) but the opposite charge (represented by the +1 subscript).*

The isotope carbon-11 decays by **positron emission**:

Positron emission causes the atomic number of the reactant in this equation to decrease from 6 to 5. In general, positron emission has the effect of converting a proton to a neutron, thereby decreasing the atomic number of the nucleus by 1:

*The positron has a very short life because it is annihilated when it collides with an electron, producing gamma rays: ${}^0_1\text{e} + {}_{-1}^0\text{e} \longrightarrow 2\gamma$.

Electron capture is the capture by the nucleus of an electron from the electron cloud surrounding the nucleus, as in this rubidium-81 decay:

Because the electron is consumed rather than formed in the process, it is shown on the reactant side of the equation. Electron capture, like positron emission, has the effect of converting a proton to a neutron:

► **TABLE 21.2** summarizes the symbols used to represent the particles commonly encountered in nuclear reactions. The various types of radioactive decay are summarized in ▼ **TABLE 21.3**.

TABLE 21.2 • Particles Found in Nuclear Reactions

Particle	Symbol
Neutron	${}_0^1\text{n}$
Proton	${}_1^1\text{H}$ or ${}_1^1\text{p}$
Electron	${}_{-1}^0\text{e}$
Alpha particle	${}_2^4\text{He}$ or ${}_2^4\alpha$
Beta particle	${}_{-1}^0\text{e}$ or ${}_{-1}^0\beta$
Positron	${}_{+1}^0\text{e}$

TABLE 21.3 • Types of Radioactive Decay

Type	Nuclear Equation	Change in Atomic Number	Change in Mass Number
Alpha decay	${}_Z^AX \longrightarrow {}_{Z-2}^{A-4}Y + {}_2^4\text{He}$	-2	-4
Beta emission	${}_Z^AX \longrightarrow {}_{Z+1}^AY + {}_{-1}^0\text{e}$	+1	Unchanged
Positron emission	${}_Z^AX \longrightarrow {}_{Z-1}^AY + {}_{+1}^0\text{e}$	-1	Unchanged
Electron capture*	${}_Z^AX + {}_{-1}^0\text{e} \longrightarrow {}_{Z-1}^AY$	-1	Unchanged

*The electron captured comes from the electron cloud surrounding the nucleus.

GIVE IT SOME THOUGHT

Which particles in Table 21.2 result in no change in nuclear charge when emitted in nuclear decay?

SAMPLE EXERCISE 21.2 Writing Nuclear Equations

Write nuclear equations for (a) mercury-201 undergoing electron capture; (b) thorium-231 decaying to protactinium-231.

SOLUTION

Analyze We must write balanced nuclear equations in which the masses and charges of reactants and products are equal.

Plan We can begin by writing the complete chemical symbols for the nuclei and decay particles that are given in the problem.

Solve

(a) The information given in the question can be summarized as

The mass numbers must have the same sum on both sides of the equation:

$$201 + 0 = A$$

Thus, the product nucleus must have a mass number of 201. Similarly, balancing the atomic numbers gives

$$80 - 1 = Z$$

Thus, the atomic number of the product nucleus must be 79, which identifies it as gold (Au):

(b) In this case we must determine what type of particle is emitted in the course of the radioactive decay:

From $231 = 231 + A$ and $90 = 91 + Z$, we deduce $A = 0$ and $Z = -1$. According to Table 21.2, the particle with these characteristics is the beta particle (electron). We therefore write

PRACTICE EXERCISE

Write a balanced nuclear equation for the reaction in which oxygen-15 undergoes positron emission.

21.2 | PATTERNS OF NUCLEAR STABILITY

No single rule allows us to predict whether a particular nucleus is radioactive and, if it is, how it might decay. However, several empirical observations can help us predict the stability of a nucleus.

Neutron-to-Proton Ratio

Because like charges repel each other, it may seem surprising that a large number of protons can reside within the small volume of the nucleus. At close distances, however, a strong force of attraction, called the *nuclear force*, exists between nucleons. Neutrons are intimately involved in this attractive force. All nuclei other than ${}^1_1\text{H}$ contain neutrons. As the number of protons in a nucleus increases, there is an ever greater need for neutrons to counteract the proton–proton repulsions. Stable nuclei with atomic numbers up to about 20 have approximately equal numbers of neutrons and protons. For nuclei with atomic number above 20, the number of neutrons exceeds the number of protons. Indeed, the number of neutrons necessary to create a stable nucleus increases more rapidly than the number of protons. Thus, the neutron-to-proton ratios of stable nuclei increase with increasing atomic number, as illustrated by the most common isotopes of carbon, ${}^{12}_6\text{C}$ ($n/p = 1$), manganese, ${}^{55}_{25}\text{Mn}$ ($n/p = 1.20$), and gold, ${}^{197}_{79}\text{Au}$ ($n/p = 1.49$).

The dark blue dots in ► **FIGURE 21.2** represent stable (nonradioactive) isotopes. The region of the graph covered by these dark blue dots is known as the *belt of stability*. The belt of stability ends at element 83 (bismuth), which means that *all nuclei with 84 or more protons are radioactive*. For example, all isotopes of uranium, $Z = 92$, are radioactive.

The type of radioactive decay that a particular radionuclide undergoes depends largely on how its neutron-to-proton ratio compares with those of nearby nuclei that lie within the belt of stability. We can envision three general situations:

- 1. Nuclei above the belt of stability (high neutron-to-proton ratios).** These neutron-rich nuclei can lower their ratio and thereby move toward the belt of stability by emitting a beta particle because beta emission decreases the number of neutrons and increases the number of protons (Equation 21.3).
- 2. Nuclei below the belt of stability (low neutron-to-proton ratios).** These proton-rich nuclei can increase their ratio and so move closer to the belt of stability by either positron emission or electron capture because both decays increase the number of neutrons and decrease the number of protons (Equations 21.5 and 21.7). Positron emission is more common among lighter nuclei. Electron capture becomes increasingly common as the nuclear charge increases.
- 3. Nuclei with atomic numbers ≥ 84 .** These heavy nuclei tend to undergo alpha emission, which decreases both the number of neutrons and the number of protons by two, moving the nucleus diagonally toward the belt of stability.

SAMPLE EXERCISE 21.3 Predicting Modes of Nuclear Decay

Predict the mode of decay of (a) carbon-14, (b) xenon-118.

SOLUTION

Analyze We are asked to predict the modes of decay of two nuclei.

Plan To do this, we must locate the respective nuclei in Figure 21.2 and determine their positions with respect to the belt of stability in order to predict the most likely mode of decay.

Solve

(a) Carbon is element 6. Thus, carbon-14 has 6 protons and $14 - 6 = 8$ neutrons, giving it a neutron-to-proton ratio of 1.25. Elements with $Z < 20$ normally have stable nuclei that contain approximately equal numbers of neutrons and protons ($n/p = 1$). Thus, carbon-14 is located above the belt of stability and we expect it to decay by emitting a beta particle to lessen the n/p ratio:

This is indeed the mode of decay observed for carbon-14, a reaction that lowers the n/p ratio from 1.25 to 1.0.

(b) Xenon is element 54. Thus, xenon-118 has 54 protons and $118 - 54 = 64$ neutrons, giving it an n/p ratio of 1.18. According to Figure 21.2, stable nuclei in this region of the belt of stability have higher neutron-to-proton ratios than xenon-118. The nucleus can increase this ratio by either positron emission or electron capture:

In this case both modes of decay are observed.

Comment Keep in mind that our guidelines do not always work. For example, thorium-233, which we might expect to undergo alpha decay, actually undergoes beta emission. Furthermore, a few radioactive nuclei lie within the belt of stability. Both ${}^{146}_{60}\text{Nd}$ and ${}^{148}_{60}\text{Nd}$, for example, are stable and lie in the belt of stability. ${}^{147}_{60}\text{Nd}$, however, which lies between them, is radioactive.

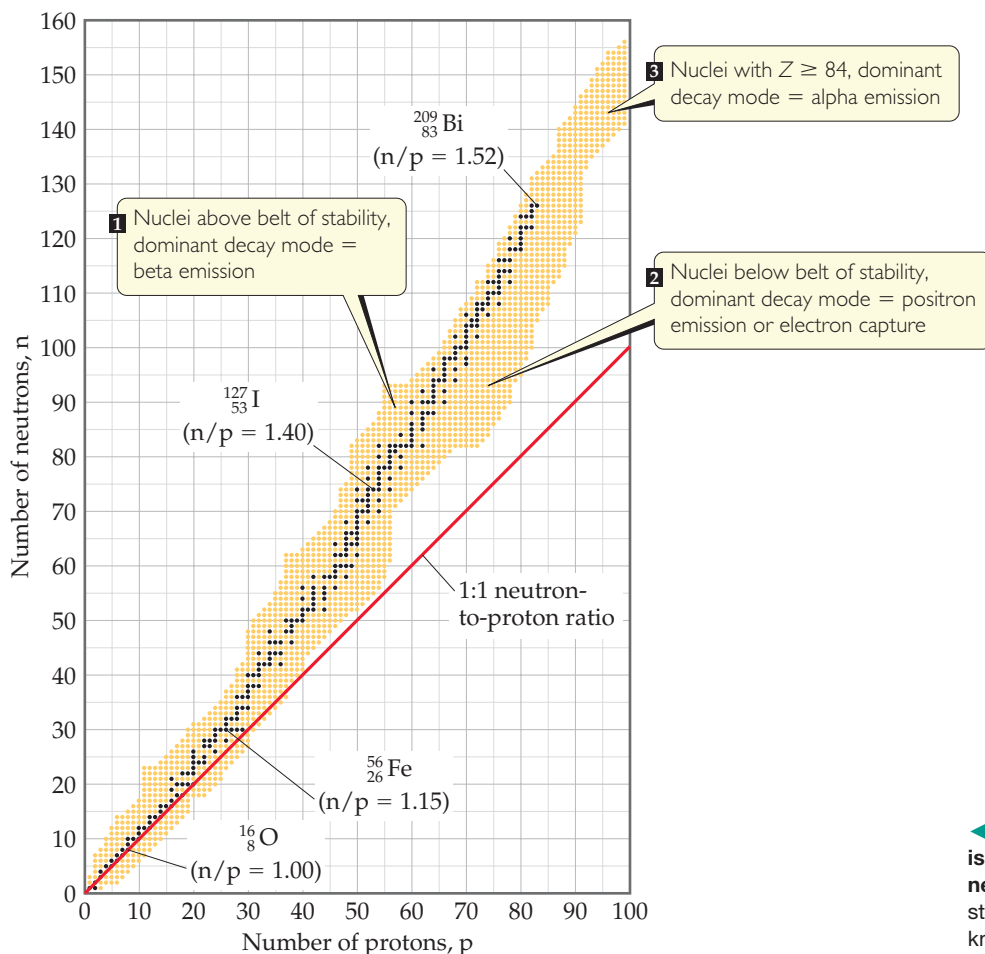

PRACTICE EXERCISE

Predict the mode of decay of (a) plutonium-239, (b) indium-120.

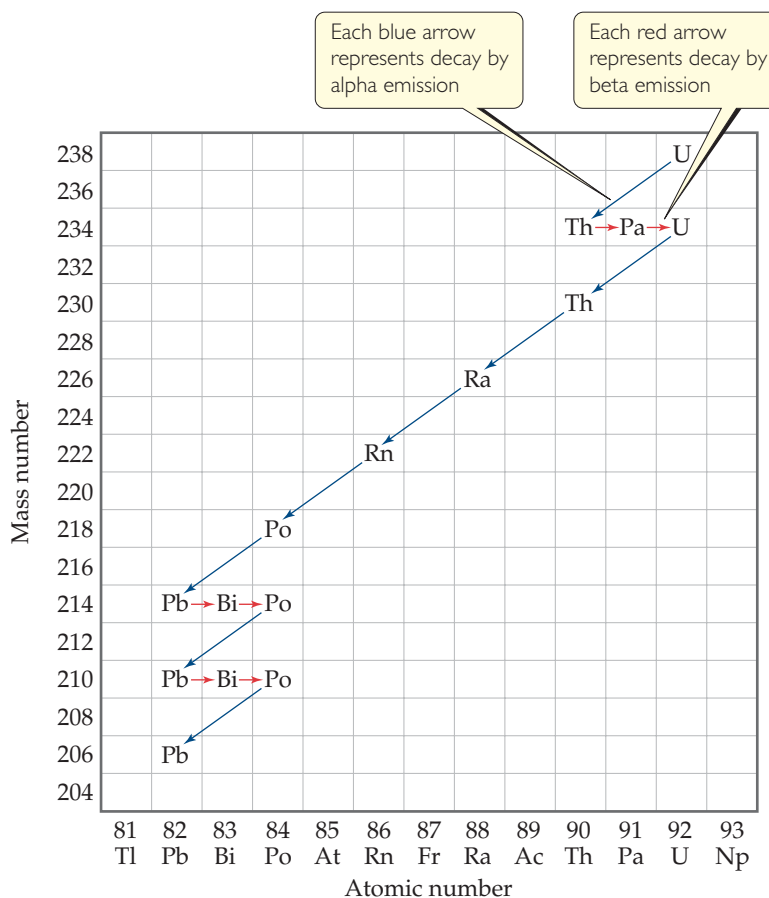

Answers: (a) α decay, (b) β emission

GO FIGURE

Estimate the optimal number of neutrons for a nucleus containing 70 protons.

◀ **FIGURE 21.2** Stable and radioactive isotopes as a function of numbers of neutrons and protons in a nucleus. The stable nuclei (dark blue dots) define a region known as the belt of stability.

► **FIGURE 21.3** Nuclear disintegration series for uranium-238. The decay continues until the stable nucleus $^{206}_{82}\text{Pb}$ is formed.

Radioactive Series

Some nuclei cannot gain stability by a single emission. Consequently, a series of successive emissions occurs as shown for uranium-238 in **▲ FIGURE 21.3**. Decay continues until a stable nucleus—lead-206 in this case—is formed. A series of nuclear reactions that begins with an unstable nucleus and terminates with a stable one is known as a **radioactive series** or a **nuclear disintegration series**. Three such series occur in nature: uranium-238 to lead-206, uranium-235 to lead-207, and thorium-232 to lead-208.

Further Observations

Two further observations can help us to predict stable nuclei:

- Nuclei with the **magic numbers** of 2, 8, 20, 28, 50, or 82 protons or 2, 8, 20, 28, 50, 82, or 126 neutrons are generally more stable than nuclei that do not contain these numbers of nucleons.
- Nuclei with even numbers of protons, neutrons, or both are more likely to be stable than those with odd numbers of protons and/or neutrons. Approximately 60% of stable nuclei have an even number of both protons and neutrons, whereas less than 2% have odd numbers of both (**◀ TABLE 21.4**).

TABLE 21.4 • Number of Stable Isotopes with Even and Odd Numbers of Protons and Neutrons

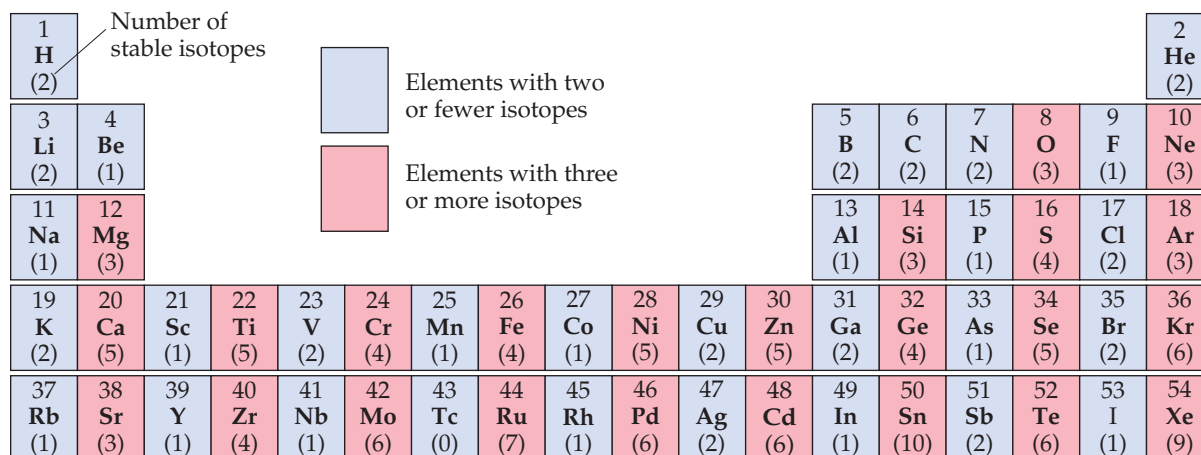

Number of Stable Isotopes	Proton Number	Neutron Number
157	Even	Even
53	Even	Odd
50	Odd	Even
5	Odd	Odd

These observations can be understood in terms of the *shell model of the nucleus*, in which nucleons are described as residing in shells analogous to the shell structure for electrons in atoms. Just as certain numbers of electrons correspond to stable filled-shell electron configurations, so also the magic numbers of nucleons represent filled shells in nuclei.

There are several examples of the stability of nuclei with magic numbers of nucleons. For example, the radioactive series in Figure 21.3 ends with the stable $^{206}_{82}\text{Pb}$ nucleus, which has a magic number of protons (82). Another example is the observation that tin, which has a magic number of protons (50), has ten stable isotopes, more than any other element.

GO FIGURE

Among the elements shown here, how many have an even number of protons and fewer than three stable isotopes? How many have an odd number of protons and more than two stable isotopes?

▲ FIGURE 21.4 Number of stable isotopes for elements 1–54.

Evidence also suggests that pairs of protons and pairs of neutrons have a special stability, analogous to the pairs of electrons in molecules. This evidence accounts for the second observation noted earlier, that stable nuclei with an even number of protons and/or neutrons are far more numerous than those with odd numbers. The preference for even numbers of protons is illustrated in ▲ FIGURE 21.4, which shows the number of stable isotopes for all elements up to Xe. Notice that once we move past nitrogen, the elements with an odd number of protons invariably have fewer stable isotopes than their neighbors with an even number of protons.

GIVE IT SOME THOUGHT

What can you say about the number of neutrons in the stable isotopes of fluorine, sodium, aluminum, and phosphorus?

SAMPLE EXERCISE 21.4 Predicting Nuclear Stability

Predict which of these nuclei are especially stable: ${}^4_2\text{He}$, ${}^{40}_{20}\text{Ca}$, ${}^{98}_{43}\text{Tc}$.

SOLUTION

Analyze We are asked to identify especially stable nuclei, given their mass numbers and atomic numbers.

Plan We look to see whether the numbers of protons and neutrons correspond to magic numbers.

Solve The ${}^4_2\text{He}$ nucleus (the alpha particle) has a magic number of both protons (2) and neutrons (2) and is very stable. The ${}^{40}_{20}\text{Ca}$ nucleus also has a magic number of both protons (20) and neutrons (20) and is especially stable.

The ${}^{98}_{43}\text{Tc}$ nucleus does not have a magic number of either protons or neutrons. In fact, it has an odd number of both protons (43) and neutrons (55). There are very few stable nuclei with odd numbers of both protons and neutrons. Indeed, technetium-98 is radioactive.

PRACTICE EXERCISE

Which of the following nuclei would you expect to exhibit a special stability: ${}^{118}_{50}\text{Sn}$, ${}^{210}_{85}\text{At}$, ${}^{208}_{82}\text{Pb}$?

Answer: ${}^{118}_{50}\text{Sn}$, ${}^{208}_{82}\text{Pb}$

21.3 NUCLEAR TRANSMUTATIONS

Thus far we have examined nuclear reactions in which a nucleus decays spontaneously. A nucleus can also change identity if it is struck by a neutron or by another nucleus. Nuclear reactions induced in this way are known as **nuclear transmutations**.

In 1919, Ernest Rutherford performed the first conversion of one nucleus into another, using alpha particles emitted by radium to convert nitrogen-14 into oxygen-17:

Such reactions have allowed scientists to synthesize hundreds of radioisotopes in the laboratory.

Nuclear transmutations are sometimes represented by listing, in order, the target nucleus, the bombarding particle, the ejected particle, and the product nucleus. Using this condensed notation, Equation 21.8 becomes

SAMPLE EXERCISE 21.5 Writing a Balanced Nuclear Equation

Write the balanced nuclear equation for the process summarized as ${}^{27}_{13}\text{Al}(n, \alpha){}^{24}_{11}\text{Na}$.

SOLUTION

Analyze We must go from the condensed descriptive form of the reaction to the balanced nuclear equation.

Plan We arrive at the balanced equation by writing n and α , each with its associated subscripts and superscripts.

Solve The n is the abbreviation for a neutron (1_0n) and α represents an alpha particle (${}^4_2\text{He}$). The neutron is the bombarding particle, and the alpha particle is a product. Therefore, the nuclear equation is

PRACTICE EXERCISE

Write the condensed version of the nuclear reaction

Answer: ${}^{16}_8\text{O}(p, \alpha){}^{13}_7\text{N}$

Accelerating Charged Particles

Alpha particles and other positively charged particles must move very fast to overcome the electrostatic repulsion between them and the target nucleus. The higher the nuclear charge on either the bombarding particle or the target nucleus, the faster the bombarding particle must move to bring about a nuclear reaction. Many methods have been devised to accelerate charged particles, using strong magnetic and electrostatic fields. These **particle accelerators**, popularly called “atom smashers,” bear such names as *cyclotron* and *synchrotron*.

A common theme in all particle accelerators is the need to create charged particles so that they can be manipulated by electrical and magnetic fields. The tubes through which the particles move must be kept at high vacuum so that the particles do not inadvertently collide with any gas-phase molecules.

► **FIGURE 21.5** shows the Relativistic Heavy Ion Collider (RHIC) located at Brookhaven National Laboratory. This facility and the Large Hadron Collider (LHC) at CERN (Conseil Européen pour la Recherche Nucléaire) near Geneva are two of the largest particle accelerators in the world. Both LHC and RHIC are capable of accelerating protons, as well as heavy ions such as gold and lead, to speeds approaching the speed

▲ FIGURE 21.5 The Relativistic Heavy Ion Collider. This particle accelerator is located at Brookhaven National Laboratory on Long Island, New York.

of light. Scientists study the outcomes of collisions involving these ultra-high-energy particles. These experiments are used to investigate the fundamental structure of matter and ultimately answer questions about the beginning of the universe.

Reactions Involving Neutrons

Most synthetic isotopes used in medicine and scientific research are made using neutrons as the bombarding particles. Because neutrons are neutral, they are not repelled by the nucleus. Consequently, they do not need to be accelerated to cause nuclear reactions. The neutrons are produced in nuclear reactors. For example, cobalt-60, which is used in cancer radiation therapy, is produced by neutron capture. Iron-58 is placed in a nuclear reactor and bombarded by neutrons to trigger the reactions sequence

▲ GIVE IT SOME THOUGHT

Can an electrostatic or magnetic field be used to accelerate neutrons in a particle accelerator? Why or why not?

Transuranium Elements

Nuclear transmutations have been used to produce the elements with atomic number above 92, collectively known as the **transuranium elements** because they follow

uranium in the periodic table. Elements 93 (neptunium, Np) and 94 (plutonium, Pu) were produced in 1940 by bombarding uranium-238 with neutrons:

Elements with still larger atomic numbers are normally formed in small quantities in particle accelerators. Curium-242, for example, is formed when a plutonium-239 target is bombarded with accelerated alpha particles:

In 1996 a team of European scientists based in Germany synthesized element 112, copernicium, Cn, by bombarding a lead target continuously for three weeks with a beam of zinc atoms:

Amazingly, their discovery was based on the detection of only one atom of the new element, which decays after roughly 100 μs by alpha decay to form darmstadtium-273 (element 110). Within one minute, another five alpha decays take place producing fermium-253 (element 100). The finding has been verified in both Japan and Russia. More recently, scientists have reported the synthesis of elements 113 through 118. These results have yet to be confirmed by the International Union for Pure and Applied Chemistry, although the results look promising. Names and symbols have not yet been chosen for these new elements.

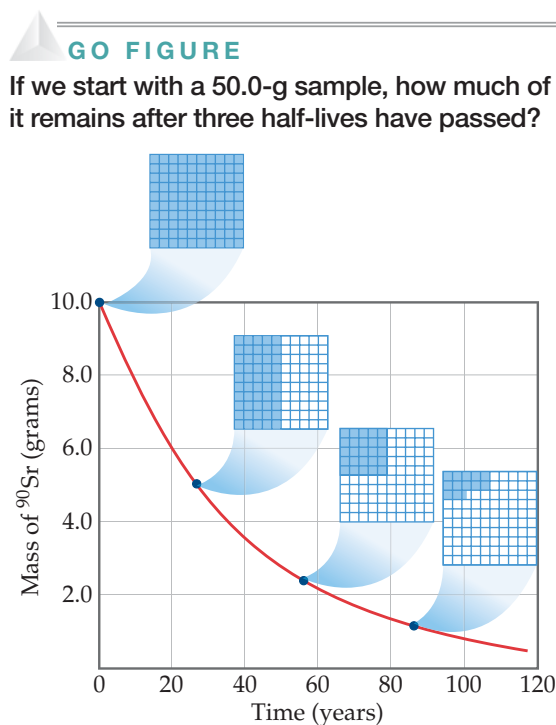

21.4 RATES OF RADIOACTIVE DECAY

Some radioisotopes, such as uranium-238, are found in nature even though they are not stable. Other radioisotopes do not exist in nature but can be synthesized in nuclear reactions. To understand this distinction, we must realize that different nuclei undergo radioactive decay at different rates. Many radioisotopes decay essentially completely in a matter of seconds, so we do not find them in nature. Uranium-238, on the other hand, decays very slowly. Therefore, despite its instability, we can still observe what remains from its formation in the early history of the universe.

Radioactive decay is a first-order kinetic process. Recall that a first-order process has a characteristic **half-life**, which is the time required for half of any given quantity of a substance to react. [Section 14.4](#) Nuclear decay rates are commonly expressed in terms of half-lives. Each isotope has its own characteristic half-life. For example, the half-life of strontium-90 is 28.8 yr ([FIGURE 21.6](#)). If we start with 10.0 g of strontium-90, only 5.0 g of that isotope remains after 28.8 yr, 2.5 g remains after another 28.8 yr, and so on. Strontium-90 decays to yttrium-90:

Half-lives as short as millionths of a second and as long as billions of years are known. The half-lives of some radioisotopes are listed in [TABLE 21.5](#). One important feature of half-lives for nuclear decay is that they are unaffected by external conditions such as temperature, pressure, or state of chemical combination. Unlike toxic chemicals, therefore, radioactive atoms cannot be rendered harmless by chemical reaction or by any other practical treatment. At this point, we can do nothing but allow these nuclei to lose radioactivity at their characteristic rates. In the meantime, we must take precautions to prevent radioisotopes, such as those produced in nuclear power plants (Section 21.7), from entering the environment because of the damage radiation can cause.

▲ FIGURE 21.6 Decay of a 10.0-g sample of strontium-90 ($t_{1/2} = 28.8$ yr). The 10×10 grids show how much of the radioactive isotope remains after various amounts of time.

TABLE 21.5 • The Half-Lives and Type of Decay for Several Radioisotopes

	Isotope	Half-Life (yr)	Type of Decay
Natural radioisotopes	$^{238}_{92}\text{U}$	4.5×10^9	Alpha
	$^{235}_{92}\text{U}$	7.0×10^8	Alpha
	$^{232}_{90}\text{Th}$	1.4×10^{10}	Alpha
	$^{40}_{19}\text{K}$	1.3×10^9	Beta
	$^{14}_6\text{C}$	5715	Beta
Synthetic radioisotopes	$^{239}_{94}\text{Pu}$	24,000	Alpha
	$^{137}_{55}\text{Cs}$	30	Beta
	$^{90}_{38}\text{Sr}$	28.8	Beta
	$^{131}_{53}\text{I}$	0.022	Beta

SAMPLE EXERCISE 21.6 Calculation Involving Half-Lives

The half-life of cobalt-60 is 5.3 yr. How much of a 1.000-mg sample of cobalt-60 is left after 15.9 yr?

SOLUTION

Analyze We are given the half-life for cobalt-60 and asked to calculate the amount of cobalt-60 remaining from an initial 1.000-mg sample after 15.9 yr.

Plan We will use the fact that the amount of a radioactive substance decreases by 50% for every half-life that passes.

Solve Because $5.3 \times 3 = 15.9$, 15.9 yr is three half-lives for cobalt-60. At the end of one half-life, 0.500 mg of cobalt-60 remains, 0.250 mg at the end of two half-lives, and 0.125 mg at the end of three half-lives.

PRACTICE EXERCISE

Carbon-11, used in medical imaging, has a half-life of 20.4 min. The carbon-11 nuclides are formed, and the carbon atoms are then incorporated into an appropriate compound. The resulting sample is injected into a patient, and the medical image is obtained. If the entire process takes five half-lives, what percentage of the original carbon-11 remains at this time?

Answer: 3.12%

Radiometric Dating

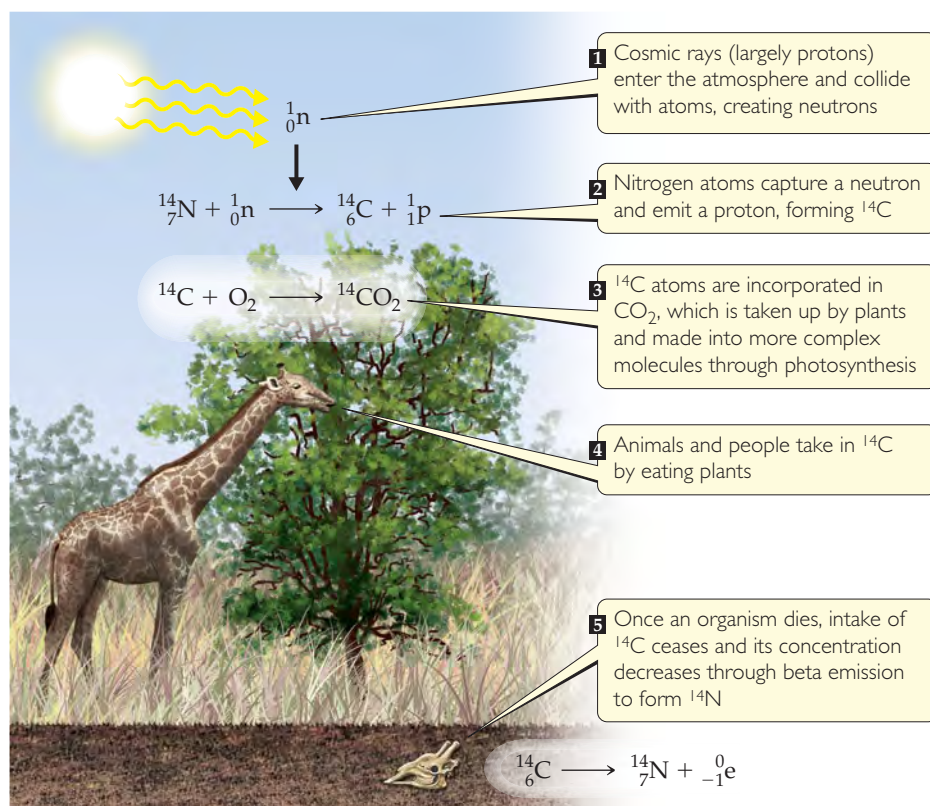

Because the half-life of any particular nuclide is constant, the half-life can serve as a nuclear clock to determine the age of objects. The method of dating objects based on their isotopes and isotope abundances is called *radiometric dating*.

When carbon-14 is used in radiometric dating, the technique is known as *radiocarbon dating*. The procedure is based on the formation of carbon-14 as neutrons created by cosmic rays in the upper atmosphere convert nitrogen-14 into carbon-14 (► **FIGURE 21.7**). The ^{14}C reacts with oxygen to form $^{14}\text{CO}_2$ in the atmosphere, and this “labeled” CO_2 is taken up by plants and introduced into the food chain through photosynthesis. This process provides a small but reasonably constant source of carbon-14, which is radioactive and undergoes beta decay with a half-life of 5715 yr:

Because a living plant or animal has a constant intake of carbon compounds, it is able to maintain a ratio of carbon-14 to carbon-12 that is nearly identical with that of the atmosphere. Once the organism dies, however, it no longer ingests carbon compounds to replenish the carbon-14 lost through radioactive decay. The ratio of carbon-14 to carbon-12 therefore decreases. By measuring this ratio and comparing it with that of the atmosphere, we can estimate the age of an object. For example, if the ratio diminishes to half that of the atmosphere, we can conclude that the object is one half-life, or 5715 yr old.

This method cannot be used to date objects older than about 50,000 yr because after this length of time the radioactivity is too low to be measured accurately.

► **FIGURE 21.7** Creation and distribution of carbon-14. The ratio of carbon-14 to carbon-12 in a dead animal or plant is related to the time since death occurred.

In radiocarbon dating, a reasonable assumption is that the ratio of carbon-14 to carbon-12 in the atmosphere has been relatively constant for the past 50,000 yr. However, because variations in solar activity control the amount of carbon-14 produced in the atmosphere, that ratio can fluctuate. We can correct for this effect by using other kinds of data. Recently scientists have compared carbon-14 data with data from tree rings, corals, lake sediments, ice cores, and other natural sources to correct variations in the carbon-14 “clock” back to 26,000 yr.

Other isotopes can be similarly used to date other types of objects. For example, it takes 4.5×10^9 yr for half of a sample of uranium-238 to decay to lead-206. The age of rocks containing uranium can therefore be determined by measuring the ratio of lead-206 to uranium-238. If the lead-206 had somehow become incorporated into the rock by normal chemical processes instead of by radioactive decay, the rock would also contain large amounts of the more abundant isotope lead-208. In the absence of large amounts of this “geonormal” isotope of lead, it is assumed that all of the lead-206 was at one time uranium-238.

The oldest rocks found on Earth are approximately 3×10^9 yr old. This age indicates that Earth’s crust has been solid for at least this length of time. Scientists estimate that it required 1×10^9 to 1.5×10^9 yr for Earth to cool and its surface to become solid, making the age of Earth 4.0 to 4.5×10^9 yr.

Calculations Based on Half-Life

So far, our discussion has been mainly qualitative. We now consider the topic of half-lives from a more quantitative point of view. This approach enables us to determine the half-life of a radioisotope or the age of an object.

As noted earlier, radioactive decay is a first-order kinetic process. Its rate, therefore, is proportional to the number of radioactive nuclei N in a sample:

$$\text{Rate} = kN \quad [21.18]$$

The first-order rate constant, k , is called the *decay constant*.

The rate at which a sample decays is called its **activity**, and it is often expressed as number of disintegrations per unit time. The **becquerel** (Bq) is the SI unit for expressing activity. A becquerel is defined as one nuclear disintegration per second. An older,

but still widely used, unit of activity is the **curie** (Ci), defined as 3.7×10^{10} disintegrations per second, which is the rate of decay of 1 g of radium. Thus, a 4.0-mCi sample of cobalt-60 undergoes

$$4.0 \times 10^{-3} \text{ Ci} \times \frac{3.7 \times 10^{10} \text{ disintegrations/s}}{1 \text{ Ci}} = 1.5 \times 10^8 \text{ disintegrations/s}$$

and so has an activity of 1.5×10^8 Bq.

As a radioactive sample decays, the amount of radiation emanating from the sample decays as well. For example, the half-life of cobalt-60 is 5.26 yr. The 4.0-mCi sample of cobalt-60 would, after 5.26 yr, have a radiation activity of 2.0 mCi, or 7.5×10^7 Bq.

GIVE IT SOME THOUGHT

Why can't spontaneous radioactive decay be a zero-order or second-order kinetic process?

As we saw in Section 14.4, a first-order rate law can be transformed into the equation

$$\ln \frac{N_t}{N_0} = -kt \quad [21.19]$$

In this equation t is the time interval of decay, k is the decay constant, N_0 is the initial number of nuclei (at time zero), and N_t is the number remaining after the time interval. Both the mass of a particular radioisotope and its activity are proportional to the number of radioactive nuclei. Thus, either the ratio of the mass at any time t to the mass at time $t = 0$ or the ratio of the activities at time t and $t = 0$ can be substituted for N_t/N_0 in Equation 21.19.

From Equation 21.19 we can obtain the relationship between the decay constant, k , and half-life, $t_{1/2}$: ∞ (Section 14.4)

$$k = \frac{0.693}{t_{1/2}} \quad [21.20]$$

where we have used the value $\ln(N_t/N_0) = \ln(0.5) = -0.693$ for one half-life. Thus, if we know the value of either the decay constant or the half-life, we can calculate the value of the other.

GIVE IT SOME THOUGHT

- Would doubling the mass of a radioactive sample change the activity of the sample?
- Would doubling the mass change the half-life for the radioactive decay?

SAMPLE EXERCISE 21.7 Calculating the Age of a Mineral

A rock contains 0.257 mg of lead-206 for every milligram of uranium-238. The half-life for the decay of uranium-238 to lead-206 is 4.5×10^9 yr. How old is the rock?

SOLUTION

Analyze We are told that a rock sample has a certain amount of lead-206 for every unit mass of uranium-238 and asked to estimate the age of the rock.

Plan Lead-206 is the product of the radioactive decay of uranium-238. We will assume that the only source of lead-206 in the rock is from the decay of uranium-238, with a known half-life. To apply first-order kinetics expressions (Equations 21.19 and 21.20) to calculate the time elapsed since the rock was formed, we first need to calculate how much initial uranium-238 there was for every 1 mg that remains today.

Solve Let's assume that the rock currently contains 1.000 mg of uranium-238 and therefore 0.257 mg of lead-206. The amount of uranium-238 in the rock when it was first formed therefore equals 1.000 mg plus the quantity that has decayed to lead-206. Because the mass of lead atoms is not the same as the mass of uranium atoms, we cannot just add 1.000 mg and 0.257 mg. We have to multiply the present mass of lead-206 (0.257 mg) by the ratio of the mass number of uranium to that of lead, into which it has decayed. Therefore, the original mass of ${}^{238}_{92}\text{U}$ was

$$\begin{aligned} \text{Original } {}^{238}_{92}\text{U} &= 1.000 \text{ mg} + \frac{238}{206}(0.257 \text{ mg}) \\ &= 1.297 \text{ mg} \end{aligned}$$

Using Equation 21.20, we can calculate the decay constant for the process from its half-life:

$$k = \frac{0.693}{4.5 \times 10^9 \text{ yr}} = 1.5 \times 10^{-10} \text{ yr}^{-1}$$

Rearranging Equation 21.19 to solve for time, t , and substituting known quantities gives

$$t = -\frac{1}{k} \ln \frac{N_t}{N_0} = -\frac{1}{1.5 \times 10^{-10} \text{ yr}^{-1}} \ln \frac{1.000}{1.297} = 1.7 \times 10^9 \text{ yr}$$

Comment To check this result, you could use the fact that the decay of uranium-237 to lead-207 has a half-life of 7×10^8 yr and measure the relative amounts of uranium-237 and lead-207 in the rock.

PRACTICE EXERCISE

A wooden object from an archeological site is subjected to radiocarbon dating. The activity due to ^{14}C is measured to be 11.6 disintegrations per second. The activity of a carbon sample of equal mass from fresh wood is 15.2 disintegrations per second. The half-life of ^{14}C is 5715 yr. What is the age of the archeological sample?

Answer: 2230 yr

We can also use measurements of radioactive activity to determine the half-life of a radioactive isotope, as the next sample exercise shows.

SAMPLE EXERCISE 21.8 Calculations Involving Radioactive Decay

If we start with 1.000 g of strontium-90, 0.953 g will remain after 2.00 yr. (a) What is the half-life of strontium-90? (b) How much strontium-90 will remain after 5.00 yr? (c) What is the initial activity of the sample in becquerels and curies?

SOLUTION

(a) Analyze We are asked to calculate a half-life, $t_{1/2}$, based on data that tell us how much of a radioactive nucleus has decayed in a time interval $t = 2.00$ yr and the information $N_0 = 1.000$ g, $N_t = 0.953$ g.

Plan We first calculate the rate constant for the decay, k , and then use that to compute $t_{1/2}$.

Solve Equation 21.19 is solved for the decay constant, k , and then Equation 21.20 is used to calculate half-life, $t_{1/2}$:

$$\begin{aligned} k &= -\frac{1}{t} \ln \frac{N_t}{N_0} = -\frac{1}{2.00 \text{ yr}} \ln \frac{0.953 \text{ g}}{1.000 \text{ g}} \\ &= -\frac{1}{2.00 \text{ yr}} (-0.0481) = 0.0241 \text{ yr}^{-1} \\ t_{1/2} &= \frac{0.693}{k} = \frac{0.693}{0.0241 \text{ yr}^{-1}} = 28.8 \text{ yr} \end{aligned}$$

(b) Analyze We are asked to calculate the amount of a radionuclide remaining after a given period of time.

Plan We need to calculate N_t , the amount of strontium present at time t , using the initial quantity, N_0 , and the rate constant for decay, k , calculated in part (a).

Solve Again using Equation 21.19, with $k = 0.0241 \text{ yr}^{-1}$, we have

$$\ln \frac{N_t}{N_0} = -kt = -(0.0241 \text{ yr}^{-1})(5.00 \text{ yr}) = -0.120$$

N_t/N_0 is calculated from $\ln(N_t/N_0) = -0.120$ using the e^x or INV LN function of a calculator:

$$\frac{N_t}{N_0} = e^{-0.120} = 0.887$$

Because $N_0 = 1.000$ g, we have

$$N_t = (0.887)N_0 = (0.887)(1.000 \text{ g}) = 0.887 \text{ g}$$

(c) Analyze We are asked to calculate the activity of the sample in becquerels and curies.

Plan We must calculate the number of disintegrations per atom per second and then multiply by the number of atoms in the sample.

Solve The number of disintegrations per atom per second is given by the rate constant, k :

$$k = \left(\frac{0.0241}{\text{yr}}\right)\left(\frac{1 \text{ yr}}{365 \text{ days}}\right)\left(\frac{1 \text{ day}}{24 \text{ h}}\right)\left(\frac{1 \text{ h}}{3600 \text{ s}}\right) = 7.64 \times 10^{-10} \text{ s}^{-1}$$

To obtain the total number of disintegrations per second, we calculate the number of atoms in the sample. We multiply this quantity by k , where we express k as the number of disintegrations per atom per second, to obtain the number of disintegrations per second:

$$(1.000 \text{ g } ^{90}\text{Sr})\left(\frac{1 \text{ mol } ^{90}\text{Sr}}{90 \text{ g } ^{90}\text{Sr}}\right)\left(\frac{6.022 \times 10^{23} \text{ atoms Sr}}{1 \text{ mol } ^{90}\text{Sr}}\right) = 6.7 \times 10^{21} \text{ atoms } ^{90}\text{Sr}$$

$$\begin{aligned} \text{Total disintegrations/s} &= \left(\frac{7.64 \times 10^{-10} \text{ disintegrations}}{\text{atom} \cdot \text{s}}\right)(6.7 \times 10^{21} \text{ atoms}) \\ &= 5.1 \times 10^{12} \text{ disintegrations/s} \end{aligned}$$

Because 1 Bq is one disintegration per second, the activity is 5.1×10^{12} Bq. The activity in curies is given by

$$(5.1 \times 10^{12} \text{ disintegrations/s})\left(\frac{1 \text{ Ci}}{3.7 \times 10^{10} \text{ disintegrations/s}}\right) = 1.4 \times 10^2 \text{ Ci}$$

We have used only two significant figures in products of these calculations because we do not know the atomic weight of ^{90}Sr to more than two significant figures without looking it up in a special source.

PRACTICE EXERCISE

A sample to be used for medical imaging is labeled with ^{18}F , which has a half-life of 110 min. What percentage of the original activity in the sample remains after 300 min?

Answer: 15.1%

21.5 DETECTION OF RADIOACTIVITY

A variety of methods have been devised to detect emissions from radioactive substances. Henri Becquerel discovered radioactivity because radiation caused fogging of photographic plates, and since that time photographic plates and film have been used to detect radioactivity. The radiation affects photographic film in much the same way as X-rays do. The greater the extent of exposure to radiation, the darker the area of the developed negative. People who work with radioactive substances carry film badges to record the extent of their exposure to radiation (▼ FIGURE 21.8).

Radioactivity can also be detected and measured by a Geiger counter. The operation of this device is based on the fact that radiation is able to ionize matter. The ions and electrons produced by the ionizing radiation permit conduction of an electrical current. The basic design of a Geiger counter is shown in ► FIGURE 21.9. A current pulse between the anode and the metal cylinder occurs whenever entering radiation produces ions. Each pulse is counted in order to estimate the amount of radiation.

◀ **FIGURE 21.8** Badge dosimeters monitor the extent to which the individual has been exposed to high-energy radiation. The radiation dose is determined from the extent of darkening of the film in the dosimeter.

► **FIGURE 21.9** Schematic drawing of a Geiger counter.

GIVE IT SOME THOUGHT

Will alpha, beta, and gamma rays pass through the window of a Geiger counter with equal efficiency?

Substances that are electronically excited by radiation can also be used to detect and measure radiation. For example, some substances excited by radiation give off light as electrons return to their lower-energy states. These substances are called *phosphors*. Different substances respond to different particles. Zinc sulfide, for example, responds to alpha particles. An instrument called a scintillation counter is used to detect and measure radiation, based on the tiny flashes of light produced when radiation strikes a suitable phosphor. The flashes of light are magnified electronically and counted to measure the amount of radiation.

Radiotracers

Because radioisotopes can be detected readily, they can be used to follow an element through its chemical reactions. The incorporation of carbon atoms from CO_2 into glucose during photosynthesis, for example, has been studied using CO_2 enriched in carbon-14:

The use of the carbon-14 label provides direct experimental evidence that carbon dioxide in the environment is chemically converted to glucose in plants. Analogous labeling experiments using oxygen-18 show that the O_2 produced during photosynthesis comes from water, not carbon dioxide. When it is possible to isolate and purify intermediates and products from reactions, detection devices such as scintillation counters can be used to “follow” the radioisotope as it moves from starting material through intermediates to final product. These types of experiments are useful for identifying elementary steps in a reaction mechanism.  (Section 14.6)

The use of radioisotopes is possible because all isotopes of an element have essentially identical chemical properties. When a small quantity of a radioisotope is mixed with the naturally occurring stable isotopes of the same element, all the isotopes go through the same reactions together. The element’s path is revealed by the radioactivity of the radioisotope. Because the radioisotope can be used to trace the path of the element, it is called a **radiotracer**.

CHEMISTRY AND LIFE

MEDICAL APPLICATIONS
OF RADIOTRACERS

Radiotracers have found wide use as diagnostic tools in medicine. ▼ **TABLE 21.6** lists some radiotracers and their uses. These radioisotopes are incorporated into a compound that is administered to the patient, usually intravenously. The diagnostic use of these isotopes

TABLE 21.6 • Some Radionuclides Used as Radiotracers

Nuclide	Half-Life	Area of the Body Studied
Iodine-131	8.04 days	Thyroid
Iron-59	44.5 days	Red blood cells
Phosphorus-32	14.3 days	Eyes, liver, tumors
Technetium-99	6.0 hours	Heart, bones, liver, and lungs
Thallium-201	73 hours	Heart, arteries
Sodium-24	14.8 hours	Circulatory system

is based on the ability of the radioactive compound to localize and concentrate in the organ or tissue under investigation. Iodine-131, for example, has been used to test the activity of the thyroid gland. This gland is the only important user of iodine in the body. The patient drinks a solution of NaI containing iodine-131. Only a very small amount is used so that the patient does not receive a harmful dose of radioactivity. A Geiger counter placed close to the thyroid, in the neck region, determines the ability of the thyroid to take up the iodine. A normal thyroid will absorb about 12% of the iodine within a few hours.

The medical applications of radiotracers are further illustrated by positron emission tomography (PET). PET is used for clinical diagnosis of many diseases. In this method, compounds containing radionuclides that decay by positron emission are injected into a patient. These compounds are chosen to enable researchers to monitor blood flow, oxygen and glucose metabolic rates, and other biological functions. Some of the most interesting work involves the study of the brain, which depends on glucose for most of its energy. Changes in how this sugar is metabolized or used by the brain may signal a disease such as cancer, epilepsy, Parkinson's disease, or schizophrenia.

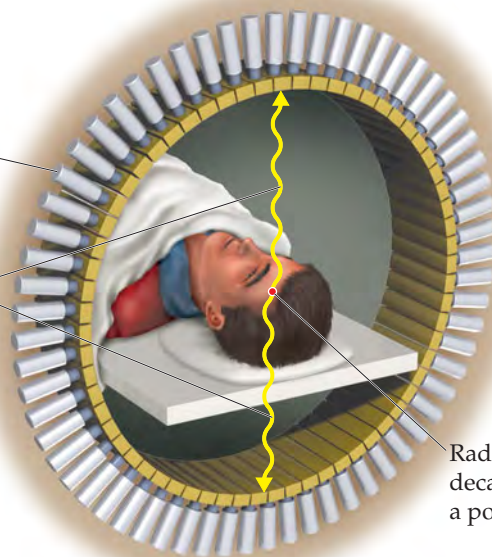

The compound to be detected in the patient must be labeled with a radionuclide that is a positron emitter. The most widely used nuclides are carbon-11 ($t_{1/2} = 20.4$ min), fluorine-18 ($t_{1/2} = 110$ min), oxygen-15 ($t_{1/2} = 2$ min), and nitrogen-13 ($t_{1/2} = 10$ min). Glucose, for example, can be labeled with carbon-11. Because the half-lives of positron emitters are so short, the chemist must quickly incorporate the radionuclide into the sugar (or other appropriate) molecule and inject the compound immediately. The patient is placed in an instrument that measures the positron emission and constructs a computer-based image of the organ in which the emitting compound is localized. When the element decays, the emitted positron quickly collides with an electron. The positron and electron are annihilated in the collision, producing two gamma rays that move in opposite directions.

The gamma rays are detected by an encircling ring of scintillation counters (◀ **FIGURE 21.10**). Because the rays move in opposite directions but were created in the same place at the same time, it is possible to accurately locate the point in the body where the radioactive isotope decayed. The nature of this image provides clues to the presence of disease or other abnormality and helps medical researchers understand how a particular disease affects the functioning of the brain. For example, the images shown in ◀ **FIGURE 21.11** reveal that levels of activity in brains of patients with Alzheimer's disease are different from the levels in those without the disease.

21.6 ENERGY CHANGES IN NUCLEAR REACTIONS

The energies associated with nuclear reactions can be considered with the aid of Einstein's celebrated equation relating mass and energy:

$$E = mc^2 \quad [21.22]$$

In this equation E stands for energy, m for mass, and c for the speed of light, 2.9979×10^8 m/s. This equation states that the mass and energy of an object are proportional. If a system loses mass, it loses energy (exothermic); if it gains mass, it gains energy (endothermic). Because the proportionality constant in the equation, c^2 , is such a large number, even small changes in mass are accompanied by large changes in energy.

The mass changes in chemical reactions are too small to detect. For example, the mass change associated with the combustion of 1 mol of CH_4 (an exothermic process) is -9.9×10^{-9} g. Because the mass change is so small, it is possible to treat chemical reactions as though mass is conserved.

The mass changes and the associated energy changes in nuclear reactions are much greater than those in chemical reactions. The mass change accompanying the radioactive decay of 1 mol of uranium-238, for example, is 50,000 times greater than that for the combustion of 1 mol of CH_4 . Let's examine the energy change for the nuclear reaction

The masses of the nuclei are ${}_{92}^{238}\text{U}$, 238.0003 amu; ${}_{90}^{234}\text{Th}$, 233.9942 amu; and ${}_2^4\text{He}$, 4.0015 amu. The mass change, Δm , is the total mass of the products minus the total mass of the reactants. The mass change for the decay of 1 mol of uranium-238 can then be expressed in grams:

$$233.9942 \text{ g} + 4.0015 \text{ g} - 238.0003 \text{ g} = -0.0046 \text{ g}$$

The fact that the system has lost mass indicates that the process is exothermic. All spontaneous nuclear reactions are exothermic.

The energy change per mole associated with this reaction is

$$\begin{aligned} \Delta E &= \Delta(mc^2) = c^2 \Delta m \\ &= (2.9979 \times 10^8 \text{ m/s})^2(-0.0046 \text{ g}) \left(\frac{1 \text{ kg}}{1000 \text{ g}} \right) \\ &= -4.1 \times 10^{11} \frac{\text{kg} \cdot \text{m}^2}{\text{s}^2} = -4.1 \times 10^{11} \text{ J} \end{aligned}$$

Notice that Δm must be converted to kilograms, the SI unit of mass, to obtain ΔE in joules, the SI unit of energy. The negative sign for the energy change indicates that energy is released in the reaction—in this case, over 400 billion joules per mole of uranium!

SAMPLE EXERCISE 21.9 Calculating Mass Change in a Nuclear Reaction

How much energy is lost or gained when 1 mol of cobalt-60 undergoes beta decay, ${}_{27}^{60}\text{Co} \longrightarrow {}_{-1}^0\text{e} + {}_{28}^{60}\text{Ni}$? The mass of a ${}_{27}^{60}\text{Co}$ atom is 59.933819 amu, and that of a ${}_{28}^{60}\text{Ni}$ atom is 59.930788 amu.

SOLUTION

Analyze We are asked to calculate the energy change in a nuclear reaction.

Plan We must first calculate the mass change in the process. We are given atomic masses, but we need the masses of the nuclei in the reaction. We calculate these by taking account of the masses of the electrons that contribute to the atomic masses.

Solve A ${}_{27}^{60}\text{Co}$ atom has 27 electrons. The mass of an electron is 5.4858×10^{-4} amu. (See the list of fundamental constants in the back inside cover.) We subtract the mass of the 27 electrons from the mass of the ${}_{27}^{60}\text{Co}$ atom to find the mass of the ${}_{27}^{60}\text{Co}$ nucleus:

$$59.933819 \text{ amu} - (27)(5.4858 \times 10^{-4} \text{ amu}) = 59.919007 \text{ amu (or } 59.919007 \text{ g/mol)}$$

Likewise, for ${}^{60}_{28}\text{Ni}$, the mass of the nucleus is

$$59.930788 \text{ amu} - (28)(5.4858 \times 10^{-4} \text{ amu}) = 59.915428 \text{ amu (or } 59.915428 \text{ g/mol)}$$

The mass change in the nuclear reaction is the total mass of the products minus the mass of the reactant:

$$\begin{aligned} \Delta m &= \text{mass of electron} + \text{mass } {}^{60}_{28}\text{Ni nucleus} - \text{mass of } {}^{60}_{27}\text{Co nucleus} \\ &= 0.00054858 \text{ amu} + 59.915428 \text{ amu} - 59.919007 \text{ amu} \\ &= -0.003030 \text{ amu} \end{aligned}$$

Thus, when a mole of cobalt-60 decays,

$$\Delta m = -0.003030 \text{ g}$$

Because the mass decreases ($\Delta m < 0$), energy is released ($\Delta E < 0$). The quantity of energy released *per mole* of cobalt-60 is calculated using Equation 21.22:

$$\begin{aligned} \Delta E &= c^2 \Delta m \\ &= (2.9979 \times 10^8 \text{ m/s})^2 (-0.003030 \text{ g}) \left(\frac{1 \text{ kg}}{1000 \text{ g}} \right) \\ &= -2.723 \times 10^{11} \frac{\text{kg}\cdot\text{m}^2}{\text{s}^2} = -2.723 \times 10^{11} \text{ J} \end{aligned}$$

PRACTICE EXERCISE

Positron emission from ${}^{11}_6\text{C} \longrightarrow {}^{11}_5\text{B} + {}^0_1\text{e}$, occurs with release of $2.87 \times 10^{11} \text{ J}$ per mole of ${}^{11}_6\text{C}$. What is the mass change per mole of ${}^{11}_6\text{C}$ in this nuclear reaction? The masses of ${}^{11}_5\text{B}$ and ${}^{11}_6\text{C}$ are 11.009305 and 11.011434 amu, respectively.

Answer: $-3.19 \times 10^{-3} \text{ g}$

Nuclear Binding Energies

Scientists discovered in the 1930s that the masses of nuclei are always less than the masses of the individual nucleons of which they are composed. For example, the helium-4 nucleus has a mass of 4.00150 amu. The mass of a proton is 1.00728 amu and that of a neutron is 1.00866 amu. Consequently, two protons and two neutrons have a total mass of 4.03188 amu:

$$\begin{aligned} \text{Mass of two protons} &= 2(1.00728 \text{ amu}) = 2.01456 \text{ amu} \\ \text{Mass of two neutrons} &= 2(1.00866 \text{ amu}) = 2.01732 \text{ amu} \\ \text{Total mass} &= 4.03188 \text{ amu} \end{aligned}$$

The mass of the individual nucleons is 0.03038 amu greater than that of the helium-4 nucleus:

$$\begin{aligned} \text{Mass of two protons and two neutrons} &= 4.03188 \text{ amu} \\ \text{Mass of } {}^4_2\text{He nucleus} &= 4.00150 \text{ amu} \\ \text{Mass difference } \Delta m &= 0.03038 \text{ amu} \end{aligned}$$

The mass difference between a nucleus and its constituent nucleons is called the **mass defect**. The origin of the mass defect is readily understood if we consider that energy must be added to a nucleus to break it into separated protons and neutrons:

The addition of energy to a system must be accompanied by a proportional increase in mass. The mass change we just calculated for the conversion of helium-4 into separated nucleons is $\Delta m = 0.03038 \text{ amu}$. Therefore, the energy required for this process is

$$\begin{aligned} \Delta E &= c^2 \Delta m \\ &= (2.9979 \times 10^8 \text{ m/s})^2 (0.03038 \text{ amu}) \left(\frac{1 \text{ g}}{6.022 \times 10^{23} \text{ amu}} \right) \left(\frac{1 \text{ kg}}{1000 \text{ g}} \right) \\ &= 4.534 \times 10^{-12} \text{ J} \end{aligned}$$

The energy required to separate a nucleus into its individual nucleons is called the **nuclear binding energy**. The mass defect and nuclear binding energy for three elements are compared in ► [TABLE 21.7](#).

TABLE 21.7 • Mass Defects and Binding Energies for Three Nuclei

Nucleus	Mass of Nucleus (amu)	Mass of Individual Nucleons (amu)	Mass Defect (amu)	Binding Energy (J)	Binding Energy per Nucleon (J)
${}^4_2\text{He}$	4.00150	4.03188	0.03038	4.53×10^{-12}	1.13×10^{-12}
${}^{56}_{26}\text{Fe}$	55.92068	56.44914	0.52846	7.90×10^{-11}	1.41×10^{-12}
${}^{238}_{92}\text{U}$	238.00031	239.93451	1.93420	2.89×10^{-10}	1.21×10^{-12}

GIVE IT SOME THOUGHT

The atomic mass of iron-56 is 55.93494 amu. Why is this number different from the mass of the nucleus given in Table 21.7?

▲ **FIGURE 21.12** Nuclear binding energies. The average binding energy per nucleon increases initially as the mass number increases and then decreases slowly. Because of these trends, fusion of light nuclei and fission of heavy nuclei are exothermic processes.

Values of binding energies per nucleon can be used to compare the stabilities of different combinations of nucleons (such as two protons and two neutrons arranged either as ${}^4_2\text{He}$ or as $2\,{}^2_1\text{H}$). ◀ **FIGURE 21.12** shows average binding energy per nucleon plotted against mass number. Binding energy per nucleon at first increases in magnitude as mass number increases, reaching about 1.4×10^{-12} J for nuclei whose mass numbers are in the vicinity of iron-56. It then decreases slowly to about 1.2×10^{-12} J for very heavy nuclei. This trend indicates that nuclei of intermediate mass numbers are more tightly bound (and therefore more stable) than those with either smaller or larger mass numbers.

This trend has two significant consequences: First, heavy nuclei gain stability and therefore give off energy if they are fragmented into two midsized nuclei. This process, known as **fission**, is used to generate energy in nuclear power plants. Second, even greater amounts of energy are released if very light

nuclei are combined, or fused together, to give more massive nuclei. This **fusion** process is the essential energy-producing process in the Sun.

GIVE IT SOME THOUGHT

Could fusing two stable nuclei that have mass numbers in the vicinity of 100 be an energy-releasing process?

21.7 NUCLEAR POWER: FISSION

Commercial nuclear power plants and most forms of nuclear weaponry depend on nuclear fission for their operation. The first nuclear fission reaction to be discovered was that of uranium-235. This nucleus, as well as those of uranium-233 and plutonium-239, undergoes fission when struck by a slow-moving neutron (▼ **FIGURE 21.13**).*

► **FIGURE 21.13** Uranium-235 fission.

This is just one of many fission patterns. In this reaction, 3.5×10^{-11} J of energy is produced per ${}^{235}\text{U}$ nucleus.

*Other heavy nuclei can be induced to undergo fission. However, these three are the only ones of practical importance.

A heavy nucleus can split in many ways. Two ways that the uranium-235 nucleus splits, for instance, are

More than 200 isotopes of 35 elements have been found among the fission products of uranium-235. Most of them are radioactive.

Slow-moving neutrons are required in fission because the process involves initial absorption of the neutron by the nucleus. The resulting more massive nucleus is often unstable and spontaneously undergoes fission. Fast neutrons tend to bounce off the nucleus, and little fission occurs.

Note that the coefficients of the product neutrons in Equations 21.24 and 21.25 are 2 and 3. On average, 2.4 neutrons are produced by every fission of a uranium-235 nucleus. If one fission produces two neutrons, the two neutrons can cause two additional fissions, each producing two neutrons. The four neutrons thereby released can produce four fissions, and so forth, as shown in ► **FIGURE 21.14**. The number of fissions and the energy released quickly escalate, and if the process is unchecked, the result is a violent explosion. Reactions that multiply in this fashion are called **chain reactions**.

For a fission chain reaction to occur, the sample of fissionable material must have a certain minimum mass. Otherwise, neutrons escape from the sample before they have the opportunity to strike other nuclei and cause additional fission. The amount of fissionable material large enough to maintain a chain reaction with a constant rate of fission is called the **critical mass**. When a critical mass of material is present, one neutron on average from each fission is subsequently effective in producing another fission and the fission continues at a constant, controllable rate. The critical mass of uranium-235 is about 50 kg for a bare sphere of the metal.*

If more than a critical mass of fissionable material is present, very few neutrons escape. The chain reaction thus multiplies the number of fissions, which can lead to a nuclear explosion. A mass in excess of a critical mass is referred to as a **supercritical mass**. The effect of mass on a fission reaction is illustrated in ▼ **FIGURE 21.15**.

► **FIGURE 21.16** shows a schematic diagram of the first atomic bomb used in warfare, the bomb dropped on Hiroshima, Japan, on August 6, 1945. To trigger a fission

▲ **FIGURE 21.14** Fission chain reaction.

▲ **FIGURE 21.15** Subcritical, critical, and supercritical fission.

▲ **FIGURE 21.16** An atomic bomb design. A conventional explosive is used to bring two subcritical masses together to form a supercritical mass.

*The exact value of the critical mass depends on the shape of the radioactive substance. The critical mass can be reduced if the radioisotope is surrounded by a material that reflects some neutrons.

A CLOSER LOOK

THE DAWNING OF THE NUCLEAR AGE

Uranium-235 fission was first achieved during the late 1930s by Enrico Fermi and coworkers in Rome and shortly thereafter by Otto Hahn and coworkers in Berlin. Both groups were trying to produce transuranium elements. In 1938, Hahn identified barium among his reaction products. He was puzzled by this observation and questioned the identification because the presence of barium was so unexpected. He sent a letter describing his experiments to Lise Meitner, a former coworker who had been forced to leave Germany because of the anti-Semitism of the Third Reich and had settled in Sweden. She surmised that Hahn's experiment indicated a nuclear process was occurring in which the uranium-235 split. She called this process *nuclear fission*.

Meitner passed word of this discovery to her nephew, Otto Frisch, a physicist working at Niels Bohr's institute in Copenhagen. Frisch repeated the experiment, verifying Hahn's observations, and found that tremendous energies were involved. In January 1939, Meitner and Frisch published a short article describing the reaction. In March 1939, Leo Szilard and Walter Zinn at Columbia University discovered that more neutrons are produced than are used in each fission. As we have seen, this result allows a chain reaction to occur.

News of these discoveries and an awareness of their potential use in explosive devices spread rapidly within the scientific community. Several scientists finally persuaded Albert Einstein, the most famous physicist of the time, to write a letter to President Franklin D. Roosevelt explaining the implications of these discoveries. Einstein's letter, written in August 1939, outlined the possible military applica-

tions of nuclear fission and emphasized the danger that weapons based on fission would pose if they were developed by the Nazis. Roosevelt judged it imperative that the United States investigate the possibility of such weapons. Late in 1941, the decision was made to build a bomb based on the fission reaction. An enormous research project, known as the Manhattan Project, began.

On December 2, 1942, the first artificial self-sustaining nuclear fission chain reaction was achieved in an abandoned squash court at the University of Chicago. This accomplishment led to the development of the first atomic bomb, at Los Alamos National Laboratory in New Mexico in July 1945 (▼ FIGURE 21.17). In August 1945 the United States dropped atomic bombs on two Japanese cities, Hiroshima and Nagasaki. The nuclear age had arrived.

▲ FIGURE 21.17 The Trinity test for the atom bomb developed during World War II. The first human-made nuclear explosion took place on July 16, 1945, on the Alamogordo test range in New Mexico.

▲ FIGURE 21.18 Diagram of a pressurized water reactor core.

reaction, two subcritical masses of uranium-235 are slammed together using chemical explosives. The combined masses of the uranium form a supercritical mass, which leads to a rapid, uncontrolled chain reaction and, ultimately, a nuclear explosion. The energy released by the bomb dropped on Hiroshima was equivalent to that of 20,000 tons of TNT (it therefore is called a *20-kiloton* bomb). Unfortunately, the basic design of a fission-based atomic bomb is quite simple, and the fissionable materials are potentially available to any nation with a nuclear reactor. The combination of design simplicity and materials availability has resulted in the proliferation of atomic weapons.

Nuclear Reactors

Nuclear power plants use nuclear fission to generate energy. The core of a typical nuclear reactor consists of four principal components: fuel elements, control rods, a moderator, and a primary coolant (◀ FIGURE 21.18). The fuel is a fissionable substance, such as uranium-235. The natural isotopic abundance of uranium-235 is only 0.7%, too low to sustain a chain reaction in most reactors. Therefore, the ^{235}U content of the fuel must be enriched to 3–5% for use in a reactor. The *fuel elements* contain enriched uranium in the form of UO_2 pellets encased in zirconium or stainless steel tubes.

The *control rods* are composed of materials that absorb neutrons, such as cadmium or boron. These rods regulate the flux of neutrons to keep the reaction chain self-sustaining and also prevent the reactor core from overheating.*

The probability that a neutron will trigger fission of a ^{235}U nucleus depends on the speed of the neutron. The neutrons produced by fission have high speeds (typically

*The reactor core cannot reach supercritical levels and explode with the violence of an atomic bomb because the concentration of uranium-235 is too low. However, if the core overheats, sufficient damage can lead to release of radioactive materials into the environment.

GO FIGURE

Why are nuclear power plants usually located near a large body of water?

▲ FIGURE 21.19 Basic design of a pressurized water reactor nuclear power plant.

in excess of 10,000 km/s). The function of the *moderator* is to slow down the neutrons (to speeds of a few kilometers per second) so that they can be captured more readily by the fissionable nuclei. The moderator is typically either water or graphite.

The *primary coolant* is a substance that transports the heat generated by the nuclear chain reaction away from the reactor core. In a *pressurized water reactor*, which is the most common commercial reactor design, water acts as both the moderator and the primary coolant.

The design of a nuclear power plant is basically the same as that of a power plant that burns fossil fuel (except that the burner is replaced by a reactor core). The nuclear power plant design shown in ▲ FIGURE 21.19, a pressurized water reactor, is currently the most popular. The primary coolant passes through the core in a closed system, which lessens the chance that radioactive products could escape the core. As an added safety precaution, the reactor is surrounded by a reinforced concrete *containment shell* to shield personnel and nearby residents from radiation and to protect the reactor from external forces. After passing through the reactor core, the very hot primary coolant passes through a heat exchanger where much of its heat is transferred to a *secondary coolant*, converting the latter to high-pressure steam that is used to drive a turbine. The secondary coolant is then condensed by transferring heat to an external source of water, such as a river or lake.

Approximately two-thirds of all commercial reactors are pressurized water reactors, but there are several variations on this basic design, each with advantages and disadvantages. A *boiling water reactor* generates steam by boiling the primary coolant; thus, no secondary coolant is needed. Pressurized water reactors and boiling water reactors are collectively referred to as *light water reactors* because they use H₂O as moderator and primary coolant. A *heavy water reactor* uses D₂O (D = deuterium, ²H) as moderator and primary coolant, and a *gas-cooled reactor* uses a gas, typically CO₂, as primary coolant and graphite as the moderator. Use of either D₂O or graphite as the moderator has the advantage that both substances absorb fewer neutrons than H₂O. Consequently, the uranium fuel does not need to be enriched (though the reactor can also be run with enriched fuel).

► **FIGURE 21.20** Fuel spheres used in a high-temperature pebble-bed reactor. The image on the right is an optical microscope image of a fuel particle.

In a *high-temperature pebble-bed reactor*, the fuel elements are spheres (“pebbles”) roughly the size of an orange (▲ **FIGURE 21.20**). The spheres are made of graphite, which acts as the moderator, and thousands of tiny fuel particles are embedded in the interior of each sphere. Each fuel particle is a kernel of fissionable material, typically ^{235}U in the form of UO_2 , surrounded by carbon and a coating of a ceramic material, such as SiC . Hundreds of thousands of these spheres are loosely packed in the reactor core, and helium gas, which acts as the primary coolant, flows up through the packed spheres. The reactor core operates at temperatures considerably higher than those in a light water reactor, approaching $950\text{ }^\circ\text{C}$. A pebble-bed reactor is not subject to steam explosions and does not need to be shut down to refuel. Engineers can remove spent spheres from the bottom of the reactor core and add fresh ones to the top. This design is relatively new and is not yet in commercial use.

Nuclear Waste

The fission products that accumulate as a reactor operates decrease the efficiency of the reactor by capturing neutrons. For this reason, commercial reactors must be stopped periodically to either replace or reprocess the nuclear fuel. When the fuel elements are removed from the reactor, they are initially very radioactive. It was originally intended that they be stored for several months in pools at the reactor site to allow decay of short-lived radioactive nuclei. They were then to be transported in shielded containers to reprocessing plants where the fuel would be separated from the fission products. Reprocessing plants have been plagued with operational difficulties, however, and there is intense opposition in the United States to the transport of nuclear wastes on the nation’s roads.

Even if the transportation difficulties could be overcome, the high level of radioactivity of the spent fuel makes reprocessing a hazardous operation. At present in the United States spent fuel elements are kept in storage at reactor sites. Spent fuel is reprocessed, however, in France, Russia, the United Kingdom, India, and Japan.

Storage of spent nuclear fuel poses a major problem because the fission products are extremely radioactive. It is estimated that 20 half-lives are required for their radioactivity to reach levels acceptable for biological exposure. Based on the 28.8-yr half-life of strontium-90, one of the longer-lived and most dangerous of the products, the wastes must be stored for 600 years. Plutonium-239 is one of the by-products present in spent fuel elements. It is formed by absorption of a neutron by uranium-238, followed by two successive beta emissions. (Remember that most of the uranium in the fuel elements is uranium-238.) If the elements are reprocessed, the plutonium-239 is largely recovered because it can be used as a nuclear fuel. However, if the plutonium is not removed, spent elements must be stored for a very long time because plutonium-239 has a half-life of 24,000 yr.

One approach to getting more power out of existing uranium sources and potentially reducing radioactive waste is a *fast breeder reactor*. This type of reactor is so named because it creates (“breeds”) more fissionable material than it consumes. The reactor operates without a moderator, which means the neutrons used are not slowed down. In order to capture the fast neutrons, the fuel must be highly enriched with both uranium-235 and plutonium-239. Water cannot be used as a primary coolant because it

would moderate the neutrons, and so a liquid metal, usually sodium, is used. The core is surrounded by a blanket of uranium-238 that captures neutrons that escape the core, producing plutonium-239 in the process. The plutonium can later be separated by reprocessing and used as fuel in a future cycle.

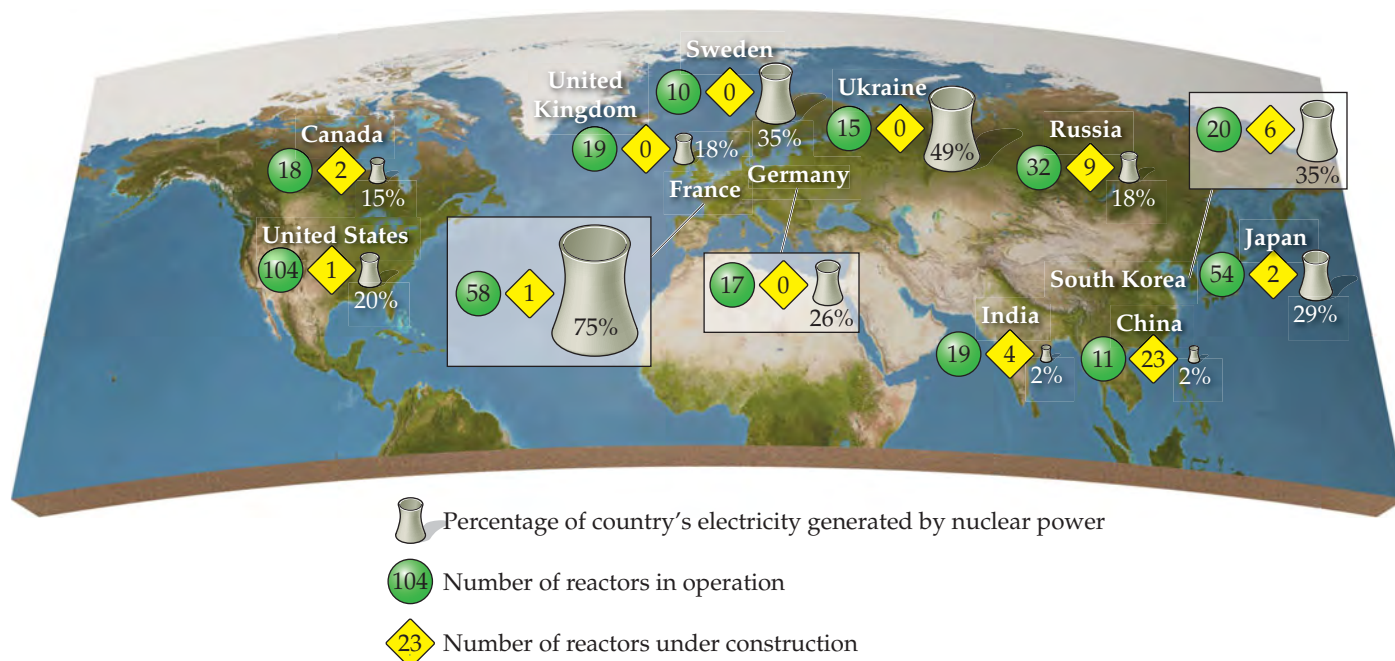

Because fast neutrons are more effective at decaying many radioactive nuclides, the material separated from the uranium and plutonium during reprocessing is less radioactive than waste from other reactors. However, generation of relatively high levels of plutonium coupled with the need for reprocessing is problematic in terms of nuclear nonproliferation. Thus, political factors coupled with increased safety concerns and higher operational costs make fast breeder reactors quite rare.

A considerable amount of research is being devoted to disposal of radioactive wastes. At present, the most attractive possibilities appear to be formation of glass, ceramic, or synthetic rock from the wastes, as a means of immobilizing them. These solid materials would then be placed in containers of high corrosion resistance and durability and buried deep underground. The U.S. Department of Energy (DOE) had designated Yucca Mountain in Nevada as a disposal site, and extensive construction has been done there. However, as of the writing of this book, the DOE has publicly stated that the Yucca Mountain site will not be used for storage, although some members of Congress are fighting this decision. The long-term solution to nuclear waste storage in the United States remains unclear. Whatever the solution finally decided on, there must be assurances that the solids and their containers will not crack from the heat generated by nuclear decay, allowing radioactivity to find its way into underground water supplies.

In spite of all these difficulties, nuclear power is making a modest comeback as an energy source. The threat of global warming has moved some organizations to propose nuclear power as a major energy source in the future. Increasing demand for power in developing Asian countries has sparked a rise in construction of new nuclear power plants in that part of the world (▼ FIGURE 21.21).

GO FIGURE

Which country has the most reactors in operation? Which country has the most reactors under construction? Which country generates the highest percentage of its electricity from nuclear power?

21.8 NUCLEAR POWER: FUSION

Energy is produced when light nuclei fuse into heavier ones. Reactions of this type are responsible for the energy produced by the Sun. Spectroscopic studies indicate that the mass composition of the Sun is 73% H, 26% He, and only 1% all other elements. The following reactions are among the numerous fusion processes believed to occur in the Sun:

Fusion is appealing as an energy source because of the availability of light isotopes on Earth and because fusion products are generally not radioactive. Despite this fact, fusion is not presently used to generate energy. The problem is that, in order for two nuclei to fuse, high temperatures and pressures are needed to overcome the electrostatic repulsion between them. Fusion reactions are therefore also known as **thermonuclear reactions**. The lowest temperature required for any fusion is about 40,000,000 K, the temperature needed to fuse deuterium and tritium:

Such high temperatures have been achieved by using an atomic bomb to initiate fusion. This is the operating principle behind a thermonuclear, or hydrogen, bomb. This approach is obviously unacceptable, however, for a power generation plant.*

Numerous problems must be overcome before fusion becomes a practical energy source. In addition to the high temperatures necessary to initiate the reaction, there is the problem of confining the reaction. No known structural material is able to withstand the enormous temperatures necessary for fusion. Research has centered on the use of an apparatus called a *tokamak*, which uses strong magnetic fields to contain and to heat the reaction. Temperatures of over 100,000,000 K have been achieved in a tokamak. Unfortunately, scientists have not yet been able to generate more power than is consumed over a sustained period of time.

21.9 RADIATION IN THE ENVIRONMENT AND LIVING SYSTEMS

We are continuously bombarded by radiation from both natural and artificial sources. We are exposed to infrared, ultraviolet, and visible radiation from the Sun; radio waves from radio and television stations; microwaves from microwave ovens; X-rays from medical procedures; and radioactivity from natural materials (► TABLE 21.8). Understanding the different energies of these various kinds of radiation is necessary in order to understand their different effects on matter.

When matter absorbs radiation, the radiation energy can cause atoms in the matter to be either excited or ionized. In general, radiation that causes ionization, called **ionizing radiation**, is far more harmful to biological systems than radiation that does not cause ionization. The latter, called **nonionizing radiation**, is generally of lower energy, such as radiofrequency electromagnetic radiation ∞ (Section 6.7) or slow-moving neutrons.

Most living tissue contains at least 70% water by mass. When living tissue is irradiated, water molecules absorb most of the energy of the radiation. Thus, it is common to define ionizing radiation as radiation that can ionize water, a process requiring a minimum energy of 1216 kJ/mol. Alpha, beta, and gamma rays (as well as X-rays and higher-energy ultraviolet radiation) possess energies in excess of this quantity and are therefore forms of ionizing radiation.

*Historically a nuclear weapon that relies solely on a fission process to release energy is called an atomic bomb, whereas one that also releases energy via a fusion reaction is called a hydrogen bomb.

A CLOSER LOOK

NUCLEAR SYNTHESIS OF THE ELEMENTS

The lightest elements—hydrogen and helium along with very small amounts of lithium and beryllium—were formed as the universe expanded in the moments following the Big Bang. All the

heavier elements owe their existence to nuclear reactions that occur in stars. These heavier elements are not all created equally, however. Carbon and oxygen are a million times more abundant than lithium and boron, for instance, and over 100 million times more abundant than beryllium (▼ FIGURE 21.22)! In fact, of the elements heavier than helium, carbon and oxygen are the most abundant. This is more than an academic curiosity given the fact that these elements, together with hydrogen, are the most important elements for life on Earth. Let's look at the factors responsible for the relatively high abundance of carbon and oxygen in the universe.

▲ FIGURE 21.22 Abundances of elements 1–10 in the solar system. Note the logarithmic scale used for the y-axis.

A star is born from a cloud of gas and dust called a *nebula*. When conditions are right, gravitational forces collapse the cloud, and its core density and temperature rise until nuclear fusion commences. Hydrogen nuclei fuse to form deuterium, ${}^2\text{H}$, and eventually ${}^4\text{He}$ through the reactions shown in Equations 21.26 through 21.29. Because ${}^4\text{He}$ has a larger binding energy than any of its immediate neighbors (Figure 21.12), these reactions release an enormous amount of energy. This process, called *hydrogen burning*, is the dominant process for most of a star's lifetime.

Once a star's supply of hydrogen is nearly exhausted, several important changes occur as the star enters the red giant phase of its life. The decrease in nuclear fusion causes the core to contract, triggering an increase in core temperature and pressure. At the same time, the outer regions expand and cool enough to make the star emit red light (thus, the name *red giant*). The star now must use ${}^4\text{He}$ nuclei as its fuel. The simplest reaction that can occur in the He-rich core, fusion of two alpha particles to form a ${}^8\text{Be}$ nucleus, does occur. However, this nucleus is highly unstable (half-life of 7×10^{-17} s) and so falls apart almost immediately. In a tiny fraction of cases, however, a third ${}^4\text{He}$ collides with a ${}^8\text{Be}$ nucleus before it decays, forming carbon-12 through the triple-alpha process:

Some of the ${}^{12}_6\text{C}$ nuclei go on to react with alpha particles to form oxygen-16:

This stage of nuclear fusion is called *helium burning*. Notice that carbon, element 6, is formed without prior formation of elements 3, 4, and 5, explaining in part their unusually low abundance. Nitrogen is relatively abundant because it can be produced from carbon through a series of reactions involving proton capture and positron emission.

Most stars gradually cool and dim as the helium is converted to carbon and oxygen, ending their lives as *white dwarfs*. In stars that are 10 or more times more massive than our Sun, however, a more dramatic fate awaits. The extreme mass of these stars leads to much higher temperatures and pressures at the core, where a variety of fusion processes lead to synthesis of the elements from neon to sulfur. These fusion reactions are collectively called *advanced burning*.

Eventually progressively heavier elements form at the core until it becomes predominantly ${}^{56}\text{Fe}$ as shown in ◀ FIGURE 21.23. Because this is such a stable nucleus, further fusion to heavier nuclei consumes energy rather than releasing it. When this happens, the fusion reactions that power the star diminish, and immense gravitational forces lead to a dramatic collapse called a *supernova explosion*. Neutron capture coupled with subsequent radioactive decays in the dying moments of such a star are responsible for the presence of all elements heavier than iron and nickel.

Without these dramatic supernova events, heavier elements that are so familiar to us, such as silver, gold, iodine, lead, and uranium, would not exist.

**Includes lead-210 and polonium-210, daughter nuclei of uranium-238.

When ionizing radiation passes through living tissue, electrons are removed from water molecules, forming highly reactive H_2O^+ ions. An H_2O^+ ion can react with another water molecule to form an H_3O^+ ion and a neutral OH molecule:

The unstable and highly reactive OH molecule is a **free radical**, a substance with one or more unpaired electrons, as seen in the Lewis structure $\cdot\ddot{\text{O}}-\text{H}$. The OH molecule is also called the *hydroxyl radical*, and the presence of the unpaired electron is often emphasized by writing the species with a single dot, $\cdot\text{OH}$. In cells and tissues, hydroxyl radicals can attack biomolecules to produce new free radicals, which in turn attack yet other biomolecules. Thus, the formation of a single hydroxyl radical via Equation 21.31 can initiate a large number of chemical reactions that are ultimately able to disrupt the normal operations of cells.

The damage produced by radiation depends on the activity and energy of the radiation, the length of exposure, and whether the source is inside or outside the body. Gamma rays are particularly harmful outside the body because they penetrate human tissue very effectively, just as X-rays do. Consequently, their damage is not limited to the skin. In contrast, most alpha rays are stopped by skin, and beta rays are able to penetrate only about 1 cm beyond the skin surface (◀ FIGURE 21.24). Neither alpha rays nor beta rays are as dangerous as gamma rays, therefore, *unless* the radiation source somehow enters the body. Within the body, alpha rays are particularly dangerous because they transfer their energy efficiently to the surrounding tissue, causing considerable damage.

In general, the tissues damaged most by radiation are those that reproduce rapidly, such as bone marrow, blood-forming tissues, and lymph nodes. The principal effect of extended exposure to low doses of radiation is to cause cancer. Cancer is caused by damage to the growth-regulation mechanism of cells, inducing the cells to reproduce uncontrollably. Leukemia, which is characterized by excessive growth of white blood cells, is probably the major type of radiation-caused cancer.

In light of the biological effects of radiation, it is important to determine whether any levels of exposure are safe. Unfortunately, we are hampered in our attempts to set realistic standards because we do not fully understand the effects of long-term exposure. Scientists concerned with setting health standards have used the hypothesis that the effects of radiation are proportional to exposure. *Any* amount of radiation is assumed to cause some finite risk of injury, and the effects of high dosage rates are extrapolated to those of lower ones. Other scientists believe, however, that there is a threshold below which there are no radiation risks. Until scientific evidence enables us to settle the matter with some confidence, it is safer to assume that even low levels of radiation present some danger.

GO FIGURE

Why are alpha rays much more dangerous when the source of radiation is located inside the body?

▲ FIGURE 21.24 Relative penetrating abilities of alpha, beta, and gamma radiation.

Radiation Doses

Two units are commonly used to measure exposure to radiation. The **gray** (Gy), the SI unit of absorbed dose, corresponds to the absorption of 1 J of energy per kilogram of tissue. The **rad** (radiation absorbed dose) corresponds to the absorption of 1×10^{-2} J

of energy per kilogram of tissue. Thus, $1 \text{ Gy} = 100 \text{ rad}$. The rad is the unit most often used in medicine.

Not all forms of radiation harm biological materials with the same efficiency. For example, 1 rad of alpha radiation can produce more damage than 1 rad of beta radiation. To correct for these differences, the radiation dose is multiplied by a factor that measures the relative damage caused by the radiation. This multiplication factor is known as the *relative biological effectiveness*, *RBE*. The RBE is approximately 1 for gamma and beta radiation, and 10 for alpha radiation.

The exact value of the RBE varies with dose rate, total dose, and type of tissue affected. The product of the radiation dose in rads and the RBE of the radiation give the *effective dosage* in **rem** (roentgen equivalent for *man*):

$$\text{Number of rem} = (\text{number of rad})(\text{RBE}) \quad [21.32]$$

The SI unit for effective dose is the *sievert* (Sv), obtained by multiplying the RBE times the SI unit for radiation dose, the gray; because a gray is 100 times larger than a rad, $1 \text{ Sv} = 100 \text{ rem}$. The rem is the unit of radiation damage usually used in medicine.

GIVE IT SOME THOUGHT

If a 50-kg person is uniformly irradiated by 0.10-J alpha radiation, what is the absorbed dosage in rad and the effective dosage in rem?

The effects of short-term exposure to radiation appear in ▼ **TABLE 21.9**. An exposure of 600 rem is fatal to most humans. To put this number in perspective, a typical dental X-ray entails an exposure of about 0.5 mrem. The average exposure for a person in 1 year due to all natural sources of ionizing radiation (called *background radiation*) is about 360 mrem (▼ **FIGURE 21.25**).

TABLE 21.9 • Effects of Short-Term Exposures to Radiation

Dose (rem)	Effect
0–25	No detectable clinical effects
25–50	Slight, temporary decrease in white blood cell counts
100–200	Nausea; marked decrease in white blood cell counts
500	Death of half the exposed population within 30 days

◀ **FIGURE 21.25** Sources of U.S. average annual exposure to high-energy radiation. The total average annual exposure is 360 mrem. Data from “Ionizing Radiation Exposure of the Population of the United States,” Report 93, 1987, National Council on Radiation Protection.

Radon

Radon-222 is a product of the nuclear disintegration series of uranium-238 (Figure 21.3) and is continuously generated as uranium in rocks and soil decays. As Figure 21.25 indicates, radon exposure is estimated to account for more than half the 360-mrem average annual exposure to ionizing radiation.

The interplay between the chemical and nuclear properties of radon makes it a health hazard. Because radon is a noble gas, it is extremely unreactive and is therefore free to escape from the ground without chemically reacting along the way. It is readily inhaled and exhaled with no direct chemical effects. Its half-life, however, is only 3.82 days. It decays, by losing an alpha particle, into a radioisotope of polonium:

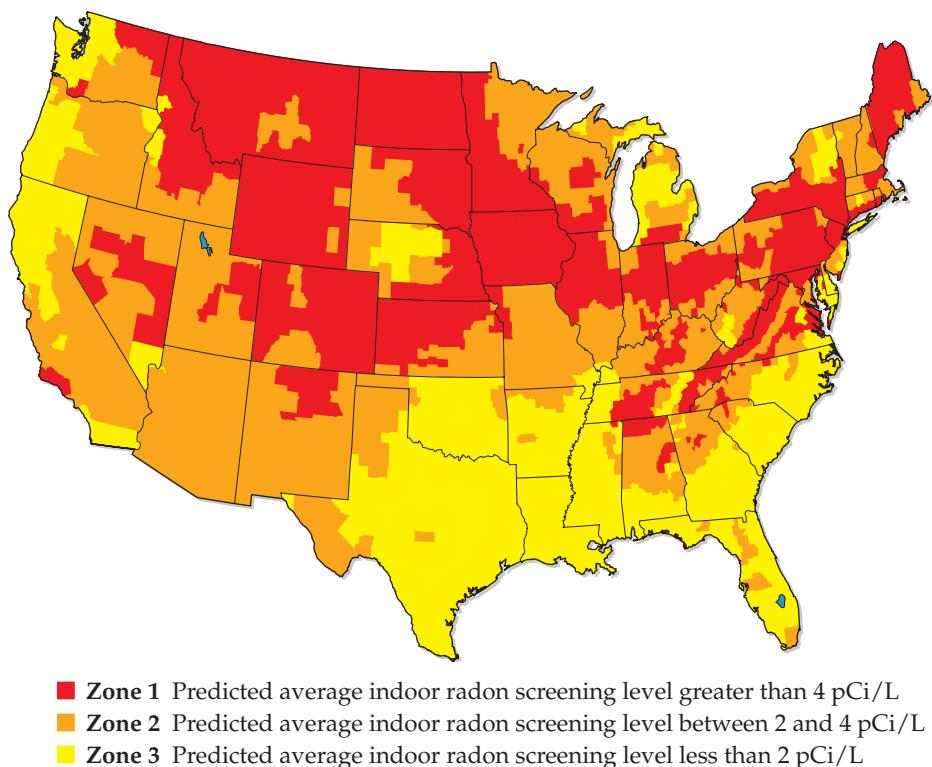

Because radon has such a short half-life and because alpha particles have a high RBE, inhaled radon is considered a probable cause of lung cancer. Even worse than the radon, however, is the decay product because polonium-218 is an alpha-emitting chemically active element that has an even shorter half-life (3.11 min) than radon-222:

When a person inhales radon, therefore, atoms of polonium-218 can become trapped in the lungs, where they bathe the delicate tissue with harmful alpha radiation. The resulting damage is estimated to contribute to 10% of all lung cancer deaths in the United States.

The U.S. Environmental Protection Agency (EPA) has recommended that radon-222 levels not exceed 4 pCi per liter of air in homes. Homes located in areas where the natural uranium content of the soil is high often have levels much greater than that (▼ FIGURE 21.26). Because of public awareness, radon-testing kits are readily available in many parts of the country.

▲ **FIGURE 21.26** EPA map of radon zones in the United States. The color coding shows average indoor radon levels as a function of geographic location.

CHEMISTRY AND LIFE

RADIATION THERAPY

Healthy cells are either destroyed or damaged by high-energy radiation, leading to physiological disorders.

This radiation can also destroy *unhealthy* cells, however, including cancerous cells. All cancers are characterized by runaway cell growth that can produce *malignant tumors*. These tumors can be caused by the exposure of healthy cells to high-energy radiation. Paradoxically, however, they can be destroyed by the same radiation that caused them because the rapidly reproducing cells of the tumors are very susceptible to radiation damage. Thus, cancerous cells are more susceptible to destruction by radiation than healthy ones, allowing radiation to be used effectively in the treatment of cancer. As early as 1904, physicians used the radiation emitted by radioactive substances to treat tumors by destroying the mass of unhealthy tissue. The treatment of disease by high-energy radiation is called *radiation therapy*.

Many radionuclides are currently used in radiation therapy. Most of them have short half-lives, meaning that they emit a great deal of radiation in a short period of time (► TABLE 21.10).

The radiation source used in radiation therapy may be inside or outside the body. In almost all cases, radiation therapy uses gamma radiation emitted by radioisotopes. Any alpha or beta radiation that is emitted concurrently can be blocked by appropriate packaging. For example, ^{192}Ir is often administered as “seeds” consisting of a core of radioactive isotope coated with 0.1 mm of platinum metal. The platinum coating stops the alpha and beta rays, but the gamma rays penetrate it readily. The radioactive seeds can be surgically implanted in a tumor.

In some cases, human physiology allows a radioisotope to be ingested. For example, most of the iodine in the human body ends up in the thyroid gland, so thyroid cancer can be treated by using large doses of ^{131}I . Radiation therapy on deep organs, where a surgical implant is impractical, often uses a ^{60}Co “gun” outside the body to shoot a beam of gamma rays at the tumor. Particle accelerators are also used as an external source of high-energy radiation for radiation therapy.

Because gamma radiation is so strongly penetrating, it is nearly impossible to avoid damaging healthy cells during radiation therapy. Many cancer patients undergoing radiation treatment experience unpleasant and dangerous side effects such as fatigue, nausea, hair loss, a weakened immune system, and occasionally even death. However, if other treatments such as *chemotherapy* (the use of drugs to combat cancer) fail, radiation therapy can be a good option.

TABLE 21.10 • Some Radioisotopes Used in Radiation Therapy

Isotope	Half-Life	Isotope	Half-Life
^{32}P	14.3 days	^{137}Cs	30 yr
^{60}Co	5.27 yr	^{192}Ir	74.2 days
^{90}Sr	28.8 yr	^{198}Au	2.7 days
^{125}I	60.25 days	^{222}Rn	3.82 days
^{131}I	8.04 days	^{226}Ra	1600 yr

SAMPLE INTEGRATIVE EXERCISE Putting Concepts Together

Potassium ion is present in foods and is an essential nutrient in the human body. One of the naturally occurring isotopes of potassium, potassium-40, is radioactive. Potassium-40 has a natural abundance of 0.0117% and a half-life $t_{1/2} = 1.28 \times 10^9$ yr. It undergoes radioactive decay in three ways: 98.2% is by electron capture, 1.35% is by beta emission, and 0.49% is by positron emission. (a) Why should we expect ^{40}K to be radioactive? (b) Write the nuclear equations for the three modes by which ^{40}K decays. (c) How many $^{40}\text{K}^+$ ions are present in 1.00 g of KCl? (d) How long does it take for 1.00% of the ^{40}K in a sample to undergo radioactive decay?

SOLUTION

(a) The ^{40}K nucleus contains 19 protons and 21 neutrons. There are very few stable nuclei with odd numbers of both protons and neutrons (Section 21.2).

(b) Electron capture is capture of an inner-shell electron by the nucleus:

Beta emission is loss of a beta particle (${}^0_{-1}\text{e}$) by the nucleus:

Positron emission is loss of a positron (${}^0_{+1}\text{e}$) by the nucleus:

(c) The total number of K^+ ions in the sample is

$$(1.00 \text{ g KCl}) \left(\frac{1 \text{ mol KCl}}{74.55 \text{ g KCl}} \right) \left(\frac{1 \text{ mol K}^+}{1 \text{ mol KCl}} \right) \left(\frac{6.022 \times 10^{23} \text{ K}^+}{1 \text{ mol K}^+} \right) = 8.08 \times 10^{21} \text{ K}^+ \text{ ions}$$

Of these, 0.0117% are $^{40}\text{K}^+$ ions:

$$(8.08 \times 10^{21} \text{ K}^+ \text{ ions}) \left(\frac{0.0117 \text{ } ^{40}\text{K}^+ \text{ ions}}{100^+ \text{ ions}} \right) = 9.45 \times 10^{17} \text{ potassium-40 ions}$$

(d) The decay constant (the rate constant) for the radioactive decay can be calculated from the half-life, using Equation 21.20:

$$k = \frac{0.693}{t_{1/2}} = \frac{0.693}{1.28 \times 10^9 \text{ yr}} = (5.41 \times 10^{-10})/\text{yr}$$

The rate equation, Equation 21.19, then allows us to calculate the time required:

$$\ln \frac{N_t}{N_0} = -kt$$

$$\ln \frac{99}{100} = -[(5.41 \times 10^{-10})/\text{yr}]t$$

$$-0.01005 = -[(5.41 \times 10^{-10})/\text{yr}]t$$

$$t = \frac{-0.01005}{(-5.41 \times 10^{-10})/\text{yr}} = 1.86 \times 10^7 \text{ yr}$$

That is, it would take 18.6 million years for just 1.00% of the ^{40}K in a sample to decay.

CHAPTER SUMMARY AND KEY TERMS

INTRODUCTION AND SECTION 21.1 The nucleus of an atom contains protons and neutrons, both of which are called **nucleons**. Reactions that involve changes in atomic nuclei are called **nuclear reactions**. Nuclei that spontaneously change by emitting radiation are said to be radioactive. Radioactive nuclei are called **radionuclides**, and the atoms containing them are called **radioisotopes**. Radionuclides spontaneously change through a process called radioactive decay. The three most important types of radiation given off as a result of radioactive decay are **alpha (α) particles** (^4_2He), **beta (β) particles** ($^0_{-1}\text{e}$), and **gamma (γ) radiation** ($^0_0\gamma$). **Positrons** (^0_1e), which are particles with the same mass as an electron but the opposite charge, can also be produced when a radioisotope decays.

In nuclear equations, reactant and product nuclei are represented by giving their mass numbers and atomic numbers, as well as their chemical symbol. The totals of the mass numbers on both sides of the equation are equal; the totals of the atomic numbers on both sides are also equal. There are four common modes of radioactive decay: **alpha decay**, which reduces the atomic number by 2 and the mass number by 4, **beta emission**, which increases the atomic number by 1 and leaves the mass number unchanged, **positron emission** and **electron capture**, both of which reduce the atomic number by 1 and leave the mass number unchanged.

SECTION 21.2 The neutron-to-proton ratio is an important factor determining nuclear stability. By comparing a nuclide's neutron-to-proton ratio with those in the band of stability, we can predict the mode of radioactive decay. In general, neutron-rich nuclei tend to emit beta particles; proton-rich nuclei tend to either emit positrons or undergo electron capture; and heavy nuclei tend to emit alpha particles. The presence of **magic numbers** of nucleons and an even number of protons and neutrons also help determine the stability of a nucleus. A nuclide may undergo a series of decay steps before a stable nuclide forms. This series of steps is called a **radioactive series** or a **nuclear disintegration series**.

SECTION 21.3 Nuclear transmutations, induced conversions of one nucleus into another, can be brought about by bombarding nuclei with either charged particles or neutrons. **Particle accelerators** increase the kinetic energies of positively charged particles, allowing these particles to overcome their electrostatic repulsion by the nucleus. Nuclear transmutations are used to produce the **transuranium elements**, those elements with atomic numbers greater than that of uranium.

SECTIONS 21.4 AND 21.5 The SI unit for the activity of a radioactive source is the **becquerel (Bq)**, defined as one nuclear disintegration per second. A related unit, the **curie (Ci)**, corresponds to 3.7×10^{10} disintegrations per second. Nuclear decay is a first-order process. The decay rate (**activity**) is therefore proportional to the number of radioactive nuclei. The **half-life** of a radionuclide, which is a constant, is the time needed for one-half of the nuclei to decay. Some radioisotopes can be used to date objects; ^{14}C , for example, is used to date organic objects. Geiger counters and scintillation counters count the emissions from radioactive samples. The ease of detection of radioisotopes also permits their use as **radiotracers** to follow elements through reactions.

SECTION 21.6 The energy produced in nuclear reactions is accompanied by measurable changes of mass in accordance with Einstein's relationship, $\Delta E = c^2 \Delta m$. The difference in mass between nuclei and the nucleons of which they are composed is known as the **mass defect**. The mass defect of a nuclide makes it possible to calculate its **nuclear binding energy**, the energy required to separate the nucleus into individual nucleons. Energy is produced when heavy nuclei split (**fission**) and when light nuclei fuse (**fusion**).

SECTIONS 21.7 AND 21.8 Uranium-235, uranium-233, and plutonium-239 undergo fission when they capture a neutron, splitting into lighter nuclei and releasing more neutrons. The neutrons produced in one fission can cause further fission reactions, which can lead to a nuclear **chain reaction**. A reaction that maintains a constant rate

is said to be critical, and the mass necessary to maintain this constant rate is called a **critical mass**. A mass in excess of the critical mass is termed a **supercritical mass**.

In nuclear reactors the fission rate is controlled to generate a constant power. The reactor core consists of fuel elements containing fissionable nuclei, control rods, a moderator, and a primary coolant. A nuclear power plant resembles a conventional power plant except that the reactor core replaces the fuel burner. There is concern about the disposal of highly radioactive nuclear wastes that are generated in nuclear power plants.

Nuclear fusion requires high temperatures because nuclei must have large kinetic energies to overcome their mutual repulsions. Fusion reactions are therefore called **thermonuclear reactions**. It is not yet possible to generate power on Earth through a controlled fusion process.

SECTION 21.9 Ionizing radiation is energetic enough to remove an electron from a water molecule; radiation with less energy is called **nonionizing radiation**. Ionizing radiation generates **free radicals**, reactive substances with one or more unpaired electrons. The effects of long-term exposure to low levels of radiation are not completely understood, but it is usually assumed that the extent of biological damage varies in direct proportion to the level of exposure.

The amount of energy deposited in biological tissue by radiation is called the radiation dose and is measured in units of gray or rad. One **gray** (Gy) corresponds to a dose of 1 J/kg of tissue. The **rad** is a smaller unit; 100 rad = 1 Gy. The effective dose, which measures the biological damage created by the deposited energy, is measured in units of rem or sievert (Sv). The **rem** is obtained by multiplying the number of rad by the relative biological effectiveness (RBE); 100 rem = 1 Sv.

KEY SKILLS

- Write balanced nuclear equations. (Section 21.1)
- Predict nuclear stability and expected type of nuclear decay from the neutron-to-proton ratio of an isotope. (Section 21.2)
- Write balanced nuclear equations for nuclear transmutations. (Section 21.3)
- Calculate ages of objects and/or the amount of a radionuclide remaining after a given period of time using the half-life of the radionuclide in question. (Section 21.4)
- Calculate mass and energy changes for nuclear reactions. (Section 21.6)
- Calculate the binding energies for nuclei. (Section 21.6)
- Describe the difference between fission and fusion. (Sections 21.7 and 21.8)
- Understand how a nuclear power plant operates and know the differences among various types of nuclear power plants. (Section 21.7)
- Understand the meaning of radiation dosage terms. (Section 21.9)
- Understand the biological effects of different kinds of radiation. (Section 21.9)

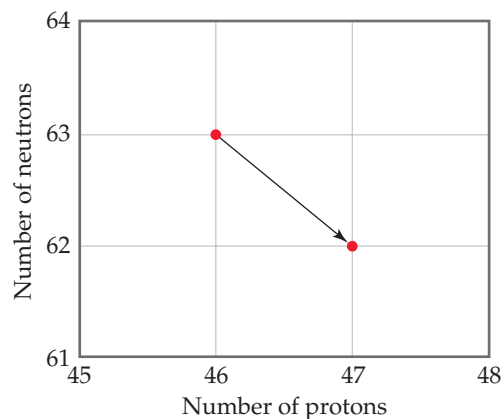

KEY EQUATIONS

- $\ln \frac{N_t}{N_0} = -kt$ [21.19] First-order rate law for nuclear decay
- $k = \frac{0.693}{t_{1/2}}$ [21.20] Relationship between nuclear decay constant and half-life; this is derived from the previous equation at $N_t = \frac{1}{2}N_0$
- $E = mc^2$ [21.22] Einstein's equation that relates mass and energy

EXERCISES

VISUALIZING CONCEPTS

- 21.1** Indicate whether each of the following nuclides lies within the belt of stability in Figure 21.2: (a) neon-24, (b) chlorine-32, (c) tin-108, (d) polonium-216. For any that do not, describe a nuclear decay process that would alter the neutron-to-proton ratio in the direction of increased stability. [Section 21.2]
- 21.2** Write the balanced nuclear equation for the reaction represented by the diagram shown here. [Section 21.2]

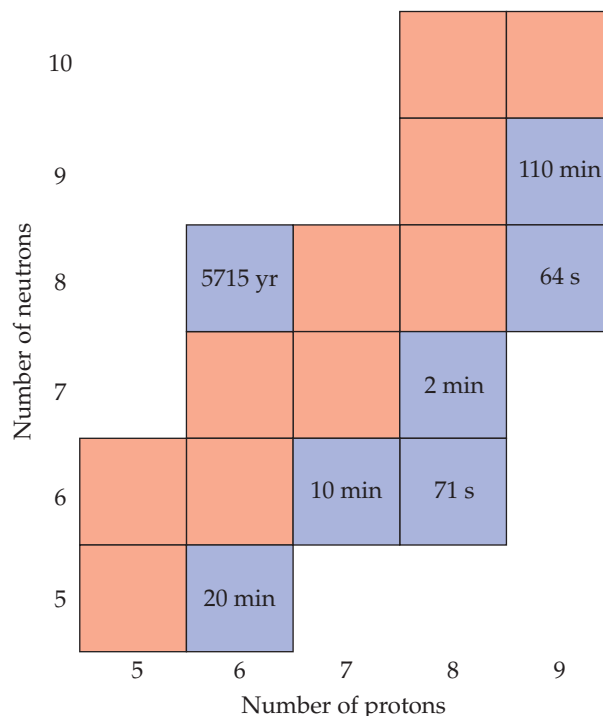

21.3 Draw a diagram similar to that shown in Exercise 21.2 that illustrates the nuclear reaction ${}^{211}_{83}\text{Bi} \longrightarrow {}^4_2\text{He} + {}^{207}_{81}\text{Tl}$. [Section 21.2]

21.4 The accompanying graph illustrates the decay of ${}^{88}_{42}\text{Mo}$, which decays via positron emission. (a) What is the half-life of the decay? (b) What is the rate constant for the decay? (c) What fraction of the original sample of ${}^{88}_{42}\text{Mo}$ remains after 12 min? (d) What is the product of the decay process? [Section 21.4]

21.5 All the stable isotopes of boron, carbon, nitrogen, oxygen, and fluorine are shown in the chart in the right hand column (in red), along with their radioactive isotopes with $t_{1/2} > 1$ min (in blue). (a) Write the chemical symbols, including mass and atomic numbers, for all of the stable isotopes. (b) Which radioactive isotopes are most likely to decay by beta emission? (c) Some of the isotopes shown are used in positron emission tomography. Which ones would you expect to be most useful for this application? (d) Which isotope would decay to 12.5%

of its original concentration after 1 hour? [Sections 21.2, 21.4, and 21.5]

21.6 The diagram shown here illustrates a fission process. (a) What is the unidentified product of the fission? (b) Use Figure 21.2 to predict whether the nuclear products of this fission reaction are stable. [Section 21.7]

RADIOACTIVITY (section 21.1)

21.7 Indicate the number of protons and neutrons in the following nuclei: (a) ${}^{55}_{22}\text{Mn}$, (b) ${}^{201}\text{Hg}$, (c) potassium-39.

21.8 Indicate the number of protons and neutrons in the following nuclei: (a) ${}^{124}_{52}\text{Te}$, (b) ${}^{37}\text{Cl}$, (c) thorium-232.

21.9 Give the symbol for (a) a neutron, (b) an alpha particle, (c) gamma radiation.

21.10 Give the symbol for (a) a proton, (b) a beta particle, (c) a positron.

21.11 Write balanced nuclear equations for the following processes: (a) rubidium-90 undergoes beta emission; (b) selenium-72 undergoes electron capture; (c) krypton-76 undergoes positron emission; (d) radium-226 emits alpha radiation.

21.12 Write balanced nuclear equations for the following transformations: (a) bismuth-213 undergoes alpha decay; (b) nitrogen-13 undergoes electron capture; (c) technetium-98 undergoes electron capture; (d) gold-188 decays by positron emission.

21.13 Decay of which nucleus will lead to the following products: (a) bismuth-211 by beta decay; (b) chromium-50 by positron emission; (c) tantalum-179 by electron capture; (d) radium-226 by alpha decay?

21.14 What particle is produced during the following decay processes: (a) sodium-24 decays to magnesium-24; (b) mercury-188 decays to gold-188; (c) iodine-122 decays to xenon-122; (d) plutonium-242 decays to uranium-238?

21.15 The naturally occurring radioactive decay series that begins with ${}^{235}_{92}\text{U}$ stops with formation of the stable ${}^{207}_{82}\text{Pb}$ nucleus. The decays proceed through a series of alpha-particle and beta-particle emissions. How many of each type of emission are involved in this series?

21.16 A radioactive decay series that begins with ${}^{232}_{90}\text{Th}$ ends with formation of the stable nuclide ${}^{208}_{82}\text{Pb}$. How many alpha-particle emissions and how many beta-particle emissions are involved in the sequence of radioactive decays?

NUCLEAR STABILITY (section 21.2)

- 21.17** Predict the type of radioactive decay process for the following radionuclides: (a) ${}^8_3\text{B}$, (b) ${}^{68}_{29}\text{Cu}$, (c) phosphorus-32, (d) chlorine-39.
- 21.18** Each of the following nuclei undergoes either beta decay or positron emission. Predict the type of emission for each: (a) tritium, ${}^3_1\text{H}$, (b) ${}^{89}_{38}\text{Sr}$, (c) iodine-120, (d) silver-102.
- 21.19** One of the nuclides in each of the following pairs is radioactive. Predict which is radioactive and which is stable: (a) ${}^{39}_{19}\text{K}$ and ${}^{40}_{19}\text{K}$, (b) ${}^{209}_{83}\text{Bi}$ and ${}^{208}_{83}\text{Bi}$, (c) nickel-58 and nickel-65. Explain.
- 21.20** One nuclide in each of these pairs is radioactive. Predict which is radioactive and which is stable: (a) ${}^{40}_{20}\text{Ca}$ and ${}^{45}_{20}\text{Ca}$, (b) ${}^{12}_6\text{C}$ and ${}^{14}_6\text{C}$, (c) lead-206 and thorium-230. Explain your choice in each case.
- 21.21** Which of the following nuclides have magic numbers of both protons and neutrons: (a) helium-4, (b) oxygen-18, (c) calcium-40, (d) zinc-66, (e) lead-208?
- 21.22** Despite the similarities in the chemical reactivity of elements in the lanthanide series, their abundances in Earth's crust vary by two orders of magnitude. This graph shows the relative abundance as a function of atomic number. How do you explain the sawtooth variation across the series?

- 21.23** Using the concept of magic numbers, explain why alpha emission is relatively common, but proton emission is nonexistent.
- 21.24** Which of the following nuclides would you expect to be radioactive: ${}^{62}_{28}\text{Ni}$, ${}^{58}_{29}\text{Cu}$, ${}^{108}_{47}\text{Ag}$, tungsten-184, polonium-206? Justify your choices.

NUCLEAR TRANSMUTATIONS (section 21.3)

- 21.25** Why are nuclear transmutations involving neutrons generally easier to accomplish than those involving protons or alpha particles?
- 21.26** In 1930 the American physicist Ernest Lawrence designed the first cyclotron in Berkeley, California. In 1937 Lawrence bombarded a molybdenum target with deuterium ions, producing for the first time an element not found in nature. What was this element? Starting with molybdenum-96 as your reactant, write a nuclear equation to represent this process.
- 21.27** Complete and balance the following nuclear equations by supplying the missing particle:
- (a) ${}^{252}_{98}\text{Cf} + {}^{10}_5\text{B} \longrightarrow 3 {}^1_0\text{n} + ?$
 (b) ${}^2_1\text{H} + {}^3_2\text{He} \longrightarrow {}^4_2\text{He} + ?$
 (c) ${}^1_1\text{H} + {}^{11}_5\text{B} \longrightarrow 3?$
 (d) ${}^{122}_{53}\text{I} \longrightarrow {}^{122}_{54}\text{Xe} + ?$
 (e) ${}^{59}_{26}\text{Fe} \longrightarrow {}^0_{-1}\text{e} + ?$
- 21.28** Complete and balance the following nuclear equations by supplying the missing particle:
- (a) ${}^{14}_7\text{N} + {}^4_2\text{He} \longrightarrow ? + {}^1_1\text{H}$
 (b) ${}^{40}_{19}\text{K} + {}^0_{-1}\text{e} \text{ (orbital electron)} \longrightarrow ?$
 (c) $? + {}^4_2\text{He} \longrightarrow {}^{30}_{14}\text{Si} + {}^1_1\text{H}$
 (d) ${}^{58}_{26}\text{Fe} + 2 {}^1_0\text{n} \longrightarrow {}^{60}_{27}\text{Co} + ?$
 (e) ${}^{235}_{92}\text{U} + {}^1_0\text{n} \longrightarrow {}^{135}_{54}\text{Xe} + 2 {}^1_0\text{n} + ?$
- 21.29** Write balanced equations for (a) ${}^{238}_{92}\text{U}(\alpha, \text{n}){}^{241}_{94}\text{Pu}$, (b) ${}^{14}_7\text{N}(\alpha, \text{p}){}^{17}_8\text{O}$, (c) ${}^{56}_{26}\text{Fe}(\alpha, \beta){}^{60}_{29}\text{Cu}$.
- 21.30** Write balanced equations for each of the following nuclear reactions: (a) ${}^{238}_{92}\text{U}(\text{n}, \gamma){}^{239}_{92}\text{U}$, (b) ${}^{14}_7\text{N}(\text{p}, \alpha){}^{11}_6\text{C}$, (c) ${}^{18}_8\text{O}(\text{n}, \beta){}^{19}_9\text{F}$.

RATES OF RADIOACTIVE DECAY (section 21.4)

- 21.31** Each statement that follows refers to a comparison between two radioisotopes, A and X. Indicate whether each of the following statements is true or false, and why.
- (a) If the half-life for A is shorter than the half-life for X, A has a larger decay rate constant.
 (b) If X is "not radioactive," its half-life is essentially zero.
 (c) If A has a half-life of 10 years, and X has a half-life of 10,000 years, A would be a more suitable radioisotope to measure processes occurring on the 40-year time scale.
- 21.32** It has been suggested that strontium-90 (generated by nuclear testing) deposited in the hot desert will undergo radioactive decay more rapidly because it will be exposed to much higher average temperatures. (a) Is this a reasonable suggestion? (b) Does the process of radioactive decay have an activation energy, like the Arrhenius behavior of many chemical reactions (Section 14.5)? Discuss.
- 21.33** Some watch dials are coated with a phosphor, like ZnS, and a polymer in which some of the ${}^1\text{H}$ atoms have been replaced by ${}^3\text{H}$ atoms, tritium. The phosphor emits light when struck by the beta particle from the tritium decay, causing the dials to glow in the dark. The half-life of tritium is 12.3 yr. If the light given off is assumed to be directly proportional to the amount of tritium, by how much will a dial be dimmed in a watch that is 50 years old?

- 21.34** It takes 5.2 min for a 1.000-g sample of ^{210}Fr to decay to 0.250 g. What is the half-life of ^{210}Fr ?
- 21.35** Cobalt-60 is a strong gamma emitter that has a half-life of 5.26 yr. The cobalt-60 in a radiotherapy unit must be replaced when its radioactivity falls to 75% of the original sample. If an original sample was purchased in June 2010, when will it be necessary to replace the cobalt-60?
- 21.36** How much time is required for a 6.25-mg sample of ^{51}Cr to decay to 0.75 mg if it has a half-life of 27.8 days?
- [21.37]** Radium-226, which undergoes alpha decay, has a half-life of 1600 yr. (a) How many alpha particles are emitted in 5.0 min by a 10.0-mg sample of ^{226}Ra ? (b) What is the activity of the sample in mCi?
- [21.38]** Cobalt-60, which undergoes beta decay, has a half-life of 5.26 yr. (a) How many beta particles are emitted in 600 s by a 3.75-mg sample of ^{60}Co ? (b) What is the activity of the sample in Bq?
- 21.39** The cloth shroud from around a mummy is found to have a ^{14}C activity of 9.7 disintegrations per minute per gram of carbon as compared with living organisms that undergo 16.3 disintegrations per minute per gram of carbon. From the half-life for ^{14}C decay, 5715 yr, calculate the age of the shroud.
- 21.40** A wooden artifact from a Chinese temple has a ^{14}C activity of 38.0 counts per minute as compared with an activity of 58.2 counts per minute for a standard of zero age. From the half-life for ^{14}C decay, 5715 yr, determine the age of the artifact.
- 21.41** Potassium-40 decays to argon-40 with a half-life of 1.27×10^9 yr. What is the age of a rock in which the mass ratio of ^{40}Ar to ^{40}K is 4.2?
- 21.42** The half-life for the process $^{238}\text{U} \longrightarrow ^{206}\text{Pb}$ is 4.5×10^9 yr. A mineral sample contains 75.0 mg of ^{238}U and 18.0 mg of ^{206}Pb . What is the age of the mineral?

ENERGY CHANGES (section 21.6)

- 21.43** The thermite reaction, $\text{Fe}_2\text{O}_3(\text{s}) + 2\text{Al}(\text{s}) \longrightarrow 2\text{Fe}(\text{s}) + \text{Al}_2\text{O}_3(\text{s})$, $\Delta H^\circ = -851.5\text{ kJ/mol}$, is one of the most exothermic reactions known. Because the heat released is sufficient to melt the iron product, the reaction is used to weld metal under the ocean. How much heat is released per mole of Fe_2O_3 produced? How does this amount of thermal energy compare with the energy released when 2 mol of protons and 2 mol of neutrons combine to form 1 mol of alpha particles?
- 21.44** An analytical laboratory balance typically measures mass to the nearest 0.1 mg. What energy change would accompany the loss of 0.1 mg in mass?
- 21.45** How much energy must be supplied to break a single aluminum-27 nucleus into separated protons and neutrons if an aluminum-27 atom has a mass of 26.9815386 amu? How much energy is required for 100.0 grams of aluminum-27? (The mass of an electron is given on the inside back cover.)
- 21.46** How much energy must be supplied to break a single ^{21}Ne nucleus into separated protons and neutrons if the nucleus has a mass of 20.98846 amu? What is the nuclear binding energy for 1 mol of ^{21}Ne ?
- 21.47** The atomic masses of hydrogen-2 (deuterium), helium-4, and lithium-6 are 2.014102 amu, 4.002602 amu, and 6.0151228 amu, respectively. For each isotope, calculate (a) the nuclear mass, (b) the nuclear binding energy, (c) the nuclear binding energy per nucleon. (d) Which of these three isotopes has the largest nuclear binding energy per nucleon? Does this agree with the trends plotted in Figure 21.12?
- 21.48** The atomic masses of nitrogen-14, titanium-48, and xenon-129 are 13.999234 amu, 47.935878 amu, and 128.904779 amu, respectively. For each isotope, calculate (a) the nuclear mass, (b) the nuclear binding energy, (c) the nuclear binding energy per nucleon.
- 21.49** The energy from solar radiation falling on Earth is 1.07×10^{16} kJ/min. (a) How much loss of mass from the Sun occurs in one day from just the energy falling on Earth? (b) If the energy released in the reaction
- $$^{235}\text{U} + ^1_0\text{n} \longrightarrow ^{141}_{56}\text{Ba} + ^{92}_{36}\text{Kr} + 3^1_0\text{n}$$
- (^{235}U nuclear mass, 234.9935 amu; ^{141}Ba nuclear mass, 140.8833 amu; ^{92}Kr nuclear mass, 91.9021 amu) is taken as typical of that occurring in a nuclear reactor, what mass of uranium-235 is required to equal 0.10% of the solar energy that falls on Earth in 1.0 day?
- 21.50** Based on the following atomic mass values— ^1H , 1.00782 amu; ^2H , 2.01410 amu; ^3H , 3.01605 amu; ^3He , 3.01603 amu; ^4He , 4.00260 amu—and the mass of the neutron given in the text, calculate the energy released per mole in each of the following nuclear reactions, all of which are possibilities for a controlled fusion process:
- (a) $^2_1\text{H} + ^3_1\text{H} \longrightarrow ^4_2\text{He} + ^1_0\text{n}$
 (b) $^2_1\text{H} + ^2_1\text{H} \longrightarrow ^3_2\text{He} + ^1_0\text{n}$
 (c) $^2_1\text{H} + ^3_2\text{He} \longrightarrow ^4_2\text{He} + ^1_1\text{H}$
- 21.51** Which of the following nuclei is likely to have the largest mass defect per nucleon: (a) ^{59}Co , (b) ^{11}B , (c) ^{118}Sn , (d) ^{243}Cm ? Explain your answer.
- 21.52** The isotope $^{62}_{28}\text{Ni}$ has the largest binding energy per nucleon of any isotope. Calculate this value from the atomic mass of nickel-62 (61.928345 amu) and compare it with the value given for iron-56 in Table 21.7.

EFFECTS AND USES OF RADIOISOTOPES (sections 21.7–21.9)

- 21.53** Iodine-131 is a convenient radioisotope to monitor thyroid activity in humans. It is a beta emitter with a half-life of 8.02 days. The thyroid is the only gland in the body that uses iodine. A person undergoing a test of thyroid activity drinks a solution of NaI, in which only a small fraction of the iodide is radioactive. (a) Why is NaI a good choice for the source of iodine? (b) If a Geiger counter is placed near the person's thyroid (which is near the neck) right after the sodium iodide solution is taken, what will the data look like as a function of time? (c) A normal thyroid will take up about 12% of the ingested iodide in a few hours. How long will it take for the radioactive iodide taken up and held by the thyroid to decay to 0.01% of the original amount?

- 21.54** Why is it important that radioisotopes used as diagnostic tools in nuclear medicine produce gamma radiation when they decay? Why are alpha emitters not used as diagnostic tools?
- 21.55** What is the most common fissionable isotope in a commercial nuclear power reactor?
- 21.56** What is meant by enriched uranium? How is enriched uranium different from natural uranium?
- 21.57** What is the function of the control rods in a nuclear reactor? What substances are used to construct control rods? Why are these substances chosen?
- 21.58** (a) What is the function of the moderator in a nuclear reactor? (b) What substance acts as the moderator in a pressurized water generator? (c) What other substances are used as a moderator in nuclear reactor designs?
- 21.59** Complete and balance the nuclear equations for the following fission or fusion reactions:
 (a) ${}^2_1\text{H} + {}^2_1\text{H} \longrightarrow {}^3_2\text{He} + \underline{\hspace{1cm}}$
 (b) ${}^{239}_{92}\text{U} + {}^1_0\text{n} \longrightarrow {}^{133}_{51}\text{Sb} + {}^{98}_{41}\text{Nb} + \underline{\hspace{1cm}} {}^1_0\text{n}$
- 21.60** Complete and balance the nuclear equations for the following fission reactions:
 (a) ${}^{235}_{92}\text{U} + {}^1_0\text{n} \longrightarrow {}^{160}_{62}\text{Sm} + {}^{72}_{30}\text{Zn} + \underline{\hspace{1cm}} {}^1_0\text{n}$
 (b) ${}^{239}_{94}\text{Pu} + {}^1_0\text{n} \longrightarrow {}^{144}_{58}\text{Ce} + \underline{\hspace{1cm}} + 2{}^1_0\text{n}$
- 21.61** A portion of the Sun's energy comes from the reaction

$$4 {}^1_1\text{H} \longrightarrow {}^4_2\text{He} + 2 {}^0_{-1}\text{e}$$
 which requires a temperature of 10^6 to 10^7 K. (a) Use the mass of the helium-4 nucleus given in Table 21.7 to determine how much energy is released when the reaction is run with 1 mol of hydrogen atoms. (b) Why is such a high temperature required?
- 21.62** The spent fuel elements from a fission reactor are much more intensely radioactive than the original fuel elements. (a) What does this tell you about the products of the fission process in relationship to the belt of stability, Figure 21.2? (b) Given that only two or three neutrons are released per fission event and knowing that the nucleus undergoing fission has a neutron-to-proton ratio characteristic of a heavy nucleus, what sorts of decay would you expect to be dominant among the fission products?
- 21.63** Which type or types of nuclear reactors have these characteristics?
 (a) Does not use a secondary coolant
 (b) Creates more fissionable material than it consumes
 (c) Uses a gas, such as He or CO_2 , as the primary coolant
- 21.64** Which type or types of nuclear reactors have these characteristics?
 (a) Can use natural uranium as a fuel
 (b) Does not use a moderator
 (c) Can be refueled without shutting down
- 21.65** Hydroxyl radicals can pluck hydrogen atoms from molecules ("hydrogen abstraction"), and hydroxide ions can pluck protons from molecules ("deprotonation"). Write the reaction equations and Lewis dot structures for the hydrogen abstraction and deprotonation reactions for the generic carboxylic acid $\text{R}-\text{COOH}$ with hydroxyl radical and hydroxide ion, respectively. Why is hydroxyl radical more toxic to living systems than hydroxide ion?
- 21.66** Which are classified as ionizing radiation: X-rays, alpha particles, microwaves from a cell phone, and gamma rays?
- 21.67** A laboratory rat is exposed to an alpha-radiation source whose activity is 14.3 mCi. (a) What is the activity of the radiation in disintegrations per second? In becquerels? (b) The rat has a mass of 385 g and is exposed to the radiation for 14.0 s, absorbing 35% of the emitted alpha particles, each having an energy of 9.12×10^{-13} J. Calculate the absorbed dose in millirads and grays. (c) If the RBE of the radiation is 9.5, calculate the effective absorbed dose in mrem and Sv.
- 21.68** A 65-kg person is accidentally exposed for 240 s to a 15-mCi source of beta radiation coming from a sample of ${}^{90}\text{Sr}$. (a) What is the activity of the radiation source in disintegrations per second? In becquerels? (b) Each beta particle has an energy of 8.75×10^{-14} J, and 7.5% of the radiation is absorbed by the person. Assuming that the absorbed radiation is spread over the person's entire body, calculate the absorbed dose in rads and in grays. (c) If the RBE of the beta particles is 1.0, what is the effective dose in mrem and in sieverts? (d) How does the magnitude of this dose of radiation compare with that of a mammogram (300 mrem)?

ADDITIONAL EXERCISES

- 21.69** Radon-222 decays to a stable nucleus by a series of three alpha emissions and two beta emissions. What is the stable nucleus that is formed?
- 21.70** Equation 21.28 is the nuclear reaction responsible for much of the helium-4 production in our Sun. How much energy is released in this reaction?
- 21.71** Chlorine has two stable nuclides, ${}^{35}\text{Cl}$ and ${}^{37}\text{Cl}$. In contrast, ${}^{36}\text{Cl}$ is a radioactive nuclide that decays by beta emission. (a) What is the product of decay of ${}^{36}\text{Cl}$? (b) Based on the empirical rules about nuclear stability, explain why the nucleus of ${}^{36}\text{Cl}$ is less stable than either ${}^{35}\text{Cl}$ or ${}^{37}\text{Cl}$.
- 21.72** When two protons fuse in a star, the product is ${}^2_1\text{H}$ plus a positron (Equation 21.26). Why do you think the more obvious product of the reaction, ${}^2_2\text{He}$, is unstable?
- 21.73** Nuclear scientists have synthesized approximately 1600 nuclei not known in nature. More might be discovered with heavy-ion bombardment using high-energy particle accelerators. Complete and balance the following reactions, which involve heavy-ion bombardments:
- (a) ${}^6_3\text{Li} + {}^{56}_{28}\text{Ni} \longrightarrow ?$
 (b) ${}^{40}_{20}\text{Ca} + {}^{248}_{96}\text{Cm} \longrightarrow {}^{147}_{62}\text{Sm} + ?$
 (c) ${}^{88}_{38}\text{Sr} + {}^{84}_{36}\text{Kr} \longrightarrow {}^{116}_{46}\text{Pd} + ?$
 (d) ${}^{40}_{20}\text{Ca} + {}^{238}_{92}\text{U} \longrightarrow {}^{70}_{30}\text{Zn} + 4 {}^1_0\text{n} + 2?$
- [21.74]** The synthetic radioisotope technetium-99, which decays by beta emission, is the most widely used isotope in nuclear medicine. The following data were collected on a sample of ${}^{99}\text{Tc}$:
- | Disintegrations per Minute | Time (h) |
|----------------------------|----------|
| 180 | 0 |
| 130 | 2.5 |
| 104 | 5.0 |
| 77 | 7.5 |
| 59 | 10.0 |
| 46 | 12.5 |
| 24 | 17.5 |
- Using these data, make an appropriate graph and curve fit to determine the half-life.

- [21.75] According to current regulations, the maximum permissible dose of strontium-90 in the body of an adult is $1 \mu\text{Ci}$ (1×10^{-6} Ci). Using the relationship $\text{rate} = kN$, calculate the number of atoms of strontium-90 to which this dose corresponds. To what mass of strontium-90 does this correspond? The half-life for strontium-90 is 28.8 yr.
- [21.76] Suppose you had a detection device that could count every decay event from a radioactive sample of plutonium-239 ($t_{1/2}$ is 24,000 yr). How many counts per second would you obtain from a sample containing 0.385 g of plutonium-239?
- 21.77 Methyl acetate ($\text{CH}_3\text{COOCH}_3$) is formed by the reaction of acetic acid with methyl alcohol. If the methyl alcohol is labeled with oxygen-18, the oxygen-18 ends up in the methyl acetate:

Do the C—OH bond of the acid and the O—H bond of the alcohol break in the reaction, or do the O—H bond of the acid and the C—OH bond of the alcohol break? Explain.

- 21.78 An experiment was designed to determine whether an aquatic plant absorbed iodide ion from water. Iodine-131 ($t_{1/2} = 8.02$ days) was added as a tracer, in the form of iodide ion, to a tank containing the plants. The initial activity of a $1.00\text{-}\mu\text{L}$ sample of the water was 214 counts per minute. After 30 days the level of activity in a $1.00\text{-}\mu\text{L}$ sample was 15.7 counts per minute. Did the plants absorb iodide from the water? Explain.
- 21.79 The nuclear masses of ${}^7\text{Be}$, ${}^9\text{Be}$, and ${}^{10}\text{Be}$ are 7.0147, 9.0100, and 10.0113 amu, respectively. Which of these nuclei has the largest binding energy per nucleon?
- [21.80] A 26.00-g sample of water containing tritium, ${}^3_1\text{H}$, emits 1.50×10^3 beta particles per second. Tritium is a weak beta emitter with a half-life of 12.3 yr. What fraction of all the hydrogen in the water sample is tritium?
- 21.81 The Sun radiates energy into space at the rate of 3.9×10^{26} J/s. (a) Calculate the rate of mass loss from the Sun in kg/s. (b) How does this mass loss arise? (c) It is estimated that the Sun contains 9×10^{56} free protons. How many protons per second are consumed in nuclear reactions in the Sun?
- [21.82] The average energy released in the fission of a single uranium-235 nucleus is about 3×10^{-11} J. If the conversion of this energy to electricity in a nuclear power plant is 40% efficient, what mass of uranium-235 undergoes fission in a year in a plant that produces 1000 megawatts? Recall that a watt is 1 J/s.
- 21.83 Tests on human subjects in Boston in 1965 and 1966, following the era of atomic bomb testing, revealed average quantities of about 2 pCi of plutonium radioactivity in the average person. How many disintegrations per second does this level of activity imply? If each alpha particle deposits 8×10^{-13} J of energy and if the average person weighs 75 kg, calculate the number of rads and rems of radiation in 1 yr from such a level of plutonium.

INTEGRATIVE EXERCISES

21.84 A 53.8-mg sample of sodium perchlorate contains radioactive chlorine-36 (whose atomic mass is 36.0 amu). If 29.6% of the chlorine atoms in the sample are chlorine-36 and the remainder are naturally occurring nonradioactive chlorine atoms, how many disintegrations per second are produced by this sample? The half-life of chlorine-36 is 3.0×10^5 yr.

21.85 Calculate the mass of octane, $C_8H_{18}(l)$, that must be burned in air to evolve the same quantity of energy as produced by the fusion of 1.0 g of hydrogen in the following fusion reaction:

Assume that all the products of the combustion of octane are in their gas phases. Use data from Exercise 21.50, Appendix C, and the inside covers of the text. The standard enthalpy of formation of octane is -250.1 kJ/mol.

21.86 A sample of an alpha emitter having an activity of 0.18i is stored in a 25.0-mL sealed container at 22 °C for 245 days. (a) How many alpha particles are formed during this time? (b) Assuming that each alpha particle is converted to a helium atom, what is the partial pressure of helium gas in the container after this 245-day period?

[21.87] Charcoal samples from Stonehenge in England were burned in O_2 , and the resultant CO_2 gas bubbled into a solution of $Ca(OH)_2$ (limewater), resulting in the precipitation of $CaCO_3$. The $CaCO_3$ was removed by filtration and dried. A 788-mg sample of the $CaCO_3$ had a radioactivity of 1.5×10^{-2} Bq due to carbon-14. By comparison, living organisms undergo 15.3 disintegrations per minute per gram of carbon. Using the half-life of carbon-14, 5715 yr, calculate the age of the charcoal sample.

21.88 A 25.0-mL sample of 0.050 M barium nitrate solution was mixed with 25.0 mL of 0.050 M sodium sulfate solution labeled with radioactive sulfur-35. The activity of the initial sodium sulfate solution was 1.22×10^6 Bq/mL. After the resultant precipitate was removed by filtration, the remaining filtrate was found to have an activity of 250 Bq/mL. (a) Write a balanced chemical equation for the reaction that occurred. (b) Calculate the K_{sp} for the precipitate under the conditions of the experiment.

WHAT'S AHEAD

22.1 PERIODIC TRENDS AND CHEMICAL REACTIONS

We begin with a review of periodic trends and types of chemical reactions, which will help us focus on general patterns of behavior as we examine each family in the periodic table.

22.2 HYDROGEN

The first nonmetal we consider, hydrogen, forms compounds with most other nonmetals and with many metals.

22.3 GROUP 8A: THE NOBLE GASES

Next, we consider the noble gases, the elements of group 8A, which exhibit very limited chemical reactivity.

22.4 GROUP 7A: THE HALOGENS

We then explore the most electronegative elements: the halogens, group 7A.

22.5 OXYGEN

We next consider oxygen, the most abundant element by mass in both Earth's crust and the human body, and the oxide and peroxide compounds it forms.

22.6 THE OTHER GROUP 6A ELEMENTS: S, Se, Te, AND Po

We study the other members of group 6A (S, Se, Te, and Po), of which sulfur is the most important.

**AN OCEAN SUNSET SEEN
THROUGH** a glass window.

22.7 NITROGEN

We next consider nitrogen, a key component of our atmosphere. It forms compounds in which its oxidation number ranges from -3 to $+5$, including such important compounds as NH_3 and HNO_3 .

22.8 THE OTHER GROUP 5A ELEMENTS: P, As, Sb, AND Bi

Of the other members of group 5A (P, As, Sb, and Bi), we take a closer look at phosphorus—the most commercially important one and the only one that plays an important and beneficial role in biological systems.

22.9 CARBON

We next focus on the inorganic compounds of carbon.

22.10 THE OTHER GROUP 4A ELEMENTS: Si, Ge, Sn, AND Pb

We then consider silicon, the element most abundant and significant of the heavier members of group 4A.

22.11 BORON

Finally, we examine boron—the sole nonmetallic element of group 3A.

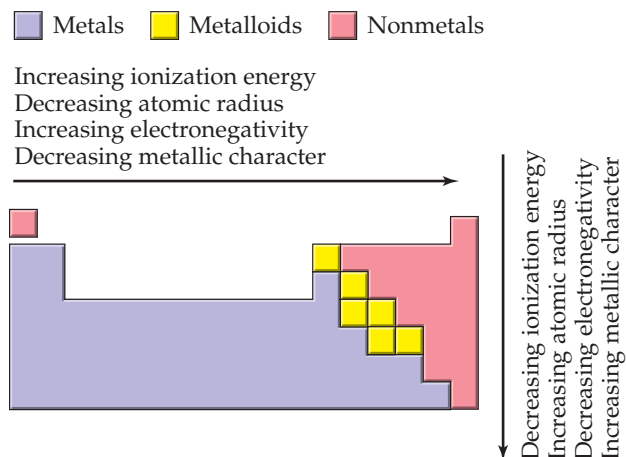

CHEMISTRY OF THE NONMETALS

THE CHAPTER-OPENING PHOTOGRAPH shows the sun setting over the ocean, viewed through a window. Everything we see there comes from nonmetallic elements. The heat and light of the Sun result from the nuclear reactions of hydrogen. We know that water is H_2O ; glass, too, is nonmetallic, being based on silicon dioxide, SiO_2 .

In this chapter we take a panoramic view of the descriptive chemistry of the nonmetallic elements, starting with hydrogen and progressing group by group across the periodic table. We will consider how the elements occur in nature, how they are isolated from their sources, and how they are used. We will emphasize hydrogen, oxygen, nitrogen, and carbon because these four nonmetals form many commercially important compounds and account for 99% of the atoms required by living cells.

As you study this *descriptive chemistry*, it is important to look for trends rather than trying to memorize all the facts presented. The periodic table is your most valuable tool in this task.

22.1 PERIODIC TRENDS AND CHEMICAL REACTIONS

▲ FIGURE 22.1 Trends in elemental properties.

Recall that we can classify elements as metals, metalloids, and nonmetals. ∞ (Section 7.6) Except for hydrogen, which is a special case, the nonmetals occupy the upper right portion of the periodic table. This division of elements relates nicely to trends in the properties of the elements as summarized in ◀ FIGURE 22.1. Electronegativity, for example, increases as we move left to right across a period and decreases as we move down a group. The nonmetals thus have higher electronegativities than the metals. This difference leads to the formation of ionic solids in reactions between metals and nonmetals. ∞ (Sections 7.6, 8.2, 8.4) In contrast, compounds formed between two or more nonmetals are usually molecular substances. ∞ (Sections 7.8 and 8.4)

The chemistry exhibited by the first member of a nonmetal group can differ from that of subsequent members. For example, nonmetals in period 3 and below can accommodate a larger number of bonded neighbors. ∞ (Section 8.7) Another important difference is that the first element in any group can more readily form π bonds. This trend is due, in part, to size because small atoms are able to approach each other more closely. As a result, the overlap of p orbitals, which results in the formation of π bonds, is more effective for the first element in each group (▼ FIGURE 22.2). More effective overlap means stronger π bonds, reflected in bond enthalpies. ∞ (Section 8.8) For example, the difference between the enthalpies of the C—C bond and the C=C bond is about 270 kJ/mol; ∞ (Table 8.4) this value reflects the “strength” of a carbon–carbon π bond, and the difference between Si—Si and Si=Si bonds is only about 100 kJ/mol, significantly lower than that for carbon.

As we shall see, π bonds are particularly important in the chemistry of carbon, nitrogen, and oxygen, each the first member in its group. The heavier elements in these groups have a tendency to form only single bonds.

SAMPLE EXERCISE 22.1 Identifying Elemental Properties

Of the elements Li, K, N, P, and Ne, which (a) is the most electronegative, (b) has the greatest metallic character, (c) can bond to more than four atoms in a molecule, (d) forms π bonds most readily?

SOLUTION

Analyze We are given a list of elements and asked to predict several properties that can be related to periodic trends.

Plan We can use Figures 22.1 and 22.2 to guide us to the answers.

Solve

(a) Electronegativity increases as we proceed toward the upper right portion of the periodic table, excluding the noble gases. Thus, N is the most electronegative element of our choices.

(b) Metallic character correlates inversely with electronegativity—the less electronegative an element, the greater its metallic character. The element with the greatest metallic character is therefore K, which is closest to the lower left corner of the periodic table.

(c) Nonmetals tend to form molecular compounds, so we can narrow our choice to the three nonmetals on the list: N, P, and Ne. To form more than four bonds, an element must be able to expand its valence shell to allow more than an octet of electrons around it. Valence-shell expansion occurs for period 3 elements and below; N and Ne are both in period 2 and do not undergo valence-shell expansion. Thus, the answer is P.

(d) Period 2 nonmetals form π bonds more readily than elements in period 3 and below. There are no compounds known that contain covalent bonds to Ne. Thus, N is the element from the list that forms π bonds most readily.

▲ FIGURE 22.2 π bonds in period 2 and period 3 elements.

PRACTICE EXERCISE

Of the elements Be, C, Cl, Sb, and Cs, which (a) has the lowest electronegativity, (b) has the greatest nonmetallic character, (c) is most likely to participate in extensive π bonding, (d) is most likely to be a metalloid?

Answers: (a) Cs, (b) Cl, (c) C, (d) Sb

The ready ability of period 2 elements to form π bonds is an important factor in determining the structures of these elements and their compounds. Compare, for example, the elemental forms of carbon and silicon. Carbon has five major crystalline allotropes: diamond, graphite, buckminsterfullerene, graphene, and carbon nanotubes. ∞ (Sections 12.7, 12.9) Diamond is a covalent-network solid that has C—C σ bonds but no π bonds. Graphite, buckminsterfullerene, graphene, and carbon nanotubes have π bonds that result from the sideways overlap of p orbitals. Elemental silicon, however, exists only as a diamondlike covalent-network solid with σ bonds; it has no forms analogous to graphite, buckminsterfullerene, graphene, or carbon nanotubes, apparently because Si—Si π bonds are weak.

GIVE IT SOME THOUGHT

Can silicon–silicon double bonds form in elemental silicon?

We likewise see significant differences in the dioxides of carbon and silicon (► **FIGURE 22.3**). CO_2 is a molecular substance containing C=O double bonds, whereas SiO_2 is a covalent-network solid in which four oxygen atoms are bonded to each silicon atom by single bonds, forming an extended structure that has the empirical formula SiO_2 .

GIVE IT SOME THOUGHT

Nitrogen is found in nature as $\text{N}_2(g)$. Would you expect phosphorus to be found in nature as $\text{P}_2(g)$? Explain.

Chemical Reactions

Because O_2 and H_2O are abundant in our environment, it is particularly important to consider how these substances react with other compounds. About one-third of the reactions discussed in this chapter involve either O_2 (oxidation or combustion reactions) or H_2O (especially proton-transfer reactions).

In combustion reactions, ∞ (Section 3.2) hydrogen-containing compounds produce H_2O . Carbon-containing ones produce CO_2 (unless the amount of O_2 is insufficient, in which case CO or even C can form). Nitrogen-containing compounds tend to form N_2 , although NO can form in special cases or in small amounts. A reaction illustrating these points is:

The formation of H_2O , CO_2 , and N_2 reflects the high thermodynamic stability of these substances, indicated by the large bond energies for the O—H, C=O, and $\text{N}\equiv\text{N}$ bonds (463, 799, and 941 kJ/mol, respectively). ∞ (Section 8.8)

When dealing with proton-transfer reactions, remember that the weaker a Brønsted–Lowry acid, the stronger its conjugate base. ∞ (Section 16.2) For example, H_2 , OH^- , NH_3 , and CH_4 are exceedingly weak proton donors that have *no* tendency to act as acids in water. Thus, the species formed by removing one or more protons from them are extremely strong bases. All react readily with water, removing protons from H_2O to form OH^- . Two representative reactions are:

Fragment of extended SiO_2 lattice; Si forms only single bonds

CO_2 ; C forms double bonds

▲ **FIGURE 22.3** Comparison of the bonds in SiO_2 and CO_2 .

SAMPLE EXERCISE 22.2 Predicting the Products of Chemical Reactions

Predict the products formed in each of the following reactions, and write a balanced equation:

**SOLUTION**

Analyze: We are given the reactants for two chemical equations and asked to predict the products and then balance the equations.

Plan We need to examine the reactants to see if we might recognize a reaction type. In (a) the carbon compound is reacting with O_2 , which suggests a combustion reaction. In (b) water reacts with an ionic compound. The anion, P^{3-} , is a strong base and H_2O is able to act as an acid, so the reactants suggest an acid–base (proton-transfer) reaction.

Solve

(a) Based on the elemental composition of the carbon compound, this combustion reaction should produce CO_2 , H_2O , and N_2 :

(b) Mg_3P_2 is ionic, consisting of Mg^{2+} and P^{3-} ions. The P^{3-} ion, like N^{3-} , has a strong affinity for protons and reacts with H_2O to form OH^- and PH_3 (PH_2^- , PH_2^- , and PH_3 are all exceedingly weak proton donors).

$\text{Mg}(\text{OH})_2$ has low solubility in water and will precipitate.

PRACTICE EXERCISE

Write a balanced equation for the reaction of solid sodium hydride with water.

Answer: $\text{NaH}(\text{s}) + \text{H}_2\text{O}(\text{l}) \longrightarrow \text{NaOH}(\text{aq}) + \text{H}_2(\text{g})$

22.2 | HYDROGEN

The English chemist Henry Cavendish (1731–1810) was the first to isolate hydrogen. Because the element produces water when burned in air, the French chemist Antoine Lavoisier ∞ (Figure 3.1) gave it the name *hydrogen*, which means “water producer” (Greek: *hydro*, water; *gennaō*, to produce).

Hydrogen is the most abundant element in the universe. It is the nuclear fuel consumed by our Sun and other stars to produce energy. ∞ (Section 21.8) Although about 75% of the known mass of the universe is hydrogen, it constitutes only 0.87% of Earth’s mass. Most of the hydrogen on our planet is found associated with oxygen. Water, which is 11% hydrogen by mass, is the most abundant hydrogen compound.

Isotopes of Hydrogen

The most common isotope of hydrogen, ${}^1_1\text{H}$, has a nucleus consisting of a single proton. This isotope, sometimes referred to as **protium**,* makes up 99.9844% of naturally occurring hydrogen.

Two other isotopes are known: ${}^2_1\text{H}$, whose nucleus contains a proton and a neutron, and ${}^3_1\text{H}$, whose nucleus contains a proton and two neutrons. The ${}^2_1\text{H}$ isotope, **deuterium**, makes up 0.0156% of naturally occurring hydrogen. It is not radioactive and is often given the symbol D in chemical formulas, as in D_2O (deuterium oxide), which is known as *heavy water*.

Because an atom of deuterium is about twice as massive as an atom of protium, the properties of deuterium-containing substances vary somewhat from those of the protium-containing analogs. For example, the normal melting and boiling points of D_2O are 3.81 °C and 101.42 °C, respectively, versus 0.00 °C and 100.00 °C for H_2O . Not surprisingly, the

*Giving unique names to isotopes is limited to hydrogen. Because of the proportionally large differences in their masses, the isotopes of H show appreciably more differences in their properties than isotopes of heavier elements.

density of D₂O at 25 °C (1.104 g/mL) is greater than that of H₂O (0.997 g/mL). Replacing protium with deuterium (a process called *deuteration*) can also have a profound effect on reaction rates, a phenomenon called a *kinetic-isotope effect*. For example, heavy water can be obtained from the electrolysis [2 H₂O(l) → 2 H₂(g) + O₂(g)] of ordinary water because the small amount of naturally occurring D₂O in the sample undergoes electrolysis more slowly than H₂O and, therefore, becomes concentrated during the reaction.

The third isotope, ³H, **tritium**, is radioactive, with a half-life of 12.3 yr:

Because of its short half-life, only trace quantities of tritium exist naturally. The isotope can be synthesized in nuclear reactors by neutron bombardment of lithium-6:

Deuterium and tritium are useful in studying reactions of compounds containing hydrogen. A compound is “labeled” by replacing one or more ordinary hydrogen atoms with deuterium or tritium at specific locations in a molecule. By comparing the locations of the label atoms in reactants and products, the reaction mechanism can often be inferred. When methyl alcohol (CH₃OH) is placed in D₂O, for example, the H atom of the O—H bond exchanges rapidly with the D atoms, forming CH₃OD. The H atoms of the CH₃ group do not exchange. This experiment demonstrates the kinetic stability of C—H bonds and reveals the speed at which the O—H bond in the molecule breaks and re-forms.

Properties of Hydrogen

Hydrogen is the only element that is not a member of any family in the periodic table. Because of its 1s¹ electron configuration, it is generally placed above lithium in the table. However, it is definitely *not* an alkali metal. It forms a positive ion much less readily than any alkali metal. The ionization energy of the hydrogen atom is 1312 kJ/mol, whereas that of lithium is 520 kJ/mol.

Hydrogen is sometimes placed above the halogens in the periodic table because the hydrogen atom can pick up one electron to form the *hydride ion*, H[−], which has the same electron configuration as helium. However, the electron affinity of hydrogen, $E = -73 \text{ kJ/mol}$, is not as large as that of any halogen. In general, hydrogen shows no closer resemblance to the halogens than it does to the alkali metals.

Elemental hydrogen exists at room temperature as a colorless, odorless, tasteless gas composed of diatomic molecules. We can call H₂ *dihydrogen*, but it is more commonly referred to as either *molecular hydrogen* or simply hydrogen. Because H₂ is nonpolar and has only two electrons, attractive forces between molecules are extremely weak. As a result, its melting point (−259 °C) and boiling point (−253 °C) are very low.

The H—H bond enthalpy (436 kJ/mol) is high for a single bond. ∞ (Table 8.4) By comparison, the Cl—Cl bond enthalpy is only 242 kJ/mol. Because H₂ has a strong bond, most reactions involving H₂ are slow at room temperature. However, the molecule is readily activated by heat, irradiation, or catalysis. The activation generally produces hydrogen atoms, which are very reactive. Once H₂ is activated, it reacts rapidly and exothermically with a wide variety of substances.

GIVE IT SOME THOUGHT

If H₂ is activated to produce H⁺, what must the other product be?

Hydrogen forms strong covalent bonds with many other elements, including oxygen; the O—H bond enthalpy is 463 kJ/mol. The formation of the strong O—H bond makes hydrogen an effective reducing agent for many metal oxides. When H₂ is passed over heated CuO, for example, copper is produced:

When H_2 is ignited in air, a vigorous reaction occurs, forming H_2O . Air containing as little as 4% H_2 by volume is potentially explosive. Combustion of hydrogen-oxygen mixtures is used in liquid-fuel rocket engines such as those of the Space Shuttle. The hydrogen and oxygen are stored at low temperatures in liquid form.

Production of Hydrogen

When a small quantity of H_2 is needed in the laboratory, it is usually obtained by the reaction between an active metal such as zinc and a dilute strong acid such as HCl or H_2SO_4 :

Large quantities of H_2 are produced by reacting methane with steam at 1100°C . We can view this process as involving two reactions:

Carbon heated with water to about 1000°C is another source of H_2 :

This mixture, known as *water gas*, is used as an industrial fuel.

A CLOSER LOOK

THE HYDROGEN ECONOMY

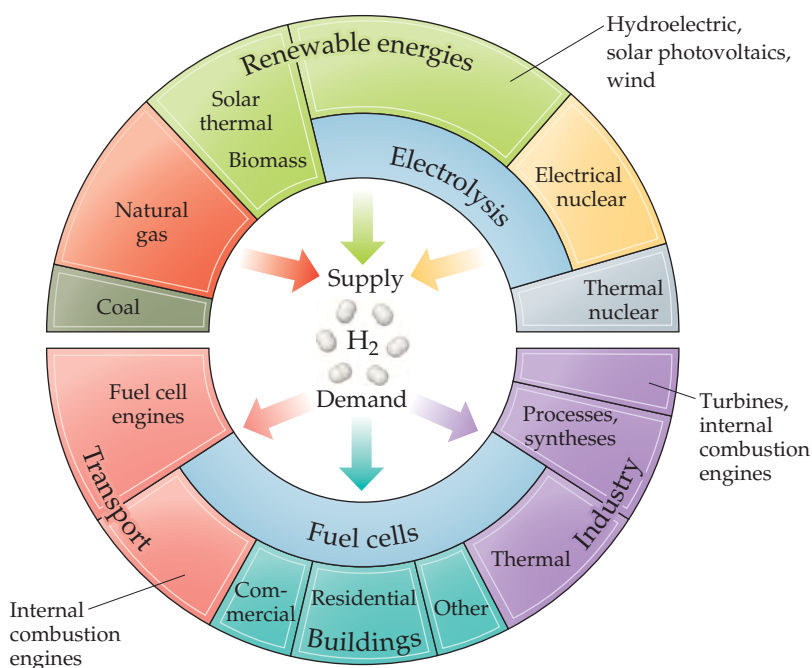

The reaction of hydrogen with oxygen is highly exothermic:

Because the only product of the reaction is water vapor, the prospect of using hydrogen as a fuel in fuel cells is attractive. (Section 20.7) Alternatively, hydrogen could be combusted directly with oxygen from the atmosphere in an internal combustion engine. In either case, it would be necessary to generate elemental hydrogen on a large scale and arrange for its transport and storage.

▼ FIGURE 22.4 illustrates various sources and uses of H_2 fuel. The generation of H_2 through electrolysis of water is in principle the cleanest route, because this process—the reverse of Equation 22.11—produces only hydrogen and oxygen. (Figure 1.7 and Section 20.9) However, the energy required to electrolyze water must come from somewhere. If we burn fossil fuels to generate this energy, we have not advanced very far toward a true hydrogen economy. If the energy for electrolysis came instead from a hydroelectric or nuclear power plant, solar cells, or wind generators, consumption of nonrenewable energy sources and undesired production of CO_2 could be avoided.

RELATED EXERCISES: 22.29, 22.30, 22.91

◀ FIGURE 22.4 The “hydrogen economy” would require hydrogen to be produced from various sources and would use hydrogen in energy-related applications.

Electrolysis of water consumes too much energy and is consequently too costly to be used commercially to produce H_2 . However, H_2 is produced as a by-product in the electrolysis of brine (NaCl) solutions in the course of commercial Cl_2 and NaOH manufacture:

GIVE IT SOME THOUGHT

What are the oxidation states of the H atoms in Equations 22.7–22.12?

Uses of Hydrogen

Hydrogen is commercially important. About 5.0×10^{10} kg (50 million metric tons) is produced annually across the world. About half of the H_2 produced is used to synthesize ammonia by the Haber process. ∞ (Section 15.2) Much of the remaining hydrogen is used to convert high-molecular-weight hydrocarbons from petroleum into lower-molecular-weight hydrocarbons suitable for fuel (gasoline, diesel, and others) in a process known as *cracking*. Hydrogen is also used to manufacture methanol via the catalytic reaction of CO and H_2 at high pressure and temperature:

Binary Hydrogen Compounds

Hydrogen reacts with other elements to form three types of compounds: (1) ionic hydrides, (2) metallic hydrides, and (3) molecular hydrides.

The **ionic hydrides** are formed by the alkali metals and by the heavier alkaline earths (Ca, Sr, and Ba). These active metals are much less electronegative than hydrogen. Consequently, hydrogen acquires electrons from them to form hydride ions (H^-):

The hydride ion is very basic and reacts readily with compounds having even weakly acidic protons to form H_2 :

Ionic hydrides can therefore be used as convenient (although expensive) sources of H_2 .

Calcium hydride (CaH_2) is used to inflate life rafts, weather balloons, and the like where a simple, compact means of generating H_2 is desired (\blacktriangledown FIGURE 22.5).

GO FIGURE

This reaction is exothermic. Is the beaker on the right warmer or colder than the beaker on the left?

◀ FIGURE 22.5 The reaction of CaH_2 with water.

The reaction between H^- and H_2O (Equation 22.15) is an acid–base reaction *and* a redox reaction. The H^- ion, therefore, is a good base *and* a good reducing agent. In fact, hydrides are able to reduce O_2 to OH^- :

For this reason, hydrides are normally stored in an environment that is free of both moisture and air.

Metallic hydrides are formed when hydrogen reacts with transition metals. These compounds are so named because they retain their metallic properties. They are not molecular substances, just as metals are not. In many metallic hydrides, the ratio of metal atoms to hydrogen atoms is not fixed or in small whole numbers. The composition can vary within a range, depending on reaction conditions. TiH_2 can be produced, for example, but preparations usually yield $\text{TiH}_{1.8}$. These nonstoichiometric metallic hydrides are sometimes called *interstitial hydrides*. Because hydrogen atoms are small enough to fit between the sites occupied by the metal atoms, many metal hydrides behave like interstitial alloys. ∞ (Section 12.3)

The most interesting interstitial metallic hydride is that of palladium. Palladium can take up nearly 900 times its volume of hydrogen, making it very attractive for hydrogen storage in any possible future “hydrogen economy.” However, to be practical, any hydrogen-storage compound will have to contain 75% or more hydrogen by mass and be able to charge and discharge hydrogen quickly and safely near room temperature.

GIVE IT SOME THOUGHT

Palladium has a density of 12.023 g/cm^3 . Can a sample of Pd that has a volume of 1 cm^3 increase its mass to over 900 g by adsorbing hydrogen?

The **molecular hydrides**, formed by nonmetals and metalloids, are either gases or liquids under standard conditions. The simple molecular hydrides are listed in **FIGURE 22.6**, together with their standard free energies of formation, ΔG_f° . ∞ (Section 19.5) In each family the thermal stability (measured as ΔG_f°) decreases as we move down the family. (Recall that the more stable a compound is with respect to its elements under standard conditions, the more negative ΔG_f° is.)

▲ FIGURE 22.6 Standard free energies of formation of molecular hydrides. All values are kilojoules per mole of hydride.

22.3 GROUP 8A: THE NOBLE GASES

The elements of group 8A are chemically unreactive. Indeed, most of our references to these elements have been in relation to their physical properties, as when we discussed intermolecular forces. ∞ (Section 11.2) The relative inertness of these elements is due to the presence of a completed octet of valence-shell electrons (except He, which only has a filled $1s$ shell). The stability of such an arrangement is reflected in the high ionization energies of the group 8A elements. ∞ (Section 7.4)

The group 8A elements are all gases at room temperature. They are components of Earth’s atmosphere, except for radon, which exists only as a short-lived radioisotope. ∞ (Section 21.9) Only argon is relatively abundant. ∞ (Table 18.1) Neon, argon, krypton, and xenon are recovered from liquid air by distillation. All four of these noble gases are used in lighting, display, and laser applications in which the atoms are excited electrically and electrons that are in a higher energy state emit light as they fall to the ground state. ∞ (Section 6.2) Argon is used as a blanketing atmosphere in electric lightbulbs. The gas conducts heat away from the filament but does not react with it. Argon is also used as a protective atmosphere to prevent oxidation in welding and certain high-temperature metallurgical processes.

Helium is in many ways the most important noble gas. Liquid helium is used as a coolant to conduct experiments at very low temperatures. Helium boils at 4.2 K and 1 atm, the lowest boiling point of any substance. It is found in relatively high concentrations in many natural-gas wells and can be obtained from them.

86 Rn

Noble-Gas Compounds

Because the noble gases are exceedingly stable, they react only under rigorous conditions. We expect the heavier ones to be most likely to form compounds because their ionization energies are lower. ∞ (Figure 7.9) A lower ionization energy suggests the possibility of sharing an electron with another atom, leading to a chemical bond. In addition, because the group 8A elements (except helium) already contain eight electrons in their valence shell, formation of covalent bonds will require an expanded valence shell. Valence-shell expansion occurs most readily with larger atoms. ∞ (Section 8.7)

The first noble-gas compound was reported in 1962. This discovery caused a sensation because it undercut the belief that the noble-gas elements were inert. The initial study involved xenon in combination with fluorine, the element we would expect to be most reactive in pulling electron density from another atom. Since that time chemists have prepared several xenon compounds of fluorine and oxygen (▼ TABLE 22.1). The fluorides XeF_2 , XeF_4 , and XeF_6 are made by direct reaction of the elements. By varying the ratio of reactants and altering reaction conditions, one of the three compounds can be obtained. The oxygen-containing compounds are formed when the fluorides react with water as, for example,

SAMPLE EXERCISE 22.3 Predicting a Molecular Structure

Use the VSEPR model to predict the structure of XeF_4 .

SOLUTION

Analyze We must predict the geometrical structure given only the molecular formula.

Plan We must first write the Lewis structure for the molecule. We then count the number of electron pairs (domains) around the Xe atom and use that number and the number of bonds to predict the geometry.

Solve There are 36 valence-shell electrons (8 from xenon and 7 from each fluorine). If we make four single Xe—F bonds, each fluorine has its octet satisfied. Xe then has 12 electrons in its valence shell, so we expect an octahedral arrangement of six electron pairs. Two of these are nonbonded pairs. Because nonbonded pairs require more volume than bonded pairs ∞ (Section 9.2), it is reasonable to expect these nonbonded pairs to be opposite each other. The expected structure is square planar, as shown in ► FIGURE 22.7.

Comment The experimentally determined structure agrees with this prediction.

PRACTICE EXERCISE

Describe the electron-domain geometry and molecular geometry of XeF_2 .

Answer: trigonal bipyramidal, linear

▲ FIGURE 22.7 Xenon tetrafluoride.

The other noble-gas elements form compounds much less readily than xenon. For many years, only one binary krypton compound, KrF_2 , was known with certainty, and it decomposes to its elements at -10°C . Other compounds of krypton have been isolated at very low temperatures (40 K).

TABLE 22.1 • Properties of Xenon Compounds

22.4 GROUP 7A: THE HALOGENS

7A
9 F
17 Cl
35 Br
53 I
85 At

The elements of group 7A, the halogens, have the outer-electron configuration ns^2np^5 , where n ranges from 2 through 6. The halogens have large negative electron affinities ∞ (Section 7.5), and they most often achieve a noble-gas configuration by gaining an electron, which results in a -1 oxidation state. Fluorine, being the most electronegative element, exists in compounds only in the -1 state. The other halogens exhibit positive oxidation states up to $+7$ in combination with more electronegative atoms such as O. In the positive oxidation states, the halogens tend to be good oxidizing agents, readily accepting electrons.

Chlorine, bromine, and iodine are found as the halides in seawater and in salt deposits. Fluorine occurs in the minerals fluor spar (CaF_2), cryolite (Na_3AlF_6), and fluorapatite [$\text{Ca}_5(\text{PO}_4)_3\text{F}$].* Only fluor spar is an important commercial source of fluorine.

All isotopes of astatine are radioactive. The longest-lived isotope is astatine-210, which has a half-life of 8.1 hr and decays mainly by electron capture. Because astatine is so unstable, very little is known about its chemistry.

GO FIGURE

Do Br_2 and I_2 appear to be more or less soluble in CCl_4 than in H_2O ?

▲ FIGURE 22.8 Reaction of Cl_2 with aqueous solutions of NaF , NaBr , and NaI . The top liquid layer is water; the bottom liquid layer is carbon tetrachloride.

Properties and Production of the Halogens

Most properties of the halogens vary in a regular fashion as we go from fluorine to iodine (▼ TABLE 22.2).

Under ordinary conditions the halogens exist as diatomic molecules. The molecules are held together in the solid and liquid states by dispersion forces. ∞ (Section 11.2) Because I_2 is the largest and most polarizable halogen molecule, the intermolecular forces between I_2 molecules are the strongest. Thus, I_2 has the highest melting point and boiling point. At room temperature and 1 atm, I_2 is a purple solid, Br_2 is a red-brown liquid, and Cl_2 and F_2 are gases. ∞ (Figure 7.27) Chlorine readily liquefies upon compression at room temperature and is normally stored and handled in liquid form under pressure in steel containers.

The comparatively low bond enthalpy of F_2 (155 kJ/mol) accounts in part for the extreme reactivity of elemental fluorine. Because of its high reactivity, F_2 is difficult to work with. Certain metals, such as copper and nickel, can be used to contain F_2 because their surfaces form a protective coating of metal fluoride. Chlorine and the heavier halogens are also reactive, although less so than fluorine.

Because of their high electronegativities, the halogens tend to gain electrons from other substances and thereby serve as oxidizing agents. The oxidizing ability of the halogens, indicated by their standard reduction potentials, decreases going down the group. As a result, a given halogen is able to oxidize the halide anions below it. For example, Cl_2 oxidizes Br^- and I^- but not F^- , as seen in ◀ FIGURE 22.8.

TABLE 22.2 • Some Properties of the Halogens

Property	F	Cl	Br	I
Atomic radius (Å)	0.71	0.99	1.14	1.33
Ionic radius, X^- (Å)	1.33	1.81	1.96	2.20

Reduction potential (V): $\frac{1}{2} \text{X}_2(\text{aq}) + \text{e}^- \longrightarrow \text{X}^-(\text{aq})$	2.87	1.36	1.07	0.54

*Minerals are solid substances that occur in nature. They are usually known by their common names rather than by their chemical names. What we know as rock is merely an aggregate of different minerals.

SAMPLE EXERCISE 22.4 Predicting Chemical Reactions among the Halogens

Write the balanced equation for the reaction, if any, between (a) $\text{I}^-(aq)$ and $\text{Br}_2(l)$, (b) $\text{Cl}^-(aq)$ and $\text{I}_2(s)$.

SOLUTION

Analyze We are asked to determine whether a reaction occurs when a particular halide and halogen are combined.

Plan A given halogen is able to oxidize anions of the halogens below it in the periodic table. Thus, in each pair the halogen having the smaller atomic number ends up as the halide ion. If the halogen with the smaller atomic number is already the halide, there is no reaction. Thus, the key to determining whether a reaction occurs is locating the elements in the periodic table.

Solve

(a) Br_2 can oxidize (remove electrons from) the anions of the halogens below it in the periodic table. Thus, it oxidizes I^- :

(b) Cl^- is the anion of a halogen above iodine in the periodic table. Thus, I_2 cannot oxidize Cl^- ; there is no reaction.

PRACTICE EXERCISE

Write the balanced chemical equation for the reaction between $\text{Br}^-(aq)$ and $\text{Cl}_2(aq)$.

Answer: $2 \text{Br}^-(aq) + \text{Cl}_2(aq) \longrightarrow \text{Br}_2(aq) + 2 \text{Cl}^-(aq)$

Notice in Table 22.2 that the standard reduction potential of F_2 is exceptionally high. Fluorine gas readily oxidizes water:

Fluorine cannot be prepared by electrolytic oxidation of aqueous solutions of fluoride salts because water is oxidized more readily than F^- . ∞ (Section 20.9) In practice, the element is formed by electrolytic oxidation of a solution of KF in anhydrous HF .

Chlorine is produced mainly by electrolysis of either molten or aqueous sodium chloride. Both bromine and iodine are obtained commercially from brines containing the halide ions; the reaction used is oxidation with Cl_2 .

Uses of the Halogens

Fluorine is used to prepare fluorocarbons—very stable carbon–fluorine compounds used as refrigerants, lubricants, and plastics. Teflon® (► FIGURE 22.9) is a polymeric fluorocarbon noted for its high thermal stability and lack of chemical reactivity.

Chlorine is by far the most commercially important halogen. About 1×10^{10} kg (10 million tons) of Cl_2 is produced annually in the United States. In addition, hydrogen chloride production is about 4.0×10^9 kg (4.4 million tons) annually. About half of this chlorine finds its way eventually into the manufacture of chlorine-containing organic compounds, such as the vinyl chloride ($\text{C}_2\text{H}_3\text{Cl}$) used in making polyvinyl chloride (PVC) plastics. ∞ (Section 12.8) Much of the remainder is used as a bleaching agent in the paper and textile industries. When Cl_2 dissolves in cold dilute base, it converts into Cl^- and hypochlorite, ClO^- :

**GIVE IT SOME THOUGHT**

What is the oxidation state of Cl in each Cl species in Equation 22.19?

Sodium hypochlorite (NaClO) is the active ingredient in many liquid bleaches. Chlorine is also used in water treatment to oxidize and thereby destroy bacteria. ∞ (Section 18.4)

A common use of iodine is as KI in table salt. Iodized salt provides the small amount of iodine necessary in our diets; it is essential for the formation of thyroxine, a hormone secreted by the thyroid gland. Lack of iodine in the diet results in an enlarged thyroid gland, a condition called *goiter*.

The Hydrogen Halides

All the halogens form stable diatomic molecules with hydrogen. Aqueous solutions of HCl, HBr, and HI are strong acids. The hydrogen halides can be formed by direct reaction of the elements. The most important means of preparing HF and HCl, however, is by reacting a salt of the halide with a strong nonvolatile acid, as in the reaction

Neither HBr nor HI can be prepared in this way, however, because H_2SO_4 oxidizes Br^- and I^- (▼ FIGURE 22.10). This difference in reactivity reflects the greater ease of oxidation of Br^- and I^- relative to F^- and Cl^- . These undesirable oxidations are avoided by using a nonvolatile acid, such as H_3PO_4 , that is a weaker oxidizing agent than H_2SO_4 .

SAMPLE EXERCISE 22.5 Writing a Balanced Chemical Equation

Write a balanced equation for the formation of hydrogen bromide gas from the reaction of solid sodium bromide with phosphoric acid.

SOLUTION

Analyze We are asked to write a balanced equation for the reaction between NaBr and H_3PO_4 to form HBr and another product.

Plan As in Equation 22.20, a metathesis reaction takes place. ∞∞ (Section 4.2) Let's assume that only one H in H_3PO_4 reacts. (The actual number depends on the reaction conditions.) The H_2PO_4^- and Na^+ will form NaH_2PO_4 as one product.

Solve The balanced equation is

PRACTICE EXERCISE

Write the balanced equation for the preparation of HI from NaI and H_3PO_4 .

Answer: $\text{NaI}(\text{s}) + \text{H}_3\text{PO}_4(\text{l}) \longrightarrow \text{NaH}_2\text{PO}_4(\text{s}) + \text{HI}(\text{g})$

GO FIGURE

Are these reactions acid–base reactions or oxidation–reduction reactions?

► FIGURE 22.10 Reaction of H_2SO_4 with NaI and NaBr.

TABLE 22.3 • The Stable Oxyacids of the Halogens

Oxidation State of Halogen	Formula of Acid			Acid Name
	Cl	Br	I	
+1	HClO	HBrO	HIO	<i>Hypohalous acid</i>
+3	HClO ₂	—	—	<i>Halous acid</i>
+5	HClO ₃	HBrO ₃	HIO ₃	<i>Hallic acid</i>
+7	HClO ₄	HBrO ₄	HIO ₄	<i>Perhalic acid</i>

The hydrogen halides form hydrohalic acid solutions when dissolved in water. These solutions have the characteristic properties of acids, such as reactions with active metals to produce hydrogen gas. ∞ (Section 4.4) Hydrofluoric acid also reacts readily with **silica** (SiO₂) and with silicates to form hexafluorosilicic acid (H₂SiF₆):

Interhalogen Compounds

Because the halogens exist as diatomic molecules, diatomic molecules made up of two different halogen atoms exist. These compounds are the simplest examples of **interhalogens**, compounds, such as ClF and IF₅, formed between two halogen elements.

With one exception, the higher interhalogen compounds have a central Cl, Br, or I atom surrounded by 3, 5, or 7 fluorine atoms. The large size of the iodine atom allows the formation of IF₃, IF₅, and IF₇, in which the oxidation state of I is +3, +5, and +7, respectively. With the smaller bromine and chlorine atoms, only compounds with 3 or 5 fluorines form. The only higher interhalogen compounds that do not have outer F atoms are ICl₃ and ICl₅; the large size of the I atom can accommodate 5 Cl atoms, whereas Br is not large enough to allow even BrCl₃ to form. All of the interhalogen compounds are powerful oxidizing agents.

Oxyacids and Oxyanions

▲ TABLE 22.3 summarizes the formulas of the known oxyacids of the halogens and the way they are named.* ∞ (Section 2.8) The acid strengths of the oxyacids increase with increasing oxidation state of the central halogen atom. ∞ (Section 16.10) All the oxyacids are strong oxidizing agents. The oxyanions, formed on removal of H⁺ from the oxyacids, are generally more stable than the oxyacids. Hypochlorite salts are used as bleaches and disinfectants because of the powerful oxidizing capabilities of the ClO⁻ ion. Sodium hypochlorite is used as a bleaching agent. Chlorate salts are similarly very reactive. For example, potassium chlorate is used to make matches and fireworks.

▲ GIVE IT SOME THOUGHT

Which do you expect to be the stronger oxidizing agent, NaBrO₃ or NaClO₃?

Perchloric acid and its salts are the most stable oxyacids and oxyanions. Dilute solutions of perchloric acid are quite safe, and many perchlorate salts are stable except when heated with organic materials. When heated, however, perchlorates can become vigorous, even violent, oxidizers. Considerable caution should be exercised, therefore, when handling these substances, and it is crucial to avoid contact between perchlorates and readily oxidized material. The use of ammonium perchlorate (NH₄ClO₄) as the oxidizer in the solid booster rockets for the Space Shuttle demonstrates the oxidizing power of perchlorates. The solid propellant contains a mixture of NH₄ClO₄ and powdered aluminum, the reducing agent. Each shuttle launch requires about 6 × 10⁵ kg (700 tons) of NH₄ClO₄ (► FIGURE 22.11).

*Fluorine forms one oxyacid, HOF. Because the electronegativity of fluorine is greater than that of oxygen, we must consider fluorine to be in a -1 oxidation state and oxygen to be in the 0 oxidation state in this compound.

The large volume of gases produced provides thrust for the booster rockets

▲ FIGURE 22.11 Launch of the Space Shuttle *Columbia* from the Kennedy Space Center.

CHEMISTRY AND LIFE

HOW MUCH PERCHLORATE IS TOO MUCH?

Since the 1950s both NASA and the Pentagon have used ammonium perchlorate, NH_4ClO_4 , as a rocket fuel. The result is that traces of perchlorate ion are found in groundwater in many regions of the United States, with levels ranging from about 4 to 100 ppb.

Perchlorate is known to suppress thyroid hormone levels in humans. However, it is disputed whether the amounts found in drinking water are sufficiently high to cause health problems. The Environmental Protection Agency currently states that a dose of

0.007 mg per kilogram of body mass per day is not expected to cause adverse health effects in humans. For a 70-kg (154-lb.) person drinking 2 L of water per day, that amounts to a concentration of 25 ppb. California has proposed a standard of 6 ppb.

Removal of perchlorate ion from water supplies is not easy. Although perchlorate is an oxidizing agent, the ClO_4^- ion is quite stable in aqueous solution. One promising avenue is reduction by microorganisms. While research continues on the best means of decreasing perchlorate levels in drinking water, federal agencies continue to explore what level constitutes a safe upper limit.

RELATED EXERCISE: 22.93

▲ **FIGURE 22.12** *Oxygen* is the name of a play by the chemists Carl Djerassi (Stanford University) and Roald Hoffmann (Cornell University). Its subject is the controversy over who discovered oxygen.

22.5 OXYGEN

By the middle of the seventeenth century, scientists recognized that air contained a component associated with burning and breathing. That component was not isolated until 1774, however, when English scientist Joseph Priestley discovered oxygen. Lavoisier subsequently named the element *oxygen*, meaning “acid former.” There is some historical debate about who “really” discovered oxygen, and the debate is the subject of a play written by the chemist-authors Carl Djerassi and Roald Hoffmann (◀ **FIGURE 22.12**).

Oxygen is found in combination with other elements in a great variety of compounds—water (H_2O), silica (SiO_2), alumina (Al_2O_3), and the iron oxides (Fe_2O_3 , Fe_3O_4) are obvious examples. Indeed, oxygen is the most abundant element by mass both in Earth’s crust and in the human body. ∞ (Section 1.2) It is the oxidizing agent for the metabolism of our foods and is crucial to human life.

Properties of Oxygen

Oxygen has two allotropes, O_2 and O_3 . When we speak of molecular oxygen or simply oxygen, it is usually understood that we are speaking of *dioxygen* (O_2), the normal form of the element; O_3 is ozone.

At room temperature, dioxygen is a colorless, odorless gas. It condenses to a liquid at -183°C and freezes at -218°C . It is only slightly soluble in water (0.04 g/L, or 0.001 M at 25°C), but its presence in water is essential to marine life.

The electron configuration of the oxygen atom is $[\text{He}]2s^22p^4$. Thus, oxygen can complete its octet of valence electrons either by picking up two electrons to form the oxide ion (O^{2-}) or by sharing two electrons. In its covalent compounds, it tends to form either two single bonds, as in H_2O , or a double bond, as in formaldehyde ($\text{H}_2\text{C}=\text{O}$). The O_2 molecule contains a double bond. The bond in O_2 is very strong (bond enthalpy 495 kJ/mol). Oxygen also forms strong bonds with many other elements. Consequently, many oxygen-containing compounds are thermodynamically more stable than O_2 . In the absence of a catalyst, however, most reactions of O_2 have high activation energies and thus require high temperatures to proceed at a suitable rate. Once a sufficiently exothermic reaction begins, it may accelerate rapidly, producing a reaction of explosive violence.

Production of Oxygen

Nearly all commercial oxygen is obtained from air. The normal boiling point of O_2 is -183°C , whereas that of N_2 , the other principal component of air, is -196°C . Thus, when air is liquefied and then allowed to warm, the N_2 boils off, leaving liquid O_2 contaminated mainly by small amounts of N_2 and Ar.

In the laboratory, O_2 can be obtained by heating either aqueous hydrogen peroxide or solid potassium chlorate (KClO_3):

Manganese dioxide (MnO_2) catalyzes both reactions.

Much of the O_2 in the atmosphere is replenished through photosynthesis, in which green plants use the energy of sunlight to generate O_2 (along with glucose, $C_6H_{12}O_6$) from atmospheric CO_2 :

Uses of Oxygen

In industrial use, oxygen ranks behind only sulfuric acid (H_2SO_4) and nitrogen (N_2). About 3×10^{10} kg (30 million tons) of O_2 is used annually in the United States. It is shipped and stored either as a liquid or in steel containers as a compressed gas. About 70% of the O_2 output, however, is generated where it is needed.

Oxygen is by far the most widely used oxidizing agent in industry. Over half of the O_2 produced is used in the steel industry, mainly to remove impurities from steel. It is also used to bleach pulp and paper. (Oxidation of colored compounds often gives colorless products.) Oxygen is used together with acetylene (C_2H_2) in oxyacetylene welding (► **FIGURE 22.13**). The reaction between C_2H_2 and O_2 is highly exothermic, producing temperatures in excess of 3000 °C.

▲ **FIGURE 22.13** Welding with an oxyacetylene torch.

Ozone

Ozone is a pale blue, poisonous gas with a sharp, irritating odor. Most people can detect about 0.01 ppm in air. Exposure to 0.1 to 1 ppm produces headaches, burning eyes, and irritation to the respiratory passages.

The O_3 molecule possesses a π bond that is delocalized over the three oxygen atoms. ∞ (Section 8.6) The molecule dissociates readily, forming reactive oxygen atoms:

▲ GIVE IT SOME THOUGHT

What wavelength of light is needed to break an O—O bond in ozone?

Ozone is a stronger oxidizing agent than dioxygen. Ozone forms oxides with many elements under conditions where O_2 will not react; indeed, it oxidizes all the common metals except gold and platinum.

Ozone can be prepared by passing electricity through dry O_2 in a flow-through apparatus. The electrical discharge causes the O_2 bond to break, resulting in reactions like those described in Section 18.1. During thunderstorms, ozone is generated (and can be smelled, if you are too close) from lightning strikes:

Ozone cannot be stored for long, except at low temperature, because it readily decomposes to O_2 . The decomposition is catalyzed by Ag, Pt, and Pd and by many transition-metal oxides.

SAMPLE EXERCISE 22.6 Calculating an Equilibrium Constant

Using ΔG_f° for ozone from Appendix C, calculate the equilibrium constant for Equation 22.24 at 298.0 K, assuming no electrical input.

SOLUTION

Analyze We are asked to calculate the equilibrium constant for the formation of O_3 from O_2 , given the temperature and ΔG_f° .

Plan The relationship between the standard free-energy change, ΔG_f° , for a reaction and the equilibrium constant for the reaction is given in Equation 19.20.

Solve From Appendix C we have

$$\Delta G_f^\circ(O_3) = 163.4 \text{ kJ/mol}$$

Thus, for Equation 22.24,

$$\Delta G^\circ = (2 \text{ mol } O_3)(163.4 \text{ kJ/mol } O_3) = 326.8 \text{ kJ}$$

From Equation 19.20 we have

$$\Delta G^\circ = -RT \ln K$$

Thus,

$$\ln K = \frac{-\Delta G^\circ}{RT} = \frac{-326.8 \times 10^3 \text{ J}}{(8.314 \text{ J/K}\cdot\text{mol})(298.0 \text{ K})} = -131.9$$

$$K = e^{-131.9} = 5.207 \times 10^{-58}$$

Comment In spite of the unfavorable equilibrium constant, ozone can be prepared from O₂ as described in the preceding text. The unfavorable free energy of formation is overcome by energy from the

electrical discharge, and O₃ is removed before the reverse reaction can occur, so a nonequilibrium mixture results.

PRACTICE EXERCISE

Using the data in Appendix C, calculate ΔG° and K for Equation 22.23 at 298.0 K.

Answer: $\Delta G^\circ = 66.7 \text{ kJ}$, $K = 2.03 \times 10^{-12}$

Ozone is sometimes used to treat drinking water. Like Cl₂, ozone kills bacteria and oxidizes organic compounds. The largest use of ozone, however, is in the preparation of pharmaceuticals, synthetic lubricants, and other commercially useful organic compounds, where O₃ is used to sever carbon–carbon double bonds.

Ozone is an important component of the upper atmosphere, where it screens out ultraviolet radiation and so protects us from the effects of these high-energy rays. For this reason, depletion of stratospheric ozone is a major scientific concern. ∞ (Section 18.2) In the lower atmosphere, ozone is considered an air pollutant and is a major constituent of smog. ∞ (Section 18.2) Because of its oxidizing power, ozone damages living systems and structural materials, especially rubber.

Oxides

The electronegativity of oxygen is second only to that of fluorine. As a result, oxygen has negative oxidation states in all compounds except OF₂ and O₂F₂. The –2 oxidation state is by far the most common. Compounds in this oxidation state are called *oxides*.

Nonmetals form covalent oxides, most of which are simple molecules with low melting and boiling points. SiO₂ and B₂O₃, however, have extended structures. Most nonmetal oxides combine with water to give oxyacids. Sulfur dioxide (SO₂), for example, dissolves in water to give sulfurous acid (H₂SO₃):

This reaction and that of SO₃ with H₂O to form H₂SO₄ are largely responsible for acid rain. ∞ (Section 18.2) The analogous reaction of CO₂ with H₂O to form carbonic acid (H₂CO₃) causes the acidity of carbonated water.

Oxides that form acids when they react with water are called either **acidic anhydrides** (anhydride means “without water”) or **acidic oxides**. A few nonmetal oxides, especially ones with the nonmetal in a low oxidation state—such as N₂O, NO, and CO—do not react with water and are not acidic anhydrides.

GIVE IT SOME THOUGHT

What acid is produced by the reaction of I₂O₅ with water?

Most metal oxides are ionic compounds. The ionic oxides that dissolve in water form hydroxides and, consequently, are called either **basic anhydrides** or **basic oxides**. Barium oxide, for example, reacts with water to form barium hydroxide (► FIGURE 22.14). These kinds of reactions are due to the high basicity of the O^{2–} ion and its virtually complete hydrolysis in water:

Even those ionic oxides that are insoluble in water tend to dissolve in strong acids. Iron(III) oxide, for example, dissolves in acids:

This reaction is used to remove rust (Fe₂O₃ · nH₂O) from iron or steel before a protective coat of zinc or tin is applied.

Oxides that can exhibit both acidic and basic character are said to be *amphoteric*. ∞ (Section 17.5) If a metal forms more than one oxide, the basic character of the oxide decreases as the oxidation state of the metal increases (◀ TABLE 22.4).

TABLE 22.4 • Acid–Base Character of Chromium Oxides

Oxide	Oxidation State of Cr	Nature of Oxide
CrO	+2	Basic
Cr ₂ O ₃	+3	Amphoteric
CrO ₃	+6	Acidic

GO FIGURE

Is this reaction a redox reaction?

▲ FIGURE 22.14 Reaction of a basic oxide with water.

Peroxides and Superoxides

Compounds containing O—O bonds and oxygen in the -1 oxidation state are *peroxides*. Oxygen has an oxidation state of $-\frac{1}{2}$ in O_2^- , which is called the *superoxide* ion. The most active (easily oxidized) metals (K, Rb, and Cs) react with O_2 to give superoxides (KO_2 , RbO_2 , and CsO_2). Their active neighbors in the periodic table (Na, Ca, Sr, and Ba) react with O_2 , producing peroxides (Na_2O_2 , CaO_2 , SrO_2 , and BaO_2). Less active metals and nonmetals produce normal oxides. ∞ (Section 7.6)

When superoxides dissolve in water, O_2 is produced:

Because of this reaction, potassium superoxide is used as an oxygen source in masks worn by rescue workers (► FIGURE 22.15). For proper breathing in toxic environments, oxygen must be generated in the mask and exhaled carbon dioxide in the mask must be eliminated. Moisture in the breath causes the KO_2 to decompose to O_2 and KOH , and the KOH removes CO_2 from the exhaled breath:

Hydrogen peroxide (► FIGURE 22.16) is the most familiar and commercially important peroxide. Pure hydrogen peroxide is a clear, syrupy liquid that melts at -0.4°C . Concentrated hydrogen peroxide is dangerously reactive because the decomposition to water and oxygen is very exothermic:

This is another example of a **disproportionation** reaction, in which an element is simultaneously oxidized and reduced. The oxidation number of oxygen changes from -1 to -2 and 0 .

Hydrogen peroxide is marketed as a chemical reagent in aqueous solutions of up to about 30% by mass. A solution containing about 3% H_2O_2 by mass is sold in drugstores and used as a mild antiseptic. Somewhat more concentrated solutions are used to bleach fabrics.

The peroxide ion is a by-product of metabolism that results from the reduction of O_2 . The body disposes of this reactive ion with enzymes such as peroxidase and catalase.

22.6 THE OTHER GROUP 6A ELEMENTS: S, Se, Te, AND Po

6A	8	O
	16	S
	34	Se
	52	Te
	84	Po

The other group 6A elements are sulfur, selenium, tellurium, and polonium. In this section we will survey the properties of the group as a whole and then examine the chemistry of sulfur, selenium, and tellurium. We will not say much about polonium, which has no stable isotopes and is found only in minute quantities in radium-containing minerals.

General Characteristics of the Group 6A Elements

The group 6A elements possess the general outer-electron configuration ns^2np^4 with n ranging from 2 to 6. Thus, these elements attain a noble-gas electron configuration by adding two electrons, which results in a -2 oxidation state. Except for oxygen, the group 6A elements are also commonly found in positive oxidation states up to $+6$, and they can have expanded valence shells. Thus, we have such compounds as SF_6 , SeF_6 , and TeF_6 with the central atom in the $+6$ oxidation state.

▼ **TABLE 22.5** summarizes some properties of the group 6A elements.

Occurrence and Production of S, Se, and Te

Sulfur, selenium, and tellurium can all be mined from the earth. Large underground deposits are the principal source of elemental sulfur (◀ **FIGURE 22.17**). Sulfur also occurs widely as sulfide (S^{2-}) and sulfate (SO_4^{2-}) minerals. Its presence as a minor component of coal and petroleum poses a major problem. Combustion of these “unclean” fuels leads to serious pollution by sulfur oxides. ∞ (Section 18.2) Much effort has been directed at removing this sulfur, and these efforts have increased the availability of sulfur. The sale of this sulfur helps to partially offset the costs of the desulfurizing processes and equipment.

Selenium and tellurium occur in rare minerals, such as Cu_2Se , $PbSe$, Cu_2Te , and $PbTe$, and as minor constituents in sulfide ores of copper, iron, nickel, and lead.

▲ **FIGURE 22.17** Massive amounts of sulfur are extracted every year from the earth.

Properties and Uses of Sulfur, Selenium, and Tellurium

Elemental sulfur is yellow, tasteless, and nearly odorless. It is insoluble in water and exists in several allotropic forms. The thermodynamically stable form at room temperature is rhombic sulfur, which consists of puckered S_8 rings. ∞ (Figure 7.26) When heated above its melting point ($113^\circ C$), molten sulfur first contains S_8 molecules and is fluid because the rings slip over one another. Further heating causes the rings to break; the fragments then join to form long molecules that can become entangled. In this polymeric form, sulfur becomes highly viscous. Further heating breaks the chains, and the viscosity again decreases.

Most of the approximately 1×10^{10} kg (10 million tons) of sulfur produced in the United States each year is used to manufacture sulfuric acid. Sulfur is also used to vulcanize rubber, a process that toughens rubber by introducing cross-linking between polymer chains. ∞ (Section 12.8)

TABLE 22.5 • Some Properties of the Group 6A Elements

Property	O	S	Se	Te
Atomic radius (Å)	0.73	1.04	1.17	1.43

*Based on O—O bond energy in H_2O_2 .

Selenium and tellurium do not form eight-membered rings in their elemental forms. ∞ (Section 7.8) The most stable allotropes of these elements are crystalline substances containing helical chains of atoms (► FIGURE 22.18). Each atom is close to atoms in adjacent chains, and it appears that some sharing of electron pairs between these atoms occurs.

The electrical conductivity of elemental selenium is low in the dark but increases greatly upon exposure to light. This property is exploited in photoelectric cells and light meters. Photocopiers also depend on the photoconductivity of selenium. Photocopy machines contain a belt or drum coated with a film of selenium. This drum is electrostatically charged and then exposed to light reflected from the image being photocopied. The charge drains from the regions where the selenium film has been made conductive by exposure to light. A black powder (the toner) sticks only to the areas that remain charged. The photocopy is made when the toner is transferred to a sheet of plain paper.

▲ FIGURE 22.18 Portion of helical chains making up the structure of crystalline selenium.

Sulfides

When an element is less electronegative than sulfur, *sulfides* that contain S^{2-} form. Many metallic elements are found in the form of sulfide ores, such as PbS (galena) and HgS (cinnabar). A series of related ores containing the disulfide ion, S_2^{2-} (analogous to the peroxide ion), are known as *pyrites*. Iron pyrite, FeS_2 , occurs as golden yellow cubic crystals (► FIGURE 22.19). Because it has been occasionally mistaken for gold by miners, iron pyrite is often called fool's gold.

One of the most important sulfides is hydrogen sulfide (H_2S). This substance is not normally produced by direct union of the elements because it decomposes at elevated temperatures. It is normally prepared by action of dilute acid on iron(II) sulfide:

One of hydrogen sulfide's most readily recognized properties is its odor, which is most frequently encountered as the offensive odor of rotten eggs. Hydrogen sulfide is toxic but our noses can detect H_2S in extremely low, nontoxic concentrations. A sulfur-containing organic molecule, such as dimethyl sulfide, $(CH_3)_2S$, which is similarly odoriferous and can be detected by smell at a level of one part per trillion, is added to natural gas as a safety factor to give it a detectable odor.

▲ FIGURE 22.19 Iron pyrite (FeS_2 , on the right) with gold for comparison.

Oxides, Oxyacids, and Oxyanions of Sulfur

Sulfur dioxide, formed when sulfur burns in air, has a choking odor and is poisonous. The gas is particularly toxic to lower organisms, such as fungi, so it is used to sterilize dried fruit and wine. At 1 atm and room temperature, SO_2 dissolves in water to produce a 1.6 M solution. The SO_2 solution is acidic, and we describe it as sulfurous acid (H_2SO_3).

Salts of SO_3^{2-} (sulfites) and HSO_3^- (hydrogen sulfites or bisulfites) are well known. Small quantities of Na_2SO_3 or $NaHSO_3$ are used as food additives to prevent bacterial spoilage. Because some people are extremely allergic to sulfites, all food products with sulfites must now carry a warning label disclosing their presence.

Although combustion of sulfur in air produces mainly SO_2 , small amounts of SO_3 are also formed. The reaction produces chiefly SO_2 because the activation-energy barrier for oxidation to SO_3 is very high unless the reaction is catalyzed. Interestingly, the SO_3 by-product is used industrially to make H_2SO_4 , which is the ultimate product of the reaction between SO_3 and water. In the manufacture of sulfuric acid, SO_2 is obtained by burning sulfur and then oxidized to SO_3 , using a catalyst such as V_2O_5 or platinum. The SO_3 is dissolved in H_2SO_4 because it does not dissolve quickly in water, and then the $H_2S_2O_7$ formed in this reaction, called pyrosulfuric acid, is added to water to form H_2SO_4 :

GO FIGURE

In this reaction, what has happened to the H and O atoms in the sucrose?

► **FIGURE 22.20** Sulfuric acid dehydrates table sugar to produce elemental carbon.

GIVE IT SOME THOUGHT

What is the net reaction of Equations 22.32 and 22.33?

Commercial sulfuric acid is 98% H_2SO_4 . It is a dense, colorless, oily liquid that boils at 340°C . It is a strong acid, a good dehydrating agent (▲ **FIGURE 22.20**), and a moderately good oxidizing agent.

Year after year, the production of sulfuric acid is the largest of any chemical produced in the United States. About 4×10^{10} kg (40 million tons) is produced annually in this country. Sulfuric acid is employed in some way in almost all manufacturing. Consequently, its consumption is considered a measure of industrial activity.

Sulfuric acid is a strong acid, but only the first hydrogen is completely ionized in aqueous solution:

Consequently, sulfuric acid forms both sulfates (SO_4^{2-} salts) and bisulfates (or hydrogen sulfates, HSO_4^- salts). Bisulfate salts are common components of the “dry acids” used for adjusting the pH of swimming pools and hot tubs; they are also components of many toilet bowl cleaners.

The term *thio* indicates substitution of sulfur for oxygen, and the thiosulfate ion ($\text{S}_2\text{O}_3^{2-}$) is formed by boiling an alkaline solution of SO_3^{2-} with elemental sulfur:

The structures of the sulfate and thiosulfate ions are compared in ◀ **FIGURE 22.21**. Thiosulfate salts are used industrially in the paper-making and textile industries and are the “fixer” solutions in the development of photographic film.

GO FIGURE

22.7 | NITROGEN

In 1772 the Scottish botanist Daniel Rutherford found that a mouse enclosed in a sealed jar quickly consumed the life-sustaining component of air (oxygen) and died. When the “fixed air” (CO₂) in the container was removed, a “noxious air” remained that would not sustain combustion or life. We now know that gas as *nitrogen*.

Nitrogen constitutes 78% by volume of Earth’s atmosphere, where it occurs as N₂ molecules. Although nitrogen is a key element in living organisms, compounds of nitrogen are not abundant in Earth’s crust. The major natural deposits of nitrogen compounds are those of KNO₃ (saltpeter) in India and NaNO₃ (Chile saltpeter) in Chile and other desert regions of South America.

Properties of Nitrogen

Nitrogen is a colorless, odorless, tasteless gas composed of N₂ molecules. Its melting point is –210 °C, and its normal boiling point is –196 °C.

The N₂ molecule is very unreactive because of the strong triple bond between nitrogen atoms (the N≡N bond enthalpy is 941 kJ/mol, nearly twice that for the bond in O₂; ∞ Table 8.4). When substances burn in air, they normally react with O₂ but not with N₂. When magnesium burns in air, however, it reacts with N₂ to form magnesium nitride (Mg₃N₂):

A similar reaction occurs with lithium, forming Li₃N.

The nitride ion is a strong Brønsted–Lowry base and reacts with water to form ammonia:

The electron configuration of the nitrogen atom is [He]2s²2p³. The element exhibits all formal oxidation states from +5 to –3 (► TABLE 22.6). The +5, 0, and –3 oxidation states are the most common and generally the most stable of these. Because nitrogen is more electronegative than all other elements except fluorine, oxygen, and chlorine, it exhibits positive oxidation states only in combination with these three elements.

TABLE 22.6 • Oxidation States of Nitrogen

Oxidation State	Examples
+5	N ₂ O ₅ , HNO ₃ , NO ₃ [–]
+4	NO ₂ , N ₂ O ₄
+3	HNO ₂ , NO ₂ [–] , NF ₃
+2	NO
+1	N ₂ O, H ₂ N ₂ O ₂ , N ₂ O ₂ ^{2–} , HNF ₂
0	N ₂
–1	NH ₂ OH, NH ₂ F
–2	N ₂ H ₄
–3	NH ₃ , NH ₄ ⁺ , NH ₂ [–]

Production and Uses of Nitrogen

Elemental nitrogen is obtained in commercial quantities by fractional distillation of liquid air. About 4 × 10¹⁰ kg (40 million tons) of N₂ is produced annually in the United States.

Because of its low reactivity, large quantities of N₂ are used as an inert gaseous blanket to exclude O₂ in food processing, manufacture of chemicals, metal fabrication, and production of electronic devices. Liquid N₂ is employed as a coolant to freeze foods rapidly.

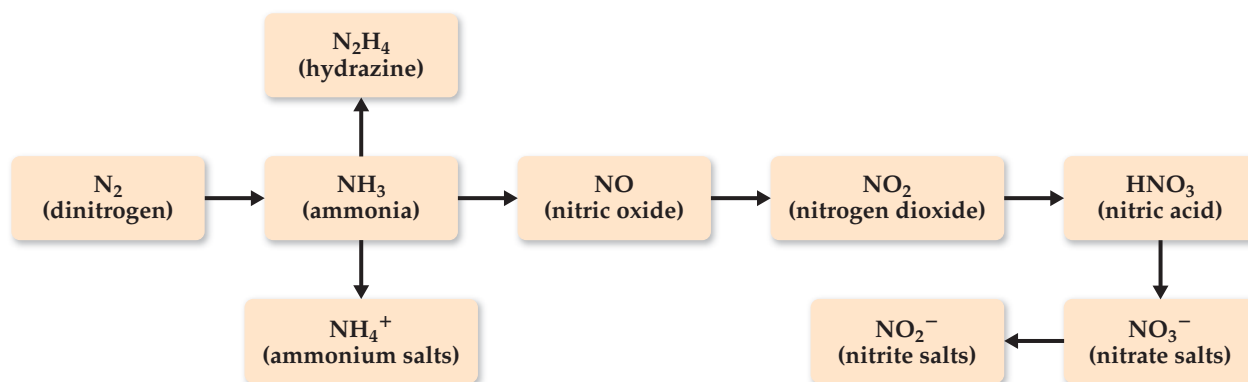

The largest use of N₂ is in the manufacture of nitrogen-containing fertilizers, which provide a source of *fixed* nitrogen. We have previously discussed nitrogen fixation in the “Chemistry and Life” box in Section 14.7 and in the “Chemistry Put to Work” box in Section 15.2. Our starting point in fixing nitrogen is the manufacture of ammonia via the Haber process. ∞ (Section 15.2) The ammonia can then be converted into a variety of useful, simple nitrogen-containing species (► FIGURE 22.22).

Hydrogen Compounds of Nitrogen

Ammonia is one of the most important compounds of nitrogen. It is a colorless, toxic gas that has a characteristic irritating odor. As noted in previous discussions, the NH₃ molecule is basic (*K_b* = 1.8 × 10^{–5}). ∞ (Section 16.7)

GO FIGURE

In which of these species is the oxidation number of nitrogen +3?

▲ FIGURE 22.22 Sequence of conversion of N_2 into common nitrogen compounds.

GO FIGURE

Is the N—N bond length in these molecules shorter or longer than the N—N bond length in N_2 ?

▲ FIGURE 22.23 Hydrazine (top, N_2H_4) and methylhydrazine (bottom, CH_3NHNH_2).

In the laboratory, NH_3 can be prepared by the action of $NaOH$ on an ammonium salt. The NH_4^+ ion, which is the conjugate acid of NH_3 , transfers a proton to OH^- . The resultant NH_3 is volatile and is driven from the solution by mild heating:

Commercial production of NH_3 is achieved by the Haber process:

About 1×10^{10} kg (10 million tons) of ammonia is produced annually in the United States. About 75% is used for fertilizer.

Hydrazine (N_2H_4) is another important hydride of nitrogen. The hydrazine molecule contains an N—N single bond (◀ FIGURE 22.23). Hydrazine is quite poisonous. It can be prepared by the reaction of ammonia with hypochlorite ion (OCl^-) in aqueous solution:

The reaction involves several intermediates, including chloramine (NH_2Cl). The poisonous NH_2Cl bubbles out of solution when household ammonia and chlorine bleach (which contains OCl^-) are mixed. This reaction is one reason for the frequently cited warning not to mix bleach and household ammonia.

Pure hydrazine is a strong and versatile reducing agent. The major use of hydrazine and compounds related to it, such as methylhydrazine (Figure 22.23), is as rocket fuel.

SAMPLE EXERCISE 22.7 Writing a Balanced Equation

Hydroxylamine (NH_2OH) reduces copper(II) to the free metal in acid solutions. Write a balanced equation for the reaction, assuming that N_2 is the oxidation product.

SOLUTION

Analyze We are asked to write a balanced oxidation-reduction equation in which NH_2OH is converted to N_2 and Cu^{2+} is converted to Cu .

Plan Because this is a redox reaction, the equation can be balanced by the method of half-reactions discussed in Section 20.2. Thus, we begin with two half-reactions, one involving the NH_2OH and N_2 and the other involving Cu^{2+} and Cu .

Solve The unbalanced and incomplete half-reactions are

$$Cu^{2+}(aq) \longrightarrow Cu(s)$$

$$NH_2OH(aq) \longrightarrow N_2(g)$$

Balancing these equations as described in Section 20.2 gives

Adding these half-reactions gives the balanced equation:

PRACTICE EXERCISE

(a) In power plants, hydrazine is used to prevent corrosion of the metal parts of steam boilers by the O_2 dissolved in the water. The hydrazine reacts with O_2 in water to give N_2 and H_2O . Write a balanced equation for this reaction. (b) Methylhydrazine, $\text{N}_2\text{H}_3\text{CH}_3(\text{l})$, is used

with the oxidizer dinitrogen tetroxide, $\text{N}_2\text{O}_4(\text{l})$, to power the steering rockets of the Space Shuttle orbiter. The reaction of these two substances produces N_2 , CO_2 , and H_2O . Write a balanced equation for this reaction.

Answers: (a) $\text{N}_2\text{H}_4(\text{aq}) + \text{O}_2(\text{aq}) \longrightarrow \text{N}_2(\text{g}) + 2 \text{H}_2\text{O}(\text{l})$;

(b) $5 \text{N}_2\text{O}_4(\text{l}) + 4 \text{N}_2\text{H}_3\text{CH}_3(\text{l}) \longrightarrow 9 \text{N}_2(\text{g}) + 4 \text{CO}_2(\text{g}) + 12 \text{H}_2\text{O}(\text{g})$

Oxides and Oxyacids of Nitrogen

Nitrogen forms three common oxides: N_2O (nitrous oxide), NO (nitric oxide), and NO_2 (nitrogen dioxide). It also forms two unstable oxides that we will not discuss, N_2O_3 (dinitrogen trioxide) and N_2O_5 (dinitrogen pentoxide).

Nitrous oxide (N_2O) is also known as laughing gas because a person becomes giddy after inhaling a small amount. This colorless gas was the first substance used as a general anesthetic. It is used as the compressed gas propellant in several aerosols and foams, such as in whipped cream. It can be prepared in the laboratory by carefully heating ammonium nitrate to about 200°C :

Nitric oxide (NO) is also a colorless gas but, unlike N_2O , it is slightly toxic. It can be prepared in the laboratory by reduction of dilute nitric acid, using copper or iron as a reducing agent (▼ **FIGURE 22.24**):

Nitric oxide is also produced by direct reaction of N_2 and O_2 at high temperatures. This reaction is a significant source of nitrogen oxide air pollutants. ∞ (Section 18.2) The direct combination of N_2 and O_2 is not used for commercial production of NO , however, because the yield is low, the equilibrium constant K_p at 2400 K being only 0.05. ∞ (Section 15.7, “Chemistry Put to Work: Controlling Nitric Oxide Emissions”)

The commercial route to NO (and hence to other oxygen-containing compounds of nitrogen) is via the catalytic oxidation of NH_3 :

This reaction is the first step in the **Ostwald process**, by which NH_3 is converted commercially into nitric acid (HNO_3).

◀ **FIGURE 22.24** Copper metal reacts with nitric acid to produce blue $\text{Cu}^{2+}(\text{aq})$ and $\text{NO}(\text{g})$.

▲ FIGURE 22.25 Formation of $\text{NO}_2(\text{g})$ as $\text{NO}(\text{g})$ combines with $\text{O}_2(\text{g})$ in the air.

When exposed to air, nitric oxide reacts readily with O_2 (▲ FIGURE 22.25):

When dissolved in water, NO_2 forms nitric acid:

Nitrogen is both oxidized and reduced in this reaction, which means it disproportionates. The NO can be converted back into NO_2 by exposure to air (Equation 22.45) and thereafter dissolved in water to prepare more HNO_3 .

NO is an important neurotransmitter in the human body. It causes the muscles that line blood vessels to relax, thus allowing an increased passage of blood (see the “Chemistry and Life” box on page 941).

Nitrogen dioxide (NO_2) is a yellow-brown gas (Figure 22.25). Like NO , it is a major constituent of smog. ∞ (Section 18.2) It is poisonous and has a choking odor. As discussed in Section 15.1, NO_2 and N_2O_4 exist in equilibrium:

The two common oxyacids of nitrogen are nitric acid (HNO_3) and nitrous acid (HNO_2) (◀ FIGURE 22.26). *Nitric acid* is a strong acid. It is also a powerful oxidizing agent, as indicated by the standard reduction potential in the reaction

Concentrated nitric acid attacks and oxidizes most metals except Au , Pt , Rh , and Ir .

About 7×10^9 kg (8 million tons) of nitric acid is produced annually in the United States. Its largest use is in the manufacture of NH_4NO_3 for fertilizers. It is also used in the production of plastics, drugs, and explosives. Among the explosives made from nitric acid are nitroglycerin, trinitrotoluene (TNT), and nitrocellulose. The following reaction occurs when nitroglycerin explodes:

All the products of this reaction contain very strong bonds and are gases. As a result, the reaction is very exothermic, and the volume of the products is far larger than the volume occupied by the reactant. Thus, the expansion resulting from the heat generated by the reaction produces the explosion. ∞ (Section 8.8: “Chemistry Put to Work: Explosives and Alfred Nobel”)

Nitrous acid is considerably less stable than HNO_3 and tends to disproportionate into NO and HNO_3 . It is normally made by action of a strong acid, such as H_2SO_4 , on a cold solution of a nitrite salt, such as NaNO_2 . Nitrous acid is a weak acid ($K_a = 4.5 \times 10^{-4}$).

- nitric acid;
- nitrous acid?

CHEMISTRY AND LIFE

NITROGLYCERIN AND HEART DISEASE

During the 1870s an interesting observation was made in Alfred Nobel's dynamite factories. Workers who suffered from heart disease that caused chest pains when they exerted themselves found relief from the pains during the workweek. It quickly became apparent that nitroglycerin, present in the air of the factory, acted to enlarge blood vessels. Thus, this powerfully explosive chemical became a standard treatment for angina pectoris, the chest pains accompanying heart failure. It took more than 100 years to discover that nitroglycerin was converted in the vascular smooth muscle into NO, which is the chemical agent actually causing dilation of the

blood vessels. In 1998 the Nobel Prize in Physiology or Medicine was awarded to Robert F. Furchgott, Louis J. Ignarro, and Ferid Murad for their discoveries of the detailed pathways by which NO acts in the cardiovascular system. It was a sensation that this simple, common air pollutant could exert important functions in mammals, including humans.

As useful as nitroglycerin is to this day in treating angina pectoris, it has a limitation in that prolonged administration results in development of tolerance, or desensitization, of the vascular muscle to further vasorelaxation by nitroglycerin. The bioactivation of nitroglycerin is the subject of active research in the hope that a means of circumventing desensitization can be found.

22.8 THE OTHER GROUP 5A ELEMENTS: P, As, Sb, AND Bi

Of the other group 5A elements—phosphorus, arsenic, antimony, and bismuth—phosphorus has a central role in several aspects of biochemistry and environmental chemistry.

General Characteristics of the Group 5A Elements

The group 5A elements have the outer-shell electron configuration ns^2np^3 , with n ranging from 2 to 6. A noble-gas configuration is achieved by adding three electrons to form the -3 oxidation state. Ionic compounds containing X^{3-} ions are not common, however. More commonly, the group 5A element acquires an octet of electrons via covalent bonding and oxidation numbers ranging from -3 to $+5$.

Because of its lower electronegativity, phosphorus is found more frequently in positive oxidation states than is nitrogen. Furthermore, compounds in which phosphorus has the $+5$ oxidation state are not as strongly oxidizing as the corresponding compounds of nitrogen. Compounds in which phosphorus has a -3 oxidation state are much stronger reducing agents than are the corresponding nitrogen compounds.

Some properties of the group 5A elements are listed in ▼ TABLE 22.7. The general pattern is similar to what we saw with other groups: Size and metallic character increase as atomic number increases in the group.

The variation in properties among group 5A elements is more striking than that seen in groups 6A and 7A. Nitrogen at the one extreme exists as a gaseous diatomic molecule, clearly nonmetallic. At the other extreme, bismuth is a reddish white, metallic-looking substance that has most of the characteristics of a metal.

The values listed for X—X single-bond enthalpies are not reliable because it is difficult to obtain such data from thermochemical experiments. However, there is no doubt

Atomic Number	Element
7	N

▲ FIGURE 22.27 White and red phosphorus. Despite the fact that both contain nothing but phosphorus atoms, these two forms of phosphorus differ greatly in reactivity. The white allotrope, which reacts violently with oxygen, must be stored under water so that it is not exposed to air. The much less reactive red form does not need to be stored this way.

about the general trend: a low value for the N—N single bond, an increase at phosphorus, and then a gradual decline to arsenic and antimony. From observations of the elements in the gas phase, it is possible to estimate the X≡X triple-bond enthalpies. Here we see a trend that is different from that for the X—X single bond. Nitrogen forms a much stronger triple bond than the other elements, and there is a steady decline in the triple-bond enthalpy down through the group. These data help us to appreciate why nitrogen alone of the group 5A elements exists as a diatomic molecule in its stable state at 25 °C. All the other elements exist in structural forms with single bonds between the atoms.

Occurrence, Isolation, and Properties of Phosphorus

Phosphorus occurs mainly in the form of phosphate minerals. The principal source of phosphorus is phosphate rock, which contains phosphate principally as $\text{Ca}_3(\text{PO}_4)_2$. The element is produced commercially by reduction of calcium phosphate with carbon in the presence of SiO_2 :

The phosphorus produced in this fashion is the allotrope known as white phosphorus. This form distills from the reaction mixture as the reaction proceeds.

Phosphorus exists in several allotropic forms. White phosphorus consists of P_4 tetrahedra (◀ FIGURE 22.27). The bond angles in this molecule, 60° , are unusually small, so there is much strain in the bonding, which is consistent with the high reactivity of white phosphorus. This allotrope bursts spontaneously into flames if exposed to air. When heated in the absence of air to about 400°C , white phosphorus is converted to a more stable allotrope known as red phosphorus, which does not ignite on contact with air. Red phosphorus is also considerably less poisonous than the white form. We will denote elemental phosphorus as simply P(s).

Phosphorus Halides

Phosphorus forms a wide range of compounds with the halogens, the most important of which are the trihalides and pentahalides. Phosphorus trichloride (PCl_3) is commercially the most significant of these compounds and is used to prepare a wide variety of products, including soaps, detergents, plastics, and insecticides.

Phosphorus chlorides, bromides, and iodides can be made by direct oxidation of elemental phosphorus with the elemental halogen. PCl_3 , for example, which is a liquid at room temperature, is made by passing a stream of dry chlorine gas over white or red phosphorus:

If excess chlorine gas is present, an equilibrium is established between PCl_3 and PCl_5 .

The phosphorus halides hydrolyze on contact with water. The reactions occur readily, and most of the phosphorus halides fume in air because of reaction with water vapor. In the presence of excess water the products are the corresponding phosphorus oxyacid and hydrogen halide:

Oxy Compounds of Phosphorus

Probably the most significant phosphorus compounds are those in which the element is combined with oxygen. Phosphorus(III) oxide (P_4O_6) is obtained by allowing white phosphorus to oxidize in a limited supply of oxygen. When oxidation takes place in the

presence of excess oxygen, phosphorus(V) oxide (P_4O_{10}) forms. This compound is also readily formed by oxidation of P_4O_6 . These two oxides represent the two most common oxidation states for phosphorus, +3 and +5. The structural relationship between P_4O_6 and P_4O_{10} is shown in ► **FIGURE 22.28**. Notice the resemblance these molecules have to the P_4 molecule (Figure 22.27); all three substances have a P_4 core.

SAMPLE EXERCISE 22.8 Calculating a Standard Enthalpy Change

The reactive chemicals on the tip of a “strike anywhere” match are usually P_4S_3 and an oxidizing agent such as KClO_3 . When the match is struck on a rough surface, the heat generated by the friction ignites the P_4S_3 , and the oxidizing agent brings about rapid combustion. The products of the combustion of P_4S_3 are P_4O_{10} and SO_2 . Calculate the standard enthalpy change for the combustion of P_4S_3 in air, given the following standard enthalpies of formation: P_4S_3 (-154.4 kJ/mol), P_4O_{10} (-2940.1 kJ/mol), SO_2 (-296.9 kJ/mol).

SOLUTION

Analyze We are given the reactants (P_4S_3 and O_2 from air) and the products (P_4O_{10} and SO_2) for a reaction, together with their standard enthalpies of formation, and asked to calculate the standard enthalpy change for the reaction.

Plan We first need a balanced chemical equation for the reaction. The enthalpy change for the reaction is then equal to the enthalpies of formation of products minus those of reactants (Equation 5.31). We also need to recall that the standard enthalpy of formation of any element in its standard state is zero. Thus, $\Delta H_f^\circ(\text{O}_2) = 0$.

Solve The balanced chemical equation for the combustion is

Thus, we can write

$$\begin{aligned} \Delta H^\circ &= \Delta H_f^\circ(\text{P}_4\text{O}_{10}) + 3 \Delta H_f^\circ(\text{SO}_2) - \Delta H_f^\circ(\text{P}_4\text{S}_3) - 8 \Delta H_f^\circ(\text{O}_2) \\ &= -2940.1 \text{ kJ} + 3(-296.9) \text{ kJ} - (-154.4 \text{ kJ}) - 8(0) \\ &= -3676.4 \text{ kJ} \end{aligned}$$

Comment The reaction is strongly exothermic, making it evident why P_4S_3 is used on match tips.

PRACTICE EXERCISE

Write the balanced equation for the reaction of P_4O_{10} with water, and calculate ΔH° for this reaction using data from Appendix C.

Answer: $\text{P}_4\text{O}_{10}(\text{s}) + 6 \text{H}_2\text{O}(\text{l}) \longrightarrow 4 \text{H}_3\text{PO}_4(\text{aq}); -498.1 \text{ kJ}$

Phosphorus(V) oxide is the anhydride of phosphoric acid (H_3PO_4), a weak triprotic acid. In fact, P_4O_{10} has a very high affinity for water and is consequently used as a drying agent. Phosphorus(III) oxide is the anhydride of phosphorous acid (H_3PO_3), a weak diprotic acid (► **FIGURE 22.29**)*.

One characteristic of phosphoric and phosphorous acids is their tendency to undergo condensation reactions when heated. ∞ (Section 12.8) For example, two H_3PO_4 molecules are joined by the elimination of one H_2O molecule to form $\text{H}_4\text{P}_2\text{O}_7$:

[22.55]

Phosphoric acid and its salts find their most important uses in detergents and fertilizers. The phosphates in detergents are often in the form of sodium tripolyphosphate ($\text{Na}_5\text{P}_3\text{O}_{10}$).

*Note that the element phosphorus (*FOS*·*for*·*us*) has a *-us* suffix, whereas the first word in the name phosphorous (*fOS*·*FOR*·*us*) acid has an *-ous* suffix.

GO FIGURE
How do the electron domains about P in P_4O_6 differ from those about P in P_4O_{10} ?

▲ **FIGURE 22.28** Structures of P_4O_6 (top) and P_4O_{10} (bottom).

▲ **FIGURE 22.29** Structures of H_3PO_4 (top) and H_3PO_3 (bottom).

The phosphate ions “soften” water by binding their oxygen groups to the metal ions that contribute to the hardness of water. This keeps the metal ions from interfering with the action of the detergent. The phosphates also keep the pH above 7 and thus prevent the detergent molecules from becoming protonated.

Most mined phosphate rock is converted to fertilizers. The $\text{Ca}_3(\text{PO}_4)_2$ in phosphate rock is insoluble ($K_{sp} = 2.0 \times 10^{-29}$). It is converted to a soluble form for use in fertilizers by treatment with sulfuric or phosphoric acid. The reaction with phosphoric acid yields $\text{Ca}(\text{H}_2\text{PO}_4)_2$:

Although the solubility of $\text{Ca}(\text{H}_2\text{PO}_4)_2$ allows it to be assimilated by plants, it also allows it to be washed from the soil and into bodies of water, thereby contributing to water pollution. ∞ (Section 18.4)

Phosphorus compounds are important in biological systems. The element occurs in phosphate groups in RNA and DNA, the molecules responsible for the control of protein biosynthesis and transmission of genetic information. It also occurs in adenosine triphosphate (ATP), which stores energy in biological cells and has the structure

The $\text{P}-\text{O}-\text{P}$ bond of the end phosphate group is broken by hydrolysis with water, forming adenosine diphosphate (ADP):

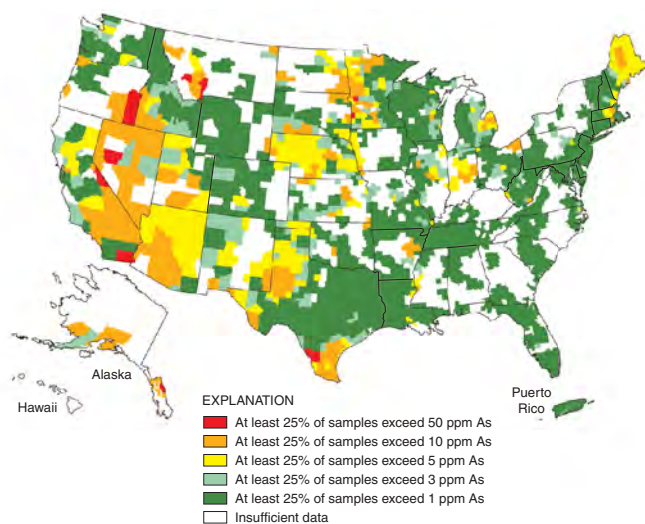

This reaction releases 33 kJ of energy under standard conditions, but in the living cell, the Gibbs free energy change for the reaction is closer to -57 kJ/mol. The concentration of ATP inside a living cell is in the range of 1–10 mM, which means a typical human metabolizes her or his body mass of ATP in one day! ATP is continually made from ADP and continually converted back to ADP, releasing energy that can be harnessed by other cellular reactions.

CHEMISTRY AND LIFE

ARSENIC IN DRINKING WATER

“Arsenic,” meaning its oxides, has been known as a poison for centuries. The current Environmental Protection Agency (EPA) standard for arsenic in public water supplies is 10 ppb (equivalent to $10 \mu\text{g}/\text{L}$). Most regions of the United States tend to have low to moderate (2–10 ppb) groundwater arsenic levels (▼ FIGURE 22.30). The western region tends to have higher levels, coming mainly from natural geological sources in the area. Estimates, for example, indicate that 35% of water-supply wells in Arizona have arsenic concentrations above 10 ppb.

The problem of arsenic in drinking water in the United States is dwarfed by the problem in other parts of the world—especially in Bangladesh, where the problem is tragic. Historically, surface water

▲ FIGURE 22.30 Geographic distribution of arsenic in groundwater.

sources in that country have been contaminated with microorganisms, causing significant health problems, including one of the highest infant mortality rates in the world. During the 1970s, international agencies, headed by the United Nations Children’s Fund (UNICEF), began investing millions of dollars of aid money in Bangladesh for wells to provide “clean” drinking water. Unfortunately, no one tested the well water for the presence of arsenic; the problem was not discovered until the 1980s. The result has been the biggest outbreak of mass poisoning in history. Up to half of the country’s estimated 10 million wells have arsenic concentrations above 50 ppb.

In water the most common forms of arsenic are the arsenate ion and its protonated hydrogen anions (AsO_4^{3-} , HAsO_4^{2-} , and H_2AsO_4^-) and the arsenite ion and its protonated forms (AsO_3^{3-} , HAsO_3^{2-} , H_2AsO_3^- , and H_3AsO_3). These species are collectively referred to by the oxidation number of the arsenic as arsenic(V) and arsenic(III), respectively. Arsenic(V) is more prevalent in oxygen-rich (aerobic) surface waters, whereas arsenic(III) is more likely to occur in oxygen-poor (anaerobic) groundwaters. In the pH range from 4 to 10, the arsenic(V) is present primarily as HAsO_4^{2-} and H_2AsO_4^- , and the arsenic(III) is present primarily as the neutral acid H_3AsO_3 .

One of the challenges in determining the health effects of arsenic in drinking waters is the different chemistry of arsenic(V) and arsenic(III), as well as the different concentrations required for physiological responses in different individuals. In Bangladesh, skin lesions were the first sign of the arsenic problem. Statistical studies correlating arsenic levels with the occurrence of disease indicate a lung and bladder cancer risk arising from even low levels of arsenic.

The current technologies for removing arsenic perform most effectively when treating arsenic in the form of arsenic(V), so water treatment strategies require preoxidation of the drinking water. Once in the form of arsenic(V), there are a number of possible removal strategies. For example, $\text{Fe}_2(\text{SO}_4)_3$ could be added to precipitate FeAsO_4 , which is then removed by filtration.

RELATED EXERCISE: 22.104.

22.9 CARBON

Carbon constitutes only 0.027% of Earth’s crust. Although some carbon occurs in elemental form as graphite and diamond, most is found in combined form. Over half occurs in carbonate compounds, and carbon is also found in coal, petroleum, and natural gas. The importance of the element stems in large part from its occurrence in all living organisms: Life as we know it is based on carbon compounds.

Elemental Forms of Carbon

We have seen that carbon exists in several allotropic crystalline forms: graphite, diamond, fullerenes, carbon nanotubes, and graphene. Fullerenes, nanotubes, and graphene are discussed in Chapter 12; here we focus on graphite and diamond.

Graphite is a soft, black, slippery solid that has a metallic luster and conducts electricity. It consists of parallel sheets of sp^2 -hybridized carbon atoms held together by

dispersion forces. ∞ (Section 12.7) *Diamond* is a clear, hard solid in which the carbon atoms form an sp^3 -hybridized covalent network. ∞ (Section 12.7) Diamond is denser than graphite ($d = 2.25 \text{ g/cm}^3$ for graphite; $d = 3.51 \text{ g/cm}^3$ for diamond). At approximately 100,000 atm at 3000 °C, graphite converts to diamond. In fact, almost any carbon-containing substance, if put under sufficiently high pressure, forms diamonds; scientists at General Electric in the 1950s used peanut butter to make diamonds. About $3 \times 10^4 \text{ kg}$ of industrial-grade diamonds are synthesized each year, mainly for use in cutting, grinding, and polishing tools.

Graphite has a well-defined crystalline structure, but it also exists in two common amorphous forms: **carbon black** and **charcoal**. Carbon black is formed when hydrocarbons are heated in a very limited supply of oxygen, such as in this methane reaction:

Carbon black is used as a pigment in black inks; large amounts are also used in making automobile tires.

Charcoal is formed when wood is heated strongly in the absence of air. Charcoal has an open structure, giving it an enormous surface area per unit mass. "Activated charcoal," a pulverized form of charcoal whose surface is cleaned by heating with steam, is widely used to adsorb molecules. It is used in filters to remove offensive odors from air and colored or bad-tasting impurities from water.

Oxides of Carbon

Carbon forms two principal oxides: carbon monoxide (CO) and carbon dioxide (CO₂). *Carbon monoxide* is formed when carbon or hydrocarbons are burned in a limited supply of oxygen:

CO is a colorless, odorless, tasteless gas that is toxic because it binds to hemoglobin in the blood and thus interfere with oxygen transport. Low-level poisoning results in headaches and drowsiness; high-level poisoning can cause death. Automobile engines produce carbon monoxide, which is a major air pollutant.

Carbon monoxide is unusual in that it has a nonbonding pair of electrons on carbon: $\text{:C}\equiv\text{O:}$. It is isoelectronic with N₂, so you might expect CO to be equally unreactive. Moreover, both substances have high bond energies (1072 kJ/mol for C≡O and 941 kJ/mol for N≡N). Because of the lower nuclear charge on carbon (compared with either N or O), however, the carbon nonbonding pair is not held as strongly as that on N or O. Consequently, CO is better able to function as a Lewis base than is N₂; for example, CO can coordinate its nonbonding pair to the iron of hemoglobin, displacing O₂, but N₂ cannot. In addition, CO forms a variety of covalent compounds, known as metal carbonyls, with transition metals. Ni(CO)₄, for example, is a volatile, toxic compound formed by warming metallic nickel in the presence of CO. The formation of metal carbonyls is the first step in the transition-metal catalysis of a variety of reactions of CO.

Carbon monoxide has several commercial uses. Because it burns readily, forming CO₂, it is employed as a fuel:

Carbon monoxide is an important reducing agent, widely used in metallurgical operations to reduce metal oxides, such as the iron oxides:

Carbon dioxide is produced when carbon-containing substances are burned in excess oxygen, such as in this reaction involving ethanol:

CHEMISTRY PUT TO WORK

Carbon Fibers and Composites

The properties of graphite are anisotropic; that is, they differ in different directions through the solid. Along the carbon planes, graphite possesses great strength because of the number and strength of the carbon-carbon bonds in this direction. The bonds between planes are relatively weak, however, making graphite weak in that direction.

Fibers of graphite can be prepared in which the carbon planes are aligned to varying extents parallel to the fiber axis. These fibers are lightweight (density of about 2 g/cm^3) and chemically quite unreactive. The oriented fibers are made by first slowly pyrolyzing (decomposing by action of heat) organic fibers at about 150°C to 300°C . These fibers are then heated to about 2500°C to graphitize them (convert amorphous carbon to graphite). Stretching the fiber during pyrolysis helps orient the graphite planes parallel to the fiber axis. More amorphous carbon fibers are formed by pyrolysis of organic fibers at lower temperatures (1200°C to 400°C). These amorphous materials, commonly called *carbon fibers*, are the type most often used in commercial materials.

Composite materials that take advantage of the strength, stability, and low density of carbon fibers are widely used. Composites are combinations of two or more materials. These materials are present as separate phases and are combined to form structures that take advantage of certain desirable properties of each component. In carbon composites the graphite fibers are often woven into a fabric that is embedded in a matrix that binds them into a solid structure. The

fibers transmit loads evenly throughout the matrix. The finished composite is thus stronger than any one of its components.

Carbon composite materials are used widely in a number of applications, including high-performance graphite sports equipment such as tennis racquets, golf clubs, and bicycle wheels (▼ FIGURE 22.31). Heat-resistant composites are required for many aerospace applications, where carbon composites now find wide use.

▲ FIGURE 22.31 Carbon composites in commercial products.

It is also produced when many carbonates are heated:

Large quantities of CO_2 are obtained as a by-product of the fermentation of sugar during the production of ethanol:

In the laboratory, CO_2 can be produced by the action of acids on carbonates (► FIGURE 22.32):

Carbon dioxide is a colorless, odorless gas. It is a minor component of Earth's atmosphere but a major contributor to the greenhouse effect. ∞ (Section 18.2) Although it is not toxic, high concentrations of CO_2 increase respiration rate and can cause suffocation. It is readily liquefied by compression. When cooled at atmospheric pressure, however, CO_2 forms a solid rather than liquefying. The solid sublimates at atmospheric pressure at -78°C . This property makes solid CO_2 , known as dry ice, valuable as a refrigerant. About half of the CO_2 consumed annually is used for refrigeration. The other major use of CO_2 is in the production of carbonated beverages. Large quantities are also used to manufacture *washing soda* ($\text{Na}_2\text{CO}_3 \cdot 10 \text{H}_2\text{O}$), used to precipitate metal ions that interfere with the cleansing action of soap, and *baking soda* (NaHCO_3). Baking soda is so named because this reaction occurs during baking:

▲ FIGURE 22.32 CO_2 formation from the reaction between an acid and calcium carbonate in rock.

The $\text{H}^+(\text{aq})$ is provided by vinegar, sour milk, or the hydrolysis of certain salts. The bubbles of CO_2 that form are trapped in the baking dough, causing it to rise.

GIVE IT SOME THOUGHT

Yeast are living organisms that make bread rise in the absence of baking soda and acid. What must the yeast be producing to make bread rise?

Carbonic Acid and Carbonates

Carbon dioxide is moderately soluble in H_2O at atmospheric pressure. The resulting solution is moderately acidic because of the formation of carbonic acid (H_2CO_3):

Carbonic acid is a weak diprotic acid. Its acidic character causes carbonated beverages to have a sharp, slightly acidic taste.

Although carbonic acid cannot be isolated, hydrogen carbonates (bicarbonates) and carbonates can be obtained by neutralizing carbonic acid solutions. Partial neutralization produces HCO_3^- , and complete neutralization gives CO_3^{2-} . The HCO_3^- ion is a stronger base than acid ($K_b = 2.3 \times 10^{-8}$; $K_a = 5.6 \times 10^{-11}$). The carbonate ion is much more strongly basic ($K_b = 1.8 \times 10^{-4}$).

The principal carbonate minerals are calcite (CaCO_3), magnesite (MgCO_3), dolomite [$\text{MgCa}(\text{CO}_3)_2$], and siderite (FeCO_3). Calcite is the principal mineral in limestone and the main constituent of marble, chalk, pearls, coral reefs, and the shells of marine animals such as clams and oysters. Although CaCO_3 has low solubility in pure water, it dissolves readily in acidic solutions with evolution of CO_2 :

Because water containing CO_2 is slightly acidic (Equation 22.67), CaCO_3 dissolves slowly in this medium:

This reaction occurs when surface waters move underground through limestone deposits. It is the principal way Ca^{2+} enters groundwater, producing “hard water.” If the limestone deposit is deep enough underground, dissolution of the limestone produces a cave.

One of the most important reactions of CaCO_3 is its decomposition into CaO and CO_2 at elevated temperatures (Equation 22.63). About 2×10^{10} kg (20 million tons) of calcium oxide, known as lime or quicklime, is produced in the United States annually. Because calcium oxide reacts with water to form $\text{Ca}(\text{OH})_2$, it is an important commercial base. It is also important in making mortar, the mixture of sand, water, and CaO used to bind bricks, blocks, or rocks together. Calcium oxide reacts with water and CO_2 to form CaCO_3 , which binds the sand in the mortar:

Carbides

The binary compounds of carbon with metals, metalloids, and certain nonmetals are called **carbides**. The more active metals form *ionic carbides*, and the most common of these contain the *acetylide* ion (C_2^{2-}). This ion is isoelectronic with N_2 , and its Lewis structure, $[\text{:C}\equiv\text{C:}]^{2-}$, has a carbon–carbon triple bond. The most important ionic carbide is calcium carbide (CaC_2), produced by the reduction of CaO with carbon at high temperature:

The carbide ion is a very strong base that reacts with water to form acetylene ($\text{H}-\text{C}\equiv\text{C}-\text{H}$):

Calcium carbide is therefore a convenient solid source of acetylene, which is used in welding (Figure 22.13).

Interstitial carbides are formed by many transition metals. The carbon atoms occupy open spaces (interstices) between the metal atoms in a manner analogous to the interstitial hydrides (Section 22.2). This process generally makes the metal harder. Tungsten carbide, for example, is very hard and very heat-resistant and, thus, used to make cutting tools.

Covalent carbides are formed by boron and silicon. Silicon carbide (SiC), known as Carborundum®, is used as an abrasive and in cutting tools. Almost as hard as diamond, SiC has a diamondlike structure with alternating Si and C atoms.

Other Inorganic Compounds of Carbon

Hydrogen cyanide, HCN , is an extremely toxic gas that famously has the odor of bitter almonds. It is produced by the reaction of a cyanide salt, such as NaCN , with an acid. Aqueous solutions of HCN are known as hydrocyanic acid. Neutralization with a base produces cyanide salts, which are used in the manufacture of several plastics, including nylon and Orlon®. The CN^- ion forms stable complexes with most transition metals. [∞ \(Section 17.5\)](#)

Carbon disulfide, CS_2 , is an important industrial solvent for waxes, greases, celluloses, and other nonpolar substances. It is a colorless, volatile liquid (bp 46.3°C). The vapor is very poisonous and highly flammable.

GIVE IT SOME THOUGHT

Based on what you know of their physical properties, does CS_2 have stronger intermolecular forces than CO_2 ? Explain.

22.10 THE OTHER GROUP 4A ELEMENTS: Si, Ge, Sn, AND Pb

The trend from nonmetallic to metallic character as we go down a family is strikingly evident in group 4A. Carbon is a nonmetal; silicon and germanium are metalloids; tin and lead are metals. In this section we consider a few general characteristics of group 4A and then look more thoroughly at silicon.

General Characteristics of the Group 4A Elements

The group 4A elements possess the outer-shell electron configuration ns^2np^2 . The electronegativities of the elements are generally low ([▼ TABLE 22.8](#)); carbides that formally contain C^{4-} ions are observed only in the case of a few compounds of carbon with very active metals. Formation of $4+$ ions by electron loss is not observed for any of these elements; the ionization energies are too high. The $+2$ oxidation state is found in the

▲ FIGURE 22.33 Zone-refining apparatus for production of ultrapure silicon.

chemistry of germanium, tin, and lead, however, and it is the principal oxidation state for lead. The vast majority of the compounds of the group 4A elements are covalently bonded. Carbon, except in highly unusual examples, forms a maximum of four bonds. The other members of the family are able to form more than four bonds. (Section 8.7)

Table 22.8 shows that the strength of a bond between two atoms of a given element decreases as we go down group 4A. Carbon–carbon bonds are quite strong. Carbon, therefore, has a striking ability to form compounds in which carbon atoms are bonded to one another in extended chains and rings, which accounts for the large number of organic compounds that exist. Other elements can form chains and rings, but these bonds are far less important in the chemistries of these other elements. The Si—Si bond strength (226 kJ/mol), for example, is much lower than the Si—O bond strength (386 kJ/mol). As a result, the chemistry of silicon is dominated by the formation of Si—O bonds, and Si—Si bonds play a minor role in silicon chemistry.

Occurrence and Preparation of Silicon

Silicon is the second most abundant element, after oxygen, in Earth's crust. It occurs in SiO₂ and in an enormous variety of silicate minerals. The element is obtained by the reduction of molten silicon dioxide with carbon at high temperature:

Elemental silicon has a diamond-type structure. Crystalline silicon is a gray metallic-looking solid that melts at 1410 °C. The element is a semiconductor, as we saw in Chapters 7 and 12, and is used to make solar cells and transistors for computer chips. To be used as a semiconductor, it must be extremely pure, possessing less than 10⁻⁷% (1 ppb) impurities. One method of purification is to treat the element with Cl₂ to form SiCl₄, a volatile liquid that is purified by fractional distillation and then converted back to elemental silicon by reduction with H₂:

The process known as *zone refining* can further purify the element (◀ FIGURE 22.33). As a heated coil is passed slowly along a silicon rod, a narrow band of the element is melted. As the molten section is swept slowly along the length of the rod, the impurities concentrate in this section, following it to the end of the rod. The purified top portion of the rod crystallizes as 99.99999999% pure silicon.

Silicates

Silicon dioxide and other compounds that contain silicon and oxygen make up over 90% of Earth's crust. In **silicates**, a silicon atom is surrounded by four oxygens and silicon is found in its most common oxidation state, +4. The orthosilicate ion, SiO₄⁴⁻, is found in very few silicate minerals, but we can view it as the “building block” for many mineral structures. As ► FIGURE 22.34 shows, adjacent tetrahedra are linked by a common oxygen atom. Two tetrahedra joined in this way, called the *disilicate* ion, contain two Si atoms and seven O atoms. Silicon and oxygen are in the +4 and -2 oxidation states, respectively, in all silicates, so the overall charge of any silicate ion must be consistent with these oxidation states. Thus, the charge on Si₂O₇ is (2)(+4) + (7)(-2) = -6; it is the Si₂O₇⁶⁻ ion.

In most silicate minerals, silicate tetrahedra are linked together to form chains, sheets, or three-dimensional structures. We can connect two vertices of each tetrahedron to two other tetrahedra, for example, leading to an infinite chain with an ...O—Si—O—Si... backbone. As Figure 22.34(b) shows, this chain can be viewed as repeating units of the Si₂O₆⁴⁻ ion or, in terms of its simplest formula, SiO₃²⁻. The mineral *enstatite* (MgSiO₃) consists of rows of single-strand silicate chains with Mg²⁺ ions between the strands to balance charge.

In Figure 22.34(c) each silicate tetrahedron is linked to three others, forming an infinite sheet structure. The simplest formula of this sheet is Si₂O₅²⁻. The mineral *talc*, also known as talcum powder, has the formula Mg₃(Si₂O₅)₂(OH)₂ and is based on this sheet structure. The Mg²⁺ and OH⁻ ions lie between the silicate sheets. The slippery feel of talcum powder is due to the silicate sheets sliding relative to one another.

▲ **FIGURE 22.34** Silicate chains and sheets.

Many minerals are based on silicates, and many are useful as clays, ceramics, and other materials. Some silicates, however, have harmful effects on human health, the best-known example being *asbestos*, a general term applied to a group of fibrous silicate minerals. The structure of these minerals is either chains of silicate tetrahedra or sheets formed into rolls. The result is that the minerals have a fibrous character (► **FIGURE 22.35**). Asbestos minerals were once widely used as thermal insulation, especially in high-temperature applications, because of the great chemical stability of the silicate structure. In addition, the fibers can be woven into asbestos cloth, which was used for fireproof curtains and other applications. However, the fibrous structure of asbestos minerals poses a health risk because the fibers readily penetrate soft tissues, such as the lungs, where they can cause diseases, including cancer. The use of asbestos as a common building material has therefore been discontinued.

When all four vertices of each SiO_4 tetrahedron are linked to other tetrahedra, the structure extends in three dimensions. This linking of the tetrahedra forms quartz (SiO_2). Because the structure is locked together in a three-dimensional array much like diamond ∞ (Section 12.7) quartz is harder than strand- or sheet-type silicates.

▲ **FIGURE 22.35** Serpentine asbestos.

SAMPLE EXERCISE 22.9 Determining an Empirical Formula

The mineral *chrysotile* is a noncarcinogenic asbestos mineral that is based on the sheet structure shown in Figure 22.34(c). In addition to silicate tetrahedra, the mineral contains Mg^{2+} and OH^- ions. Analysis of the mineral shows that there are 1.5 Mg atoms per Si atom. What is the empirical formula for chrysotile?

SOLUTION

Analyze A mineral is described that has a sheet silicate structure with Mg^{2+} and OH^- ions to balance charge and 1.5 Mg for each 1 Si. We are asked to write the empirical formula for the mineral.

Plan As shown in Figure 22.34(c), the silicate sheet structure is based on the $\text{Si}_2\text{O}_5^{2-}$ ion. We first add Mg^{2+} to give the proper Mg:Si ratio. We then add OH^- ions to obtain a neutral compound.

Solve The observation that the Mg:Si ratio equals 1.5 is consistent with three Mg^{2+} ions per $\text{Si}_2\text{O}_5^{2-}$ ion. The addition of three Mg^{2+} ions would make $\text{Mg}_3(\text{Si}_2\text{O}_5)^{4+}$. In order to achieve charge balance in the mineral, there must be four OH^- ions per $\text{Si}_2\text{O}_5^{2-}$ ion. Thus, the formula of chrysotile is $\text{Mg}_3(\text{Si}_2\text{O}_5)(\text{OH})_4$. Since this is not reducible to a simpler formula, this is the empirical formula.

PRACTICE EXERCISE

The cyclosilicate ion consists of three silicate tetrahedra linked together in a ring. The ion contains three Si atoms and nine O atoms. What is the overall charge on the ion?

Answer: 6⁻

Glass

Quartz melts at approximately 1600 °C, forming a tacky liquid. In the course of melting, many silicon–oxygen bonds are broken. When the liquid cools rapidly, silicon–oxygen bonds are re-formed before the atoms are able to arrange themselves in a regular fashion. An amorphous solid, known as quartz glass or silica glass, results. Many substances can be added to SiO₂ to cause it to melt at a lower temperature. The common **glass** used in windows and bottles, known as soda-lime glass, contains CaO and Na₂O in addition to SiO₂ from sand. The CaO and Na₂O are produced by heating two inexpensive chemicals, limestone (CaCO₃) and soda ash (Na₂CO₃), which decompose at high temperatures:

Other substances can be added to soda-lime glass to produce color or to change the properties of the glass in various ways. The addition of CoO, for example, produces the deep blue color of “cobalt glass.” Replacing Na₂O with K₂O results in a harder glass that has a higher melting point. Replacing CaO with PbO results in a denser “lead crystal” glass with a higher refractive index. Lead crystal is used for decorative glassware; the higher refractive index gives this glass a particularly sparkling appearance. Addition of nonmetal oxides, such as B₂O₃ and P₄O₁₀, which form network structures related to the silicates, also changes the properties of the glass. Adding B₂O₃ creates a “borosilicate” glass with a higher melting point and a greater ability to withstand temperature changes. Such glasses, sold commercially under trade names such as Pyrex[®] and Kimax[®], are used where resistance to thermal shock is important, such as in laboratory glassware or coffeemakers.

Silicones

Silicones consist of O—Si—O chains in which the remaining bonding positions on each silicon are occupied by organic groups such as CH₃:

Depending on chain length and degree of cross-linking, silicones can be either oils or rubber-like materials. Silicones are nontoxic and have good stability toward heat, light, oxygen, and water. They are used commercially in a wide variety of products, including lubricants, car polishes, sealants, and gaskets. They are also used for waterproofing fabrics. When applied to a fabric, the oxygen atoms form hydrogen bonds with the molecules on the surface of the fabric. The hydrophobic (water-repelling) organic groups of the silicone are then left pointing away from the surface as a barrier.

GIVE IT SOME THOUGHT

Distinguish among the substances silicon, silica, and silicone.

22.11 BORON

Boron is the only group 3A element that can be considered nonmetallic and thus is our final element in this chapter. The element has an extended network structure with a melting point (2300 °C) that is intermediate between the melting points of carbon (3550 °C) and silicon (1410 °C). The electron configuration of boron is $[\text{He}]2s^22p^1$.

In the family of compounds called **boranes**, the molecules contain only boron and hydrogen. The simplest borane is BH_3 . This molecule contains only six valence electrons and is therefore an exception to the octet rule. As a result, BH_3 reacts with itself to form *diborane* (B_2H_6). This reaction can be viewed as a Lewis acid–base reaction in which one B—H bonding pair of electrons in each BH_3 molecule is donated to the other. As a result, diborane is an unusual molecule in which hydrogen atoms form a bridge between two B atoms (► **FIGURE 22.36**). Such hydrogens, called *bridging hydrogens*, exhibit interesting chemical reactivity, which you may learn about in a more advanced chemistry course.

Sharing hydrogen atoms between the two boron atoms compensates somewhat for the deficiency in valence electrons around each boron. Nevertheless, diborane is an extremely reactive molecule, spontaneously flammable in air in a highly exothermic reaction:

Boron and hydrogen form a series of anions called *borane anions*. Salts of the borohydride ion (BH_4^-) are widely used as reducing agents. For example, sodium borohydride (NaBH_4) is a commonly used reducing agent for certain organic compounds.

▲ GIVE IT SOME THOUGHT

Recall that the hydride ion is H^- . What is the oxidation state of boron in sodium borohydride?

The only important oxide of boron is boric oxide (B_2O_3). This substance is the anhydride of boric acid, which we may write as H_3BO_3 or $\text{B}(\text{OH})_3$. Boric acid is so weak an acid ($K_a = 5.8 \times 10^{-10}$) that solutions of H_3BO_3 are used as an eyewash. Upon heating, boric acid loses water by a condensation reaction similar to that described for phosphorus in Section 22.8:

The diprotic acid $\text{H}_2\text{B}_4\text{O}_7$ is tetraboric acid. The hydrated sodium salt $\text{Na}_2\text{B}_4\text{O}_7 \cdot 10 \text{H}_2\text{O}$, called borax, occurs in dry lake deposits in California and can also be prepared from other borate minerals. Solutions of borax are alkaline, and the substance is used in various laundry and cleaning products.

SAMPLE INTEGRATIVE EXERCISE Putting Concepts Together

The interhalogen compound BrF_3 is a volatile, straw-colored liquid. The compound exhibits appreciable electrical conductivity because of autoionization (“solv” refers to BrF_3 as the solvent):

(a) What are the molecular structures of the BrF_2^+ and BrF_4^- ions? (b) The electrical conductivity of BrF_3 decreases with increasing temperature. Is the autoionization process exothermic or endothermic? (c) One chemical characteristic of BrF_3 is that it acts as a Lewis acid toward fluoride ions. What do we expect will happen when KBr is dissolved in BrF_3 ?

SOLUTION

(a) The BrF_2^+ ion has $7 + 2(7) - 1 = 20$ valence-shell electrons. The Lewis structure for the ion is

3A	
5	B
13	Al
31	Ga
49	In
81	Tl

▲ **FIGURE 22.36** The structure of diborane (B_2H_6).

Because there are four electron domains around the central Br atom, the resulting electron domain geometry is tetrahedral. ∞ (Section 9.2) Because bonding pairs of electrons occupy two of these domains, the molecular geometry is nonlinear:

The BrF_4^- ion has $7 + 4(7) + 1 = 36$ electrons, leading to the Lewis structure

Because there are six electron domains around the central Br atom in this ion, the geometry is octahedral. The two nonbonding pairs of electrons are located opposite each other on the octahedron, leading to a square-planar molecular geometry:

(b) The observation that conductivity decreases as temperature increases indicates that there are fewer ions present in the solution at the higher temperature. Thus, increasing the temperature causes the equilibrium to shift to the left. According to Le Châtelier's principle, this shift indicates that the reaction is exothermic as it proceeds from left to right. ∞ (Section 15.7)

(c) A Lewis acid is an electron-pair acceptor. ∞ (Section 16.11) The fluoride ion has four valence-shell electron pairs and can act as a Lewis base (an electron-pair donor). Thus, we can envision the following reaction occurring:

CHAPTER SUMMARY AND KEY TERMS

INTRODUCTION AND SECTION 22.1 The periodic table is useful for organizing and remembering the descriptive chemistry of the elements. Among elements of a given group, size increases with increasing atomic number, and electronegativity and ionization energy decrease. Nonmetallic character parallels electronegativity, so the most nonmetallic elements are found in the upper right portion of the periodic table.

Among the nonmetallic elements, the first member of each group differs dramatically from the other members; it forms a maximum of four bonds to other atoms and exhibits a much greater tendency to form π bonds than the heavier elements in its group.

Because O_2 and H_2O are abundant in our world, we focus on two important and general reaction types as we discuss the nonmetals: oxidation by O_2 and proton-transfer reactions involving H_2O or aqueous solutions.

SECTION 22.2 Hydrogen has three isotopes: **protium** (${}^1\text{H}$), **deuterium** (${}^2\text{H}$), and **tritium** (${}^3\text{H}$). Hydrogen is not a member of any particular periodic group, although it is usually placed above lithium. The hydrogen atom can either lose an electron, forming H^+ , or gain one, forming H^- (the hydride ion). Because the H—H bond is relatively strong, H_2 is fairly unreactive unless activated by heat or a catalyst. Hydrogen forms a very strong bond to oxygen, so the reactions of H_2 with oxygen-containing compounds usually lead to the formation of H_2O . Because the bonds in CO and CO_2 are even stronger than the O—H bond, the reaction of H_2O with carbon or certain organic compounds leads to the formation of H_2 . The $\text{H}^+(\text{aq})$ ion is able to oxidize many metals, forming $\text{H}_2(\text{g})$. The electrolysis of water also forms $\text{H}_2(\text{g})$.

The binary compounds of hydrogen are of three general types: **ionic hydrides** (formed by active metals), **metallic hydrides** (formed

by transition metals), and **molecular hydrides** (formed by non-metals). The ionic hydrides contain the H^- ion; because this ion is extremely basic, ionic hydrides react with H_2O to form H_2 and OH^- .

SECTIONS 22.3 AND 22.4 The noble gases (group 8A) exhibit a very limited chemical reactivity because of the exceptional stability of their electron configurations. The xenon fluorides and oxides and KrF_2 are the best-established compounds of the noble gases.

The halogens (group 7A) occur as diatomic molecules. All except fluorine exhibit oxidation states varying from -1 to $+7$. Fluorine is the most electronegative element, so it is restricted to the oxidation states 0 and -1 . The oxidizing power of the element (the tendency to form the -1 oxidation state) decreases as we proceed down the group. The hydrogen halides are among the most useful compounds of these elements; these gases dissolve in water to form the hydrohalic acids, such as $\text{HCl}(aq)$. Hydrofluoric acid reacts with **silica**. The **interhalogens** are compounds formed between two different halogen elements. Chlorine, bromine, and iodine form a series of oxyacids, in which the halogen atom is in a positive oxidation state. These compounds and their associated oxyanions are strong oxidizing agents.

SECTIONS 22.5 AND 22.6 Oxygen has two allotropes, O_2 and O_3 (ozone). Ozone is unstable compared to O_2 , and it is a stronger oxidizing agent than O_2 . Most reactions of O_2 lead to oxides, compounds in which oxygen is in the -2 oxidation state. The soluble oxides of non-metals generally produce acidic aqueous solutions; they are called **acidic anhydrides** or **acidic oxides**. In contrast, soluble metal oxides produce basic solutions and are called **basic anhydrides** or **basic oxides**. Many metal oxides that are insoluble in water dissolve in acid, accompanied by the formation of H_2O . Peroxides contain $\text{O}-\text{O}$ bonds and oxygen in the -1 oxidation state. Peroxides are unstable, decomposing to O_2 and oxides. In such reactions peroxides are simultaneously oxidized and reduced, a process called **disproportionation**. Superoxides contain the O_2^- ion in which oxygen is in the $-\frac{1}{2}$ oxidation state.

Sulfur is the most important of the other group 6A elements. It has several allotropic forms; the most stable one at room temperature consists of S_8 rings. Sulfur forms two oxides, SO_2 and SO_3 , and both are important atmospheric pollutants. Sulfur trioxide is the anhydride of sulfuric acid, the most important sulfur compound and the most-produced industrial chemical. Sulfuric acid is a strong acid and a good dehydrating agent. Sulfur forms several oxyanions as well, including the SO_3^{2-} (sulfite), SO_4^{2-} (sulfate), and $\text{S}_2\text{O}_3^{2-}$ (thiosulfate) ions. Sulfur is found combined with many metals as a sulfide, in which sulfur is in the -2 oxidation state. These compounds often react with acids to form hydrogen sulfide (H_2S), which smells like rotten eggs.

SECTIONS 22.7 AND 22.8 Nitrogen is found in the atmosphere as N_2 molecules. Molecular nitrogen is chemically very stable because of the strong $\text{N}\equiv\text{N}$ bond. Molecular nitrogen can be converted into

ammonia via the Haber process. Once the ammonia is made, it can be converted into a variety of different compounds that exhibit nitrogen oxidation states ranging from -3 to $+5$. The most important industrial conversion of ammonia is the **Ostwald process**, in which ammonia is oxidized to nitric acid (HNO_3). Nitrogen has three important oxides: nitrous oxide (N_2O), nitric oxide (NO), and nitrogen dioxide (NO_2). Nitrous acid (HNO_2) is a weak acid; its conjugate base is the nitrite ion (NO_2^-). Another important nitrogen compound is hydrazine (N_2H_4).

Phosphorus is the most important of the remaining group 5A elements. It occurs in nature as phosphate minerals. Phosphorus has several allotropes, including white phosphorus, which consists of P_4 tetrahedra. In reaction with the halogens, phosphorus forms trihalides PX_3 and pentahalides PX_5 . These compounds undergo hydrolysis to produce an oxyacid of phosphorus and HX . Phosphorus forms two oxides, P_4O_6 and P_4O_{10} . Their corresponding acids, phosphorous acid and phosphoric acid, undergo condensation reactions when heated. Phosphorus compounds are important in biochemistry and as fertilizers.

SECTIONS 22.9 AND 22.10 The allotropes of carbon include diamond, graphite, fullerenes, carbon nanotubes, and graphene. Amorphous forms of graphite include **charcoal** and **carbon black**. Carbon forms two common oxides, CO and CO_2 . Aqueous solutions of CO_2 produce the weak diprotic acid carbonic acid (H_2CO_3), which is the parent acid of hydrogen carbonate and carbonate salts. Binary compounds of carbon are called **carbides**. Carbides may be ionic, interstitial, or covalent. Calcium carbide (CaC_2) contains the strongly basic acetylide ion (C_2^{2-}), which reacts with water to form acetylene. Other important inorganic carbon compounds include hydrogen cyanide (HCN) and carbon disulfide (CS_2).

The other group 4A elements show great diversity in physical and chemical properties. Silicon, the second most abundant element, is a semiconductor. It reacts with Cl_2 to form SiCl_4 , a liquid at room temperature, a reaction that is used to help purify silicon from its native minerals. Silicon forms strong $\text{Si}-\text{O}$ bonds and therefore occurs in a variety of silicate minerals. Silica is SiO_2 ; **silicates** consist of SiO_4 tetrahedra, linked together at their vertices to form chains, sheets, or three-dimensional structures. The most common three-dimensional silicate is quartz (SiO_2). **Glass** is an amorphous (noncrystalline) form of SiO_2 . Silicones contain $\text{O}-\text{Si}-\text{O}$ chains with organic groups bonded to the Si atoms. Like silicon, germanium is a metalloid; tin and lead are metallic.

SECTION 22.11 Boron is the only group 3A element that is a non-metal. It forms a variety of compounds with hydrogen called boron hydrides, or **boranes**. Diborane (B_2H_6) has an unusual structure with two hydrogen atoms that bridge between the two boron atoms. Boranes react with oxygen to form boric oxide (B_2O_3), in which boron is in the $+3$ oxidation state. Boric oxide is the anhydride of boric acid (H_3BO_3). Boric acid readily undergoes condensation reactions.

KEY SKILLS

- Be able to use periodic trends to explain the basic differences between the elements of a group or period (Section 22.1).
- Explain the ways in which the first element in a group differs from subsequent elements in the group (Section 22.1).
- Be able to determine electron configurations, oxidation numbers, and molecular shapes of elements and compounds (Sections 22.2–22.11).
- Know the sources of the common nonmetals, how they are obtained, and how they are used (Sections 22.2–22.11).
- Understand how phosphoric and phosphorous acids undergo condensation reactions (Section 22.8).
- Explain how the bonding and structures of silicates relate to their chemical formulas and properties (Section 22.10).

EXERCISES

VISUALIZING CONCEPTS

- 22.1 (a) One of these structures is a stable compound; the other is not. Identify the stable compound, and explain why it is stable. Explain why the other compound is not stable. (b) What is the geometry around the central atoms of the stable compound? [Section 22.1]

- 22.2 (a) Identify the *type* of chemical reaction represented by the following diagram. (b) Place appropriate charges on the species on both sides of the equation. (c) Write the chemical equation for the reaction. [Section 22.1]

- 22.3 Which of the following species (there may be more than one) is/are likely to have the structure shown here: (a) XeF_4 , (b) BrF_4^+ , (c) SiF_4 , (d) TeCl_4 , (e) HClO_4 ? (The colors do not reflect atom identities.) [Sections 22.3, 22.4, 22.6, and 22.10]

- 22.4 You have two glass bottles, one containing oxygen and one filled with ozone. How could you determine which one is which? [Section 22.5]
- 22.5 Write the molecular formula and Lewis structure for each of the following oxides of nitrogen: [Section 22.7]

- 22.6 Which property of the group 6A elements might be the one depicted in the graph shown here: (a) electronegativity, (b) first ionization energy, (c) density, (d) X—X single-bond enthalpy, (e) electron affinity? Explain your answer. [Sections 22.5 and 22.6]

- 22.7 The atomic and ionic radii of the first three group 6A elements are

Element	Atomic radius (Å)	Ionic radius (Å)
O	0.73	1.40
S	1.03	1.84
Se	1.17	1.98

- (a) Explain why the atomic radius increases in moving downward in the group. (b) Explain why the ionic radii are larger than the atomic radii. (c) Which of the three anions would you expect to be the strongest base in water? Explain. [Sections 22.5 and 22.6]

- 22.8 Which property of the third-row nonmetallic elements might be the one depicted in the graph on the next page: (a) first ionization energy, (b) atomic radius, (c) electronegativity, (d) melting point, (e) X—X single-bond enthalpy? Explain both

your choice and why the other choices would not be correct. [Sections 22.3, 22.4, 22.6, 22.8, and 22.10]

22.9 Which of the following compounds would you expect to be the most generally reactive, and why? [Section 22.8]

22.10 (a) Draw the Lewis structures for at least four species that have the general formula

where X and Y may be the same or different, and n may have a value from +1 to -2. (b) Which of the compounds is likely to be the strongest Brønsted base? Explain. [Sections 22.1, 22.7, and 22.9]

PERIODIC TRENDS AND CHEMICAL REACTIONS (section 22.1)

22.11 Identify each of the following elements as a metal, nonmetal, or metalloid: (a) phosphorus, (b) strontium, (c) manganese, (d) selenium, (e) sodium, (f) krypton.

22.12 Identify each of the following elements as a metal, nonmetal, or metalloid: (a) gallium, (b) molybdenum, (c) tellurium, (d) arsenic, (e) xenon, (f) ruthenium.

22.13 Consider the elements O, Ba, Co, Be, Br, and Se. From this list select the element that (a) is most electronegative, (b) exhibits a maximum oxidation state of +7, (c) loses an electron most readily, (d) forms π bonds most readily, (e) is a transition metal, (f) is a liquid at room temperature and pressure.

22.14 Consider the elements Li, K, Cl, C, Ne, and Ar. From this list select the element that (a) is most electronegative, (b) has the greatest metallic character, (c) most readily forms a positive ion, (d) has the smallest atomic radius, (e) forms π bonds most readily, (f) has multiple allotropes.

22.15 Explain the following observations: (a) The highest fluoride compound formed by nitrogen is NF_3 , whereas phosphorus readily forms PF_5 . (b) Although CO is a well-known compound, SiO does not exist under ordinary conditions. (c) AsH_3 is a stronger reducing agent than NH_3 .

22.16 Explain the following observations: (a) HNO_3 is a stronger oxidizing agent than H_3PO_4 . (b) Silicon can form an ion with six fluorine atoms, SiF_6^{2-} , whereas carbon is able to bond to a maximum of four, CF_4 . (c) There are three compounds formed by carbon and hydrogen that contain two carbon atoms each (C_2H_2 , C_2H_4 , and C_2H_6), whereas silicon forms only one analogous compound (Si_2H_6).

22.17 Complete and balance the following equations:

22.18 Complete and balance the following equations:

HYDROGEN, THE NOBLE GASES, AND THE HALOGENS (sections 22.2, 22.3, 22.4)

22.19 (a) Give the names and chemical symbols for the three isotopes of hydrogen. (b) List the isotopes in order of decreasing natural abundance. (c) Which hydrogen isotope is radioactive? (d) Write the nuclear equation for the radioactive decay of this isotope.

22.20 Are the physical properties of H_2O different from D_2O ? Explain.

22.21 Give a reason why hydrogen might be placed along with the group 1A elements of the periodic table.

22.22 What does hydrogen have in common with the halogens? Explain.

22.23 Write a balanced equation for the preparation of H_2 using (a) Mg and an acid, (b) carbon and steam, (c) methane and steam.

22.24 List (a) three commercial means of producing H_2 , (b) three industrial uses of H_2 .

22.25 Complete and balance the following equations:

22.26 Write balanced equations for each of the following reactions (some of these are analogous to reactions shown in the chapter). (a) Aluminum metal reacts with acids to form hydrogen gas. (b) Steam reacts with magnesium metal to give magnesium oxide and hydrogen. (c) Manganese(IV) oxide is reduced to manganese(II) oxide by hydrogen gas. (d) Calcium hydride reacts with water to generate hydrogen gas.

22.27 Identify the following hydrides as ionic, metallic, or molecular: (a) BaH_2 , (b) H_2Te , (c) $\text{TiH}_{1.7}$.

- 22.28** Identify the following hydrides as ionic, metallic, or molecular: (a) B_2H_6 , (b) RbH , (c) $Th_4H_{1.5}$.
- 22.29** Describe two characteristics of hydrogen that are favorable for its use as a general energy source in vehicles.
- 22.30** The H_2/O_2 fuel cell converts elemental hydrogen and oxygen into water, producing, theoretically, 1.23 V of energy. What is the most sustainable way to obtain hydrogen to run a large number of fuel cells? Explain.
- 22.31** Why does xenon form stable compounds with fluorine, whereas argon does not?
- 22.32** A friend tells you that the “neon” in neon signs is a compound of neon and aluminum. Can your friend be correct? Explain.
- 22.33** Write the chemical formula for each of the following, and indicate the oxidation state of the halogen or noble-gas atom in each: (a) calcium hypobromite, (b) bromic acid, (c) xenon trioxide, (d) perchlorate ion, (e) iodous acid, (f) iodine pentafluoride.
- 22.34** Write the chemical formula for each of the following compounds, and indicate the oxidation state of the halogen or noble-gas atom in each: (a) chlorate ion, (b) hydroiodic acid, (c) iodine trichloride, (d) sodium hypochlorite, (e) perchloric acid, (f) xenon tetrafluoride.
- 22.35** Name the following compounds and assign oxidation states to the halogens in them: (a) $Fe(ClO_3)_3$, (b) $HClO_2$, (c) XeF_6 , (d) BrF_5 , (e) $XeOF_4$, (f) HIO_3 .
- 22.36** Name the following compounds and assign oxidation states to the halogens in them: (a) $KClO_3$, (b) $Ca(IO_3)_2$, (c) $AlCl_3$, (d) $HBrO_3$, (e) H_5IO_6 , (f) XeF_4 .
- 22.37** Explain each of the following observations: (a) At room temperature I_2 is a solid, Br_2 is a liquid, and Cl_2 and F_2 are both gases. (b) F_2 cannot be prepared by electrolytic oxidation of aqueous F^- solutions. (c) The boiling point of HF is much higher than those of the other hydrogen halides. (d) The halogens decrease in oxidizing power in the order $F_2 > Cl_2 > Br_2 > I_2$.
- 22.38** Explain the following observations: (a) For a given oxidation state, the acid strength of the oxyacid in aqueous solution decreases in the order chlorine > bromine > iodine. (b) Hydrofluoric acid cannot be stored in glass bottles. (c) HI cannot be prepared by treating NaI with sulfuric acid. (d) The interhalogen ICl_3 is known, but $BrCl_3$ is not.

OXYGEN AND THE OTHER GROUP 6A ELEMENTS (sections 22.5 and 22.6)

- 22.39** Write balanced equations for each of the following reactions. (a) When mercury(II) oxide is heated, it decomposes to form O_2 and mercury metal. (b) When copper(II) nitrate is heated strongly, it decomposes to form copper(II) oxide, nitrogen dioxide, and oxygen. (c) Lead(II) sulfide, $PbS(s)$, reacts with ozone to form $PbSO_4(s)$ and $O_2(g)$. (d) When heated in air, $ZnS(s)$ is converted to ZnO . (e) Potassium peroxide reacts with $CO_2(g)$ to give potassium carbonate and O_2 . (f) Oxygen is converted to ozone in the upper atmosphere.
- 22.40** Complete and balance the following equations:
- (a) $CaO(s) + H_2O(l) \longrightarrow$
 (b) $Al_2O_3(s) + H^+(aq) \longrightarrow$
 (c) $Na_2O_2(s) + H_2O(l) \longrightarrow$
 (d) $N_2O_3(g) + H_2O(l) \longrightarrow$
 (e) $KO_2(s) + H_2O(l) \longrightarrow$
 (f) $NO(g) + O_3(g) \longrightarrow$
- 22.41** Predict whether each of the following oxides is acidic, basic, amphoteric, or neutral: (a) NO_2 , (b) CO_2 , (c) Al_2O_3 , (d) CaO .
- 22.42** Select the more acidic member of each of the following pairs: (a) Mn_2O_7 and MnO_2 , (b) SnO and SnO_2 , (c) SO_2 and SO_3 , (d) SiO_2 and SO_2 , (e) Ga_2O_3 and In_2O_3 , (f) SO_2 and SeO_2 .
- 22.43** Write the chemical formula for each of the following compounds, and indicate the oxidation state of the group 6A element in each: (a) selenous acid, (b) potassium hydrogen sulfite, (c) hydrogen telluride, (d) carbon disulfide, (e) calcium sulfate, (f) cadmium sulfide, (g) zinc telluride.
- 22.44** Write the chemical formula for each of the following compounds, and indicate the oxidation state of the group 6A element in each: (a) sulfur tetrachloride, (b) selenium trioxide, (c) sodium thiosulfate, (d) hydrogen sulfide, (e) sulfuric acid, (f) sulfur dioxide, (g) mercury telluride.
- 22.45** In aqueous solution, hydrogen sulfide reduces (a) Fe^{3+} to Fe^{2+} , (b) Br_2 to Br^- , (c) MnO_4^- to Mn^{2+} , (d) HNO_3 to NO_2 . In all cases, under appropriate conditions, the product is elemental sulfur. Write a balanced net ionic equation for each reaction.
- 22.46** An aqueous solution of SO_2 reduces (a) aqueous $KMnO_4$ to $MnSO_4(aq)$, (b) acidic aqueous $K_2Cr_2O_7$ to aqueous Cr^{3+} , (c) aqueous $Hg_2(NO_3)_2$ to mercury metal. Write balanced equations for these reactions.
- 22.47** Write the Lewis structure for each of the following species, and indicate the structure of each: (a) SeO_3^{2-} ; (b) S_2Cl_2 ; (c) chlorosulfonic acid, HSO_3Cl (chlorine is bonded to sulfur).
- 22.48** The SF_5^- ion is formed when $SF_4(g)$ reacts with fluoride salts containing large cations, such as $CsF(s)$. Draw the Lewis structures for SF_4 and SF_5^- , and predict the molecular structure of each.
- 22.49** Write a balanced equation for each of the following reactions: (a) Sulfur dioxide reacts with water. (b) Solid zinc sulfide reacts with hydrochloric acid. (c) Elemental sulfur reacts with sulfite ion to form thiosulfate. (d) Sulfur trioxide is dissolved in sulfuric acid.
- 22.50** Write a balanced equation for each of the following reactions. (You may have to guess at one or more of the reaction products, but you should be able to make a reasonable guess, based on your study of this chapter.) (a) Hydrogen selenide can be prepared by reaction of an aqueous acid solution on aluminum selenide. (b) Sodium thiosulfate is used to remove excess Cl_2 from chlorine-bleached fabrics. The thiosulfate ion forms SO_4^{2-} and elemental sulfur, while Cl_2 is reduced to Cl^- .

NITROGEN AND THE OTHER GROUP 5A ELEMENTS (sections 22.7 and 22.8)

- 22.51** Write the chemical formula for each of the following compounds, and indicate the oxidation state of nitrogen in each: (a) sodium nitrite, (b) ammonia, (c) nitrous oxide, (d) sodium cyanide, (e) nitric acid, (f) nitrogen dioxide, (g) nitrogen, (h) boron nitride.
- 22.52** Write the chemical formula for each of the following compounds, and indicate the oxidation state of nitrogen in each: (a) nitric oxide, (b) hydrazine, (c) potassium cyanide, (d) sodium nitrite, (e) ammonium chloride, (f) lithium nitride.

- 22.53** Write the Lewis structure for each of the following species, describe its geometry, and indicate the oxidation state of the nitrogen: (a) HNO_2 , (b) N_3^- , (c) N_2H_5^+ , (d) NO_3^- .
- 22.54** Write the Lewis structure for each of the following species, describe its geometry, and indicate the oxidation state of the nitrogen: (a) NH_4^+ , (b) NO_2^- , (c) N_2O , (d) NO_2 .
- 22.55** Complete and balance the following equations:
 (a) $\text{Mg}_3\text{N}_2(\text{s}) + \text{H}_2\text{O}(\text{l}) \longrightarrow$
 (b) $\text{NO}(\text{g}) + \text{O}_2(\text{g}) \longrightarrow$
 (c) $\text{N}_2\text{O}_5(\text{g}) + \text{H}_2\text{O}(\text{l}) \longrightarrow$
 (d) $\text{NH}_3(\text{aq}) + \text{H}^+(\text{aq}) \longrightarrow$
 (e) $\text{N}_2\text{H}_4(\text{l}) + \text{O}_2(\text{g}) \longrightarrow$
- Which ones of these are redox reactions?
- 22.56** Write a balanced net ionic equation for each of the following reactions: (a) Dilute nitric acid reacts with zinc metal with formation of nitrous oxide. (b) Concentrated nitric acid reacts with sulfur with formation of nitrogen dioxide. (c) Concentrated nitric acid oxidizes sulfur dioxide with formation of nitric oxide. (d) Hydrazine is burned in excess fluorine gas, forming NF_3 . (e) Hydrazine reduces CrO_4^{2-} to $\text{Cr}(\text{OH})_4^-$ in base (hydrazine is oxidized to N_2).
- 22.57** Write complete balanced half-reactions for (a) oxidation of nitrous acid to nitrate ion in acidic solution, (b) oxidation of N_2 to N_2O in acidic solution.
- 22.58** Write complete balanced half-reactions for (a) reduction of nitrate ion to NO in acidic solution, (b) oxidation of HNO_2 to NO_2 in acidic solution.
- 22.59** Write a molecular formula for each compound, and indicate the oxidation state of the group 5A element in each formula:
- (a) phosphorous acid, (b) pyrophosphoric acid, (c) antimony trichloride, (d) magnesium arsenide, (e) diphosphorus pentoxide, (f) sodium phosphate.
- 22.60** Write a chemical formula for each compound or ion, and indicate the oxidation state of the group 5A element in each formula: (a) phosphate ion, (b) arsenous acid, (c) antimony(III) sulfide, (d) calcium dihydrogen phosphate, (e) potassium phosphide, (f) gallium arsenide.
- 22.61** Account for the following observations: (a) Phosphorus forms a pentachloride, but nitrogen does not. (b) H_3PO_2 is a monoprotic acid. (c) Phosphonium salts, such as PH_4Cl , can be formed under anhydrous conditions, but they can't be made in aqueous solution. (d) White phosphorus is more reactive than red phosphorus.
- 22.62** Account for the following observations: (a) H_3PO_3 is a diprotic acid. (b) Nitric acid is a strong acid, whereas phosphoric acid is weak. (c) Phosphate rock is ineffective as a phosphate fertilizer. (d) Phosphorus does not exist at room temperature as diatomic molecules, but nitrogen does. (e) Solutions of Na_3PO_4 are quite basic.
- 22.63** Write a balanced equation for each of the following reactions: (a) preparation of white phosphorus from calcium phosphate, (b) hydrolysis of PBr_3 , (c) reduction of PBr_3 to P_4 in the gas phase, using H_2 .
- 22.64** Write a balanced equation for each of the following reactions: (a) hydrolysis of PCl_5 , (b) dehydration of phosphoric acid (also called orthophosphoric acid) to form pyrophosphoric acid, (c) reaction of P_4O_{10} with water.

CARBON, THE OTHER GROUP 4A ELEMENTS, AND BORON (sections 22.9, 22.10, 22.11)

- 22.65** Give the chemical formula for (a) hydrocyanic acid, (b) nickel tetracarbonyl, (c) barium bicarbonate, (d) calcium acetylide (e) potassium carbonate.
- 22.66** Give the chemical formula for (a) carbonic acid, (b) sodium cyanide, (c) potassium hydrogen carbonate, (d) acetylene, (e) iron pentacarbonyl.
- 22.67** Complete and balance the following equations:
 (a) $\text{ZnCO}_3(\text{s}) \xrightarrow{\Delta}$
 (b) $\text{BaC}_2(\text{s}) + \text{H}_2\text{O}(\text{l}) \longrightarrow$
 (c) $\text{C}_2\text{H}_2(\text{g}) + \text{O}_2(\text{g}) \longrightarrow$
 (d) $\text{CS}_2(\text{g}) + \text{O}_2(\text{g}) \longrightarrow$
 (e) $\text{Ca}(\text{CN})_2(\text{s}) + \text{HBr}(\text{aq}) \longrightarrow$
- 22.68** Complete and balance the following equations:
 (a) $\text{CO}_2(\text{g}) + \text{OH}^-(\text{aq}) \longrightarrow$
 (b) $\text{NaHCO}_3(\text{s}) + \text{H}^+(\text{aq}) \longrightarrow$
 (c) $\text{CaO}(\text{s}) + \text{C}(\text{s}) \xrightarrow{\Delta}$
 (d) $\text{C}(\text{s}) + \text{H}_2\text{O}(\text{g}) \xrightarrow{\Delta}$
 (e) $\text{CuO}(\text{s}) + \text{CO}(\text{g}) \longrightarrow$
- 22.69** Write a balanced equation for each of the following reactions: (a) Hydrogen cyanide is formed commercially by passing a mixture of methane, ammonia, and air over a catalyst at 800°C . Water is a by-product of the reaction. (b) Baking soda reacts with acids to produce carbon dioxide gas. (c) When barium carbonate reacts in air with sulfur dioxide, barium sulfate and carbon dioxide form.
- 22.70** Write a balanced equation for each of the following reactions: (a) Burning magnesium metal in a carbon dioxide atmosphere reduces the CO_2 to carbon. (b) In photosynthesis, solar energy is used to produce glucose ($\text{C}_6\text{H}_{12}\text{O}_6$) and O_2 from carbon dioxide and water. (c) When carbonate salts dissolve in water, they produce basic solutions.
- 22.71** Write the formulas for the following compounds, and indicate the oxidation state of the group 4A element or of boron in each: (a) boric acid, (b) silicon tetrabromide, (c) lead(II) chloride, (d) sodium tetraborate decahydrate (borax), (e) boric oxide, (f) germanium dioxide.
- 22.72** Write the formulas for the following compounds, and indicate the oxidation state of the group 4A element or of boron in each: (a) silicon dioxide, (b) germanium tetrachloride, (c) sodium borohydride, (d) stannous chloride, (e) diborane, (f) boron trichloride.
- 22.73** Select the member of group 4A that best fits each description: (a) has the lowest first ionization energy, (b) is found in oxidation states ranging from -4 to $+4$, (c) is most abundant in Earth's crust.
- 22.74** Select the member of group 4A that best fits each description: (a) forms chains to the greatest extent, (b) forms the most basic oxide, (c) is a metalloid that can form $2+$ ions.
- 22.75** (a) What is the characteristic geometry about silicon in all silicate minerals? (b) Metasilicic acid has the empirical formula H_2SiO_3 . Which of the structures shown in Figure 22.34 would you expect metasilicic acid to have?

- 22.76 Speculate as to why carbon forms carbonate rather than silicate analogs.
- 22.77 (a) How does the structure of diborane (B_2H_6) differ from that of ethane (C_2H_6)? (b) Explain why diborane adopts the geometry that it does. (c) What is the significance of the statement that the hydrogen atoms in diborane are described as “hydridic”?

ADDITIONAL EXERCISES

- 22.79 In your own words, define the following terms: (a) allotrope, (b) disproportionation, (c) interhalogen, (d) acidic anhydride, (e) condensation reaction, (f) protium.
- 22.80 Although the ClO_4^- and IO_4^- ions have been known for a long time, BrO_4^- was not synthesized until 1965. The ion was synthesized by oxidizing the bromate ion with xenon difluoride, producing xenon, hydrofluoric acid, and the perbromate ion. (a) Write the balanced equation for this reaction. (b) What are the oxidation states of Br in the Br-containing species in this reaction?
- 22.81 Write a balanced equation for the reaction of each of the following compounds with water: (a) $SO_2(g)$, (b) $Cl_2O_7(g)$, (c) $Na_2O_2(s)$, (d) $BaC_2(s)$, (e) $RbO_2(s)$, (f) $Mg_3N_2(s)$, (g) $NaH(s)$.
- 22.82 What is the anhydride for each of the following acids: (a) H_2SO_4 , (b) $HClO_3$, (c) HNO_2 , (d) H_2CO_3 , (e) H_3PO_4 ?
- 22.83 Explain why SO_2 can be used as a reducing agent but SO_3 cannot.
- 22.84 A sulfuric acid plant produces a considerable amount of heat. This heat is used to generate electricity, which helps reduce operating costs. The synthesis of H_2SO_4 consists of three main chemical processes: (1) oxidation of S to SO_2 , (2) oxidation of SO_2 to SO_3 , (3) the dissolving of SO_3 in H_2SO_4 and its reaction with water to form H_2SO_4 . If the third process produces 130 kJ/mol, how much heat is produced in preparing a mole of H_2SO_4 from a mole of S? How much heat is produced in preparing 5000 pounds of H_2SO_4 ?

INTEGRATIVE EXERCISES

- [22.89] (a) How many grams of H_2 can be stored in 100.0 kg of the alloy FeTi if the hydride $FeTiH_2$ is formed? (b) What volume does this quantity of H_2 occupy at STP? (c) If this quantity of hydrogen was combusted in air to produce liquid water, how much energy could be produced?
- [22.90] Using the thermochemical data in Table 22.1 and Appendix C, calculate the average Xe—F bond enthalpies in XeF_2 , XeF_4 , and XeF_6 , respectively. What is the significance of the trend in these quantities?
- 22.91 Hydrogen gas has a higher fuel value than natural gas on a mass basis but not on a volume basis. Thus, hydrogen is not competitive with natural gas as a fuel transported long distances through pipelines. Calculate the heats of combustion of H_2 and CH_4 (the principal component of natural gas) (a) per mole of each, (b) per gram of each, (c) per cubic meter of each at STP. Assume $H_2O(l)$ as a product.
- 22.92 The solubility of Cl_2 in 100 g of water at STP is 310 cm^3 . Assume that this quantity of Cl_2 is dissolved and equilibrated as follows:

- 22.78 Write a balanced equation for each of the following reactions: (a) Diborane reacts with water to form boric acid and molecular hydrogen. (b) Upon heating, boric acid undergoes a condensation reaction to form tetraboric acid. (c) Boron oxide dissolves in water to give a solution of boric acid.
- 22.85 (a) What is the oxidation state of P in PO_4^{3-} and of N in NO_3^- ? (b) Why doesn't N form a stable NO_4^{3-} ion analogous to P?
- 22.86 (a) The P_4 , P_4O_6 , and P_4O_{10} molecules have a common structural feature of four P atoms arranged in a tetrahedron (Figures 22.27 and 22.28). Does this mean that the bonding between the P atoms is the same in all these cases? Explain. (b) Sodium trimetaphosphate ($Na_3P_3O_9$) and sodium tetrametaphosphate ($Na_4P_4O_{12}$) are used as water-softening agents. They contain cyclic $P_3O_9^{3-}$ and $P_4O_{12}^{4-}$ ions, respectively. Propose reasonable structures for these ions.
- 22.87 Ultrapure germanium, like silicon, is used in semiconductors. Germanium of “ordinary” purity is prepared by the high-temperature reduction of GeO_2 with carbon. The Ge is converted to $GeCl_4$ by treatment with Cl_2 and then purified by distillation; $GeCl_4$ is then hydrolyzed in water to GeO_2 and reduced to the elemental form with H_2 . The element is then zone refined. Write a balanced chemical equation for each of the chemical transformations in the course of forming ultrapure Ge from GeO_2 .
- 22.88 Hydrogen peroxide is capable of oxidizing (a) hydrazine to N_2 and H_2O , (b) SO_2 to SO_4^{2-} , (c) NO_2^- to NO_3^- , (d) $H_2S(g)$ to $S(s)$, (e) Fe^{2+} to Fe^{3+} . Write a balanced net ionic equation for each of these redox reactions.

(a) If the equilibrium constant for this reaction is 4.7×10^{-4} , calculate the equilibrium concentration of $HClO$ formed. (b) What is the pH of the final solution?

- [22.93] When ammonium perchlorate decomposes thermally, the products of the reaction are $N_2(g)$, $O_2(g)$, $H_2O(g)$, and $HCl(g)$. (a) Write a balanced equation for the reaction. [Hint: You might find it easier to use fractional coefficients for the products.] (b) Calculate the enthalpy change in the reaction per mole of NH_4ClO_4 . The standard enthalpy of formation of $NH_4ClO_4(s)$ is -295.8 kJ. (c) When $NH_4ClO_4(s)$ is employed in solid-fuel booster rockets, it is packed with powdered aluminum. Given the high temperature needed for $NH_4ClO_4(s)$ decomposition and what the products of the reaction are, what role does the aluminum play? (d) Calculate the volume of all the gases that would be produced at STP, assuming complete reaction of one pound of ammonium perchlorate.
- 22.94 The dissolved oxygen present in any highly pressurized, high-temperature steam boiler can be extremely corrosive to its metal parts. Hydrazine, which is completely miscible with water, can be added to remove oxygen by reacting with it to form nitrogen and water. (a) Write the balanced equation for

the reaction between gaseous hydrazine and oxygen. (b) Calculate the enthalpy change accompanying this reaction. (c) Oxygen in air dissolves in water to the extent of 9.1 ppm at 20 °C at sea level. How many grams of hydrazine are required to react with all the oxygen in 3.0×10^4 L (the volume of a small swimming pool) under these conditions?

- 22.95** One method proposed for removing SO_2 from the flue gases of power plants involves reaction with aqueous H_2S . Elemental sulfur is the product. (a) Write a balanced chemical equation for the reaction. (b) What volume of H_2S at 27 °C and 760 torr would be required to remove the SO_2 formed by burning 2.0 tons of coal containing 3.5% S by mass? (c) What mass of elemental sulfur is produced? Assume that all reactions are 100% efficient.
- 22.96** The maximum allowable concentration of $\text{H}_2\text{S}(\text{g})$ in air is 20 mg per kilogram of air (20 ppm by mass). How many grams of FeS would be required to react with hydrochloric acid to produce this concentration at 1.00 atm and 25 °C in an average room measuring 12 ft \times 20 ft \times 8 ft? (Under these conditions, the average molar mass of air is 29.0 g/mol.)
- 22.97** The standard heats of formation of $\text{H}_2\text{O}(\text{g})$, $\text{H}_2\text{S}(\text{g})$, $\text{H}_2\text{Se}(\text{g})$, and $\text{H}_2\text{Te}(\text{g})$ are -241.8 , -20.17 , $+29.7$, and $+99.6$ kJ/mol, respectively. The enthalpies necessary to convert the elements in their standard states to one mole of gaseous atoms are 248, 277, 227, and 197 kJ/mol of atoms for O, S, Se, and Te, respectively. The enthalpy for dissociation of H_2 is 436 kJ/mol. Calculate the average H—O, H—S, H—Se, and H—Te bond enthalpies, and comment on their trend.
- 22.98** Manganese silicide has the empirical formula MnSi and melts at 1280 °C. It is insoluble in water but does dissolve in aqueous HF. (a) What type of compound do you expect MnSi to be: metallic, molecular, covalent-network, or ionic? (b) Write a likely balanced chemical equation for the reaction of MnSi with concentrated aqueous HF.
- [22.99]** Chemists tried for a long time to make molecular compounds containing silicon–silicon double bonds; they finally succeed in 1981. The trick is having large, bulky R groups on the silicon atoms to make $\text{R}_2\text{Si}=\text{SiR}_2$ compounds. What experiments could you do to prove that a new compound has a silicon–silicon double bond rather than a silicon–silicon single bond?
- 22.100** Hydrazine has been employed as a reducing agent for metals. Using standard reduction potentials, predict whether the following metals can be reduced to the metallic state by hydrazine under standard conditions in acidic solution: (a) Fe^{2+} , (b) Sn^{2+} , (c) Cu^{2+} , (d) Ag^+ , (e) Cr^{3+} , (f) Co^{3+} .
- 22.101** Both dimethylhydrazine, $(\text{CH}_3)_2\text{NNH}_2$, and methylhydrazine, CH_3NHNH_2 , have been used as rocket fuels. When dinitrogen tetroxide (N_2O_4) is used as the oxidizer, the products are H_2O , CO_2 , and N_2 . If the thrust of the rocket depends on the volume of the products produced, which of the substituted hydrazines produces a greater thrust per gram total mass of oxidizer plus fuel? [Assume that both fuels generate the same temperature and that $\text{H}_2\text{O}(\text{g})$ is formed.]
- 22.102** Carbon forms an unusual unstable oxide of formula C_3O_2 , called carbon suboxide. Carbon suboxide is made by using P_2O_5 to dehydrate the dicarboxylic acid called malonic acid, which has the formula $\text{HOOC}-\text{CH}_2-\text{COOH}$. (a) Write a balanced reaction for the production of carbon suboxide from malonic acid. (b) How many grams of carbon suboxide could be made from 20.00 g of malonic acid? (c) Suggest a Lewis structure for C_3O_2 . (*Hint:* The Lewis structure of malonic acid suggests which atoms are connected to which.) (d) By using the information in Table 8.5, predict the C—C and C—O bond lengths in C_3O_2 . (e) Sketch the Lewis structure of a product that could result by the addition of 2 mol of H_2 to 1 mol of C_3O_2 .
- 22.103** Borazine, $(\text{BH})_3(\text{NH})_3$, is an analog of C_6H_6 , benzene. It can be prepared from the reaction of diborane with ammonia, with hydrogen as another product; or from lithium borohydride and ammonium chloride, with lithium chloride and hydrogen as the other products. (a) Write balanced chemical equations for the production of borazine using both synthetic methods. (b) Draw the Lewis dot structure of borazine. (c) How many grams of borazine can be prepared from 2.00 L of ammonia at STP, assuming diborane is in excess?
- 22.104** Throughout history, arsenic(III) oxide, known simply to the general public as “arsenic,” has been a poison favored by murderers: It is tasteless, colorless, can be easily added to food or drink, produces symptoms that are similar to several diseases, and until the mid-1800s, was undetectable in the body. James Marsh developed the famous “Marsh test” for arsenic that was instrumental in convicting the murderer in a famous poisoning case in France in 1840. The Marsh test relies on the reaction of arsenic(III) oxide in a sample with elemental zinc and sulfuric acid to produce arsine (an analog of ammonia), zinc sulfate, and water. Upon igniting the final mixture, arsine is oxidized to elemental arsenic, and if captured on a ceramic bowl, a characteristic silvery-black powder would appear. (a) Write the balanced chemical equations of the Marsh test. (b) Antimony is the only potential interferent, as it reacts similarly to arsenic and produces a similar silvery-black film; however, antimony does not dissolve in a solution of sodium hypochlorite, but arsenic does. Therefore, the completion of the Marsh test is to add a solution of sodium hypochlorite to the elemental arsenic and see if the silvery-black film dissolves. Write the balanced chemical equation for this final reaction. (c) Today, commercial kits for arsenic testing rely on a different reaction. The sample is reacted with hydrogen sulfide in the presence of hydrochloric acid; if arsenic is present, As_2S_3 , which is a bright yellow precipitate, forms. Write the balanced equation for this reaction.

WHAT'S AHEAD

23.1 THE TRANSITION METALS

We examine the physical properties, electron configurations, oxidation states, and magnetic properties of the *transition metals*.

23.2 TRANSITION-METAL COMPLEXES

We introduce the concepts of *metal complexes* and *ligands* and provide a brief history of the development of *coordination chemistry*.

23.3 COMMON LIGANDS IN COORDINATION CHEMISTRY

We examine some common geometries found in coordination complexes and how the geometries relate to *coordination numbers*.

23.4 NOMENCLATURE AND ISOMERISM IN COORDINATION CHEMISTRY

We introduce the nomenclature used for coordination compounds. We see that coordination compounds exhibit *isomerism*, in which two compounds have the same composition but different structures, and then look at two types: *structural isomers* and *stereoisomers*.

23

THIS STAINED GLASS WINDOW, representing chemistry, is in the Kalamazoo Public Library, Kalamazoo, Michigan.

23.5 COLOR AND MAGNETISM IN COORDINATION CHEMISTRY

We discuss color and magnetism in coordination compounds, emphasizing the visible portion of the electromagnetic spectrum and the notion of *complementary colors*. We then see that many transition-metal complexes are paramagnetic because they contain unpaired electrons.

23.6 CRYSTAL-FIELD THEORY

We explore how *crystal-field theory* allows us to explain some of the interesting spectral and magnetic properties of coordination compounds.

TRANSITION METALS AND COORDINATION CHEMISTRY

THE COLORS OF OUR WORLD ARE beautiful, but to a chemist they are also informative—providing insights into the structure and bonding of matter. Compounds of the transition metals constitute an important group of colored substances. Some of them are used in paint pigments; others produce the colors in

glass and precious gems. For example, the colors in the stained-glass artwork shown in the chapter-opening photograph are due mainly to transition-metal compounds. Why do these compounds have color, and why do the colors change as the ions or molecules bonded to the metal change? The chemistry we explore in this chapter will help us to answer these questions.

In earlier chapters we saw that metal ions can function as Lewis acids, forming covalent bonds with molecules and ions functioning as Lewis bases. ∞ (Section 16.11) We have encountered many ions and compounds that result from such interactions, such as $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$ and $[\text{Ag}(\text{NH}_3)_2]^+$ in Sections 16.11 and 17.5 and hemoglobin in

Section 13.6. In this chapter, we focus on the rich and important chemistry associated with such complex assemblies of metal ions surrounded by molecules and ions. Metal compounds of this kind are called *coordination compounds*, and the branch of chemistry that focuses on them is called *coordination chemistry*.

23.1 THE TRANSITION METALS

The part of the periodic table in which the *d* orbitals are being filled as we move left to right across a row is the home of the transition metals (◀ **FIGURE 23.1**). ∞ (Section 6.8)

3B	4B	5B	6B	7B	8B			1B	2B

▲ **FIGURE 23.1** The position of the transition metals in the periodic table. They are the B groups in periods 4, 5, and 6.

With some exceptions (e.g., platinum, gold), metallic elements are found in nature as solid inorganic compounds called **minerals**. Notice from ▼ **TABLE 23.1** that minerals are identified by common names rather than chemical names. These common names are usually based on the location where a mineral was discovered, the person who discovered it, or some physical characteristic such as color.

Most transition metals in minerals have oxidation states of +1, +2, or +3. To obtain a pure metal from its mineral, various chemical processes must be performed to reduce the metal to the 0 oxidation state. **Metallurgy** is the science and technology of extracting metals from their natural sources and preparing them for practical use. It usually involves several steps: (1) mining, that is, removing the relevant *ore* (a mixture of minerals) from the ground, (2) concentrating the ore or otherwise preparing it for further treatment, (3) reducing the ore to obtain the free metal, (4) purifying the metal, and (5) mixing it with other elements to modify its properties. This last process produces an *alloy*, a metallic material composed of two or more elements. ∞ (Section 12.3)

Physical Properties

Some physical properties of the period 4 (also known as “first-row”) transition metals are listed in ► **TABLE 23.2**. The properties of the heavier transition metals vary similarly across periods 5 and 6.

► **FIGURE 23.2** shows the atomic radius observed in close-packed metallic structures as a function of group number.* The trends seen in the graph are a result of two competing forces. On the one hand, increasing effective nuclear charge favors a decrease

TABLE 23.1 • Principal Mineral Sources of Some Transition Metals

Metal	Mineral	Mineral Composition
Chromium	Chromite	FeCr ₂ O ₄
Copper	Chalcocite	Cu ₂ S
	Chalcopyrite	CuFeS ₂
	Malachite	Cu ₂ CO ₃ (OH) ₂
Iron	Hematite	Fe ₂ O ₃
	Magnetite	Fe ₃ O ₄
Manganese	Pyrolusite	MnO ₂
Mercury	Cinnabar	HgS
Molybdenum	Molybdenite	MoS ₂
Titanium	Rutile	TiO ₂
	Ilmenite	FeTiO ₃
Zinc	Sphalerite	ZnS

*Note that the radii defined in this way, often referred to as metallic radii, differ somewhat from the bonding atomic radii defined in Section 7.3.

TABLE 23.2 • Properties of the Period 4 Transition Metals

in radius as we move left to right across each period. ∞ (Section 7.2) On the other hand, the metallic bonding strength increases until we reach the middle of each period and then decreases as we fill antibonding orbitals. ∞ (Section 12.4) As a general rule, a bond shortens as it becomes stronger. ∞ (Section 8.8) For groups 3B through 6B, these two effects work cooperatively and the result is a marked decrease in radius. In elements to the right of group 6B, the two effects counteract each other, reducing the decrease and eventually leading to an increase in radius.

GIVE IT SOME THOUGHT

Which element has the largest bonding atomic radius: Sc, Fe, or Au?

In general, atomic radii increase as we move down in a family in the periodic table because of the increasing principal quantum number of the outer-shell electrons. ∞ (Section 7.3) Note in Figure 23.2, however, that once we move beyond the group 3B elements, the period 5 and period 6 transition elements in a given family have virtually the same radii. In group 5B, for example, tantalum in period 6 has virtually the same radius as niobium in period 5. This interesting and important effect has its origin in the lanthanide series, elements 57 through 70. The filling of $4f$ orbitals through the lanthanide elements ∞ (Figure 6.31) causes a steady increase in the effective nuclear charge, producing a size decrease, called the **lanthanide contraction**, that just offsets the increase we expect as we go from period 5 transition metals to period 6. Thus, the period 5 and period 6 transition metals in each group have about the same radii all the way across the periodic table. Consequently, the period 5 and period 6 transition metals in a given group have similar chemical properties. For example, the chemical properties of the group 4B metals zirconium (period 5) and hafnium (period 6) are remarkably similar. These two metals always occur together in nature, and they are very difficult to separate.

Electron Configurations and Oxidation States

Transition metals owe their location in the periodic table to the filling of the d subshells, as you saw in Figure 6.31. Many of the chemical and physical properties of transition metals result from the unique characteristics of the d orbitals. For a given transition-metal atom, the valence $(n - 1)d$ orbitals are smaller than the corresponding valence ns and np orbitals. In quantum mechanical terms, the $(n - 1)d$ orbital wave functions drop off more rapidly as we move away from the nucleus than do the ns and np orbital wave functions. This characteristic feature of the d orbitals limits their interaction with orbitals on neighboring atoms, but not so much that they are insensitive to

▲ FIGURE 23.2 Radii of transition metals as a function of group number.

GO FIGURE

In which transition-metal ion of this group are the 3*d* orbitals completely filled?

► **FIGURE 23.3** Aqueous solutions of transition metal ions. Left to right: Co^{2+} , Ni^{2+} , Cu^{2+} , and Zn^{2+} . The counterion is nitrate in all cases.

surrounding atoms. As a result, electrons in these orbitals behave sometimes like valence electrons and sometimes like core electrons. The details depend on location in the periodic table and the atom's environment.

When transition metals are oxidized, they lose their outer *s* electrons before they lose electrons from the *d* subshell. ∞ (Section 7.4) The electron configuration of Fe is $[\text{Ar}]3d^64s^2$, for example, whereas that of Fe^{2+} is $[\text{Ar}]3d^6$. Formation of Fe^{3+} requires loss of one *3d* electron, giving $[\text{Ar}]3d^5$. Most transition-metal ions contain partially occupied *d* subshells, which are responsible in large part for three characteristics:

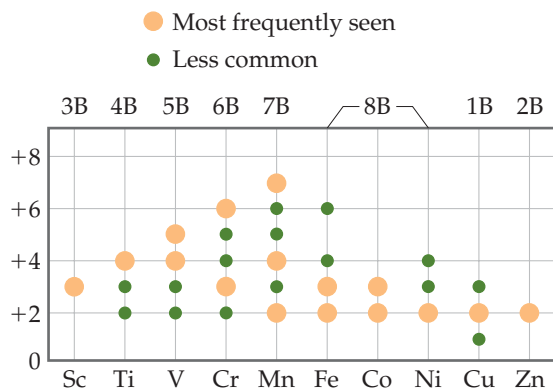

1. Transition metals often have more than one stable oxidation state.
2. Many transition-metal compounds are colored, as shown in ▲ FIGURE 23.3.
3. Transition metals and their compounds often exhibit magnetic properties.

◀ FIGURE 23.4 shows the common nonzero oxidation states for the period 4 transition metals. The +2 oxidation state, which is common for most transition metals, is due to the loss of the two outer *4s* electrons. This oxidation state is found for all these elements except Sc, where the 3+ ion with an [Ar] configuration is particularly stable.

Oxidation states above +2 are due to successive losses of *3d* electrons. From Sc through Mn the maximum oxidation state increases from +3 to +7, equaling in each case the total number of *4s* plus *3d* electrons in the atom. Thus, manganese has a maximum oxidation state of $2 + 5 = +7$. As we move to the right beyond Mn in Figure 23.4, the maximum oxidation state decreases. This decrease is due in part to the attraction of *d* orbital electrons to the nucleus, which increases faster than the attraction of the *s* orbital electrons to the nucleus as we move left to right across the periodic table. In other words, in each period the *d* electrons become more corelike as the atomic number increases. By the time we get to zinc, it is not possible to remove electrons from the *3d* orbitals through chemical oxidation.

GO FIGURE

Why does the maximum oxidation state increase linearly from Sc through Mn?

▲ **FIGURE 23.4** Nonzero oxidation states of the period 4 transition metals.

In the transition metals of periods 5 and 6, the increased size of the $4d$ and $5d$ orbitals makes it possible to attain maximum oxidation states as high as +8, which is achieved in RuO_4 and OsO_4 . In general, the maximum oxidation states are found only when the metals are combined with the most electronegative elements, especially O, F, and in some cases Cl.

GIVE IT SOME THOUGHT

Why doesn't Ti^{5+} exist?

Magnetism

The spin an electron possesses gives the electron a *magnetic moment*, a property that causes the electron to behave like a tiny magnet. In a *diamagnetic* solid, defined as one in which all the electrons in the solid are paired, the spin-up and spin-down electrons cancel one another. (Section 9.8) Diamagnetic substances are generally described as being nonmagnetic, but when a diamagnetic substance is placed in a magnetic field, the motions of the electrons cause the substance to be very weakly repelled by the magnet. In other words, these supposedly nonmagnetic substances do show some very faint magnetic character in the presence of a magnetic field.

A substance in which the atoms or ions have one or more unpaired electrons is *paramagnetic*. (Section 9.8) In a paramagnetic solid, the electrons on one atom or ion do not influence the unpaired electrons on neighboring atoms or ions. As a result, the magnetic moments on the atoms or ions are randomly oriented, as shown in ► FIGURE 23.5(a). When a paramagnetic substance is placed in a magnetic field, however, the magnetic moments tend to align parallel to one another, producing a net attractive interaction with the magnet. Thus, unlike a diamagnetic substance, which is weakly repulsed by a magnetic field, a paramagnetic substance is attracted to a magnetic field.

When you think of a magnet, you probably picture a simple iron magnet. Iron exhibits **ferromagnetism**, a form of magnetism much stronger than paramagnetism. Ferromagnetism arises when the unpaired electrons of the atoms or ions in a solid are influenced by the orientations of the electrons in neighboring atoms or ions. The most stable (lowest-energy) arrangement is when the spins of electrons on adjacent atoms or ions are aligned in the same direction, as in Figure 23.5(b). When a ferromagnetic solid is placed in a magnetic field, the electrons tend to align strongly in a direction parallel to the magnetic field. The attraction to the magnetic field that results may be as much as one million times stronger than that for a paramagnetic substance.

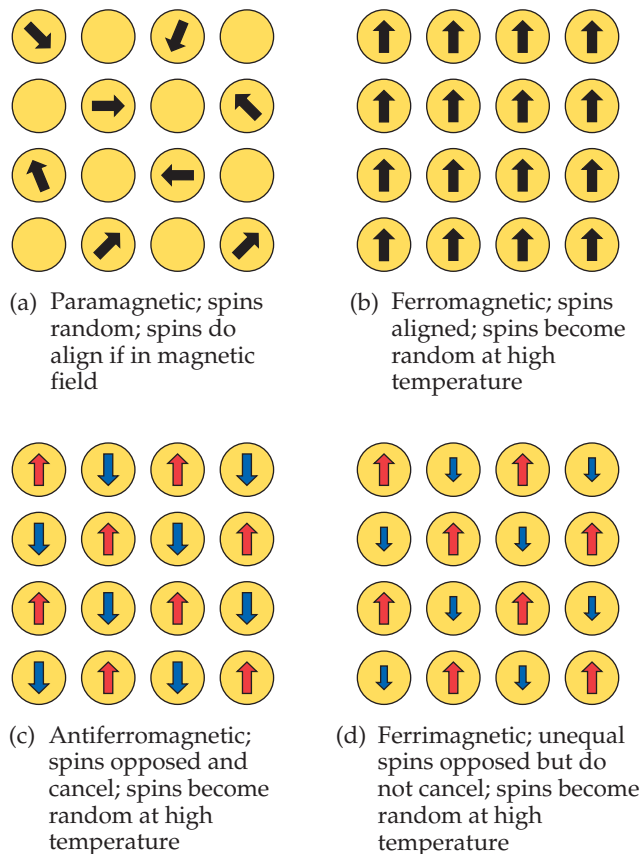

When a ferromagnet is removed from an external magnetic field, the interactions between the electrons cause the ferromagnetic substance to maintain a magnetic moment. We then refer to it as a *permanent magnet* (► FIGURE 23.6).

The only ferromagnetic transition metals are Fe, Co, and Ni, but many alloys also exhibit ferromagnetism, which is in some cases stronger than the ferromagnetism of the pure metals. Particularly powerful ferromagnetism is found in compounds containing both transition metals and lanthanide metals. Two of the most important examples are SmCo_5 and $\text{Nd}_2\text{Fe}_{14}\text{B}$.

Two additional types of magnetism involving ordered arrangements of unpaired electrons are depicted in Figure 23.5. In materials that exhibit **antiferromagnetism** [Figure 23.5(c)], the unpaired electrons on a given atom or ion align so that their spins are oriented in the direction opposite the spin direction on neighboring atoms.

GO FIGURE

Describe how the representation shown for the paramagnetic material would have to be changed if the material were placed in a magnetic field.

▲ FIGURE 23.5 The relative orientation of electron spins in various types of magnetic substances.

▲ FIGURE 23.6 A permanent magnet. Permanent magnets are made from ferromagnetic and ferrimagnetic materials.

This means that the spin-up and spin-down electrons cancel each other. Examples of antiferromagnetic substances are chromium metal, FeMn alloys, and such transition-metal oxides as Fe_2O_3 , LaFeO_3 , and MnO .

A substance that exhibits **ferrimagnetism** [Figure 23.5(d)] has both ferromagnetic and antiferromagnetic properties. Like an antiferromagnet, the unpaired electrons align so that the spins in adjacent atoms or ions point in opposite directions. However, unlike an antiferromagnet, the net magnetic moments of the spin-up electrons are not fully canceled by the spin-down electrons. This can happen because the magnetic centers have different numbers of unpaired electrons (NiMnO_3), because the number of magnetic sites aligned in one direction is larger than the number aligned in the other direction ($\text{Y}_3\text{Fe}_5\text{O}_{12}$), or because both these conditions apply (Fe_3O_4). Because the magnetic moments do not cancel, the properties of ferrimagnetic materials are similar to the properties of ferromagnetic materials.

GIVE IT SOME THOUGHT

How do you think spin-spin interactions of unpaired electrons on adjacent atoms in a substance are affected by the interatomic distance?

Ferromagnets, ferrimagnets, and antiferromagnets all become paramagnetic when heated above a critical temperature. This happens when the thermal energy is sufficient to overcome the forces determining the spin directions of the electrons. This temperature is called the *Curie temperature*, T_C , for ferromagnets and ferrimagnets and the *Néel temperature*, T_N , for antiferromagnets.

23.2 | TRANSITION-METAL COMPLEXES

The transition metals occur in many interesting and important molecular forms. Species that are assemblies of a central transition-metal ion bonded to a group of surrounding molecules or ions, such as $[\text{Ag}(\text{NH}_3)_2]^+$ and $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$, are called **metal complexes**, or merely *complexes*.^{*} If the complex carries a net charge, it is generally called a *complex ion*. ∞ (Section 17.5) Compounds that contain complexes are known as **coordination compounds**.

The molecules or ions that bond to the metal ion in a complex are known as **ligands** (from the Latin word *ligare*, “to bind”). There are two NH_3 ligands bonded to Ag^+ in the complex ion $[\text{Ag}(\text{NH}_3)_2]^+$, for instance, and six H_2O ligands bonded to Fe^{3+} in $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$. Each ligand functions as a Lewis base and so donates a pair of electrons to form the ligand–metal bond. ∞ (Section 16.11) Thus, every ligand has at least one unshared pair of valence electrons. Four of the most frequently encountered ligands,

illustrate that most ligands are either polar molecules or anions. In forming a complex, the ligands are said to *coordinate* to the metal.

GIVE IT SOME THOUGHT

Is the interaction between an ammonia ligand and a metal cation a Lewis acid–base interaction? If so, which species acts as the Lewis acid?

^{*}Most of the coordination compounds we examine in this chapter contain transition-metal ions, although ions of other metals can also form complexes.

TABLE 23.3 • Properties of Some Ammonia Complexes of Cobalt(III)

Original Formulation	Color	Ions per Formula Unit	“Free” Cl ⁻ Ions per Formula Unit	Modern Formulation
CoCl ₃ · 6 NH ₃	Orange	4	3	[Co(NH ₃) ₆]Cl ₃
CoCl ₃ · 5 NH ₃	Purple	3	2	[Co(NH ₃) ₅ Cl]Cl ₂
CoCl ₃ · 4 NH ₃	Green	2	1	<i>trans</i> -[Co(NH ₃) ₄ Cl ₂]Cl
CoCl ₃ · 4 NH ₃	Violet	2	1	<i>cis</i> -[Co(NH ₃) ₄ Cl ₂]Cl

The Development of Coordination Chemistry: Werner’s Theory

Because compounds of the transition metals are beautifully colored, the chemistry of these elements fascinated chemists even before the periodic table was introduced. During the late 1700s through the 1800s, the many coordination compounds that were isolated and studied had properties that were puzzling in light of the bonding theories prevailing at the time. ▲ TABLE 23.3, for example, lists a series of CoCl₃-NH₃ compounds that have strikingly different colors. Note that the third and fourth species have different colors even though the originally assigned formula was the same for both, CoCl₃ · 4 NH₃.

The modern formulations of the compounds in Table 23.3 are based on various lines of experimental evidence. For example, all four compounds are strong electrolytes ∞ (Section 4.1) but yield different numbers of ions when dissolved in water. Dissolving CoCl₃ · 6 NH₃ in water yields four ions per formula unit ([Co(NH₃)₆]³⁺ plus three Cl⁻ ions), whereas CoCl₃ · 5 NH₃ yields only three ions per formula unit ([Co(NH₃)₅Cl]²⁺ and two Cl⁻ ions). Furthermore, the reaction of the compounds with excess aqueous silver nitrate leads to the precipitation of different amounts of AgCl(s). When CoCl₃ · 6 NH₃ is treated with excess AgNO₃(aq), 3 mol of AgCl(s) are produced per mole of complex, which means all three Cl⁻ ions in the complex can react to form AgCl(s). By contrast, when CoCl₃ · 5 NH₃ is treated with excess AgNO₃(aq), only 2 mol of AgCl(s) precipitate per mole of complex, telling us that one of the Cl⁻ ions in the complex does not react. These results are summarized in Table 23.3.

In 1893 the Swiss chemist Alfred Werner (1866–1919) proposed a theory that successfully explained the observations in Table 23.3. In a theory that became the basis for understanding coordination chemistry, Werner proposed that any metal ion exhibits both a primary valence and a secondary valence. The *primary valence* is the oxidation state of the metal, which is +3 for the complexes in Table 23.3. ∞ (Section 4.4) The *secondary valence* is the number of atoms bonded to the metal ion, which is also called the **coordination number**. For these cobalt complexes, Werner deduced a coordination number of 6 with the ligands in an octahedral arrangement around the Co³⁺ ion.

Werner’s theory provided a beautiful explanation for the results in Table 23.3. The NH₃ molecules are ligands bonded to the Co³⁺ ion; if there are fewer than six NH₃ molecules, the remaining ligands are Cl⁻ ions. The central metal and the ligands bound to it constitute the **coordination sphere** of the complex.

In writing the chemical formula for a coordination compound, Werner suggested using square brackets to signify the makeup of the coordination sphere in any given compound. He therefore proposed that CoCl₃ · 6 NH₃ and CoCl₃ · 5 NH₃ are better written as [Co(NH₃)₆]Cl₃ and [Co(NH₃)₅Cl]Cl₂, respectively. He further proposed that the chloride ions that are part of the coordination sphere are bound so tightly that they do not dissociate when the complex is dissolved in water. Thus, dissolving [Co(NH₃)₅Cl]Cl₂ in water produces a [Co(NH₃)₅Cl]²⁺ ion and two Cl⁻ ions.

Werner’s ideas also explained why there are two forms of CoCl₃ · 4 NH₃. Using Werner’s postulates, we write the formula as [Co(NH₃)₄Cl₂]Cl. As shown in ► FIGURE 23.7, there are two ways to arrange the ligands in the [Co(NH₃)₄Cl₂]⁺ complex, called the *cis* and *trans* forms. In the *cis* form, the two chloride ligands occupy adjacent vertices

► **FIGURE 23.7** Isomers of $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^+$. The cis isomer is violet, and the trans isomer is green.

of the octahedral arrangement. In $\text{trans}-[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^+$ the two chlorides are opposite each other. It is this difference in positions of the Cl ligands that leads to two compounds, one violet and one green.

The insight Werner provided into the bonding in coordination compounds is even more remarkable when we realize that his theory predated Lewis's ideas of covalent bonding by more than 20 years! Because of his tremendous contributions to coordination chemistry, Werner was awarded the 1913 Nobel Prize in Chemistry.

SAMPLE EXERCISE 23.1 Identifying the Coordination Sphere of a Complex

Palladium(II) tends to form complexes with coordination number 4. A compound has the composition $\text{PdCl}_2 \cdot 3 \text{NH}_3$. (a) Write the formula for this compound that best shows the coordination structure. (b) When an aqueous solution of the compound is treated with excess $\text{AgNO}_3(\text{aq})$, how many moles of $\text{AgCl}(\text{s})$ are formed per mole of $\text{PdCl}_2 \cdot 3 \text{NH}_3$?

SOLUTION

Analyze We are given the coordination number of Pd(II) and a chemical formula indicating that the complex contains NH_3 and Cl^- . We are asked to determine (a) which ligands are attached to Pd(II) in the compound and (b) how the compound behaves toward AgNO_3 in aqueous solution.

Plan (a) Because of their charge, the Cl^- ions can be either in the coordination sphere, where they are bonded directly to the metal, or outside the coordination sphere, where they are bonded ionically to the complex. The electrically neutral NH_3 ligands must be in the coordination sphere, if we assume four ligands bonded to the Pd(II) ion. (b) Any chlorides in the coordination sphere do not precipitate as AgCl .

Solve

(a) By analogy to the ammonia complexes of cobalt(III) shown in Figure 23.7, we predict that the three NH_3 are ligands attached to the Pd(II) ion. The fourth ligand around Pd(II) is one chloride ion. The second chloride ion is not a ligand; it serves only as a *counterion* (a noncoordinating ion that balances charge) in the compound. We conclude that the formula showing the structure best is $[\text{Pd}(\text{NH}_3)_3\text{Cl}]\text{Cl}$.

(b) Because only the non-ligand Cl^- can react, we expect to produce 1 mol of $\text{AgCl}(\text{s})$ per mole of complex. The balanced equation is

This is a metathesis reaction ∞ (Section 4.2) in which one of the cations is the $[\text{Pd}(\text{NH}_3)_3\text{Cl}]^+$ complex ion.

PRACTICE EXERCISE

Predict the number of ions produced per formula unit in an aqueous solution of $\text{CoCl}_2 \cdot 6 \text{H}_2\text{O}$.

Answer: three: $[\text{Co}(\text{H}_2\text{O})_6]^{2+}$ and two Cl^-

The Metal–Ligand Bond

The bond between a ligand and a metal ion is a Lewis acid–base interaction. Because the ligands have available pairs of electrons, they can function as Lewis bases (electron-pair donors). Metal ions (particularly transition-metal ions) have empty valence orbitals, so they can act as Lewis acids (electron-pair acceptors). We can picture the bond between the metal ion and ligand as the result of their sharing a pair of electrons initially on the ligand:

The formation of metal–ligand bonds can markedly alter the properties we observe for the metal ion. A metal complex is a distinct chemical species that has physical and chemical properties different from those of the metal ion and ligands from which it is formed. As one example, **FIGURE 23.8** shows the color change that occurs when aqueous solutions of NCS^- (colorless) and Fe^{3+} (yellow) are mixed, forming $[\text{Fe}(\text{H}_2\text{O})_5\text{NCS}]^{2+}$.

Complex formation can also significantly change other properties of metal ions, such as their ease of oxidation or reduction. Silver ion, for example, is readily reduced in water,

but the $[\text{Ag}(\text{CN})_2]^-$ ion is not so easily reduced because complexation by CN^- ions stabilizes silver in the +1 oxidation state:

Hydrated metal ions are complexes in which the ligand is water. Thus, $\text{Fe}^{3+}(aq)$ consists largely of $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$. ∞ (Section 16.11) It is important to realize that

FIGURE 23.8 Reaction of $\text{Fe}^{3+}(aq)$ and $\text{NCS}^-(aq)$.

ligands can undergo reaction. For example, we saw in Figure 16.16 that a water molecule in $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}(\text{aq})$ can be deprotonated to yield $[\text{Fe}(\text{H}_2\text{O})_5\text{OH}]^{2+}(\text{aq})$ and $\text{H}^+(\text{aq})$. The iron ion retains its oxidation state; the coordinated hydroxide ligand, with a 1− charge, reduces the complex charge to 2+. Ligands can also be displaced from the coordination sphere by other ligands, if the incoming ligands bind more strongly to the metal ion than the original ones. For example, ligands such as NH_3 , NCS^- , and CN^- can replace H_2O in the coordination sphere of metal ions.

GIVE IT SOME THOUGHT

Write a balanced chemical equation for the reaction that causes the color change in Figure 23.8.

Charges, Coordination Numbers, and Geometries

The charge of a complex is the sum of the charges on the metal and on the ligands. In $[\text{Cu}(\text{NH}_3)_4]\text{SO}_4$ we can deduce the charge on the complex ion because we know that the charge of the sulfate ion is 2−. Because the compound is electrically neutral, the complex ion must have a 2+ charge, $[\text{Cu}(\text{NH}_3)_4]^{2+}$. We can then use the charge of the complex ion to deduce the oxidation number of copper. Because the NH_3 ligands are uncharged molecules, the oxidation number of copper must be +2:

SAMPLE EXERCISE 23.2 Determining the Oxidation Number of a Metal in a Complex

What is the oxidation number of the metal in $[\text{Rh}(\text{NH}_3)_5\text{Cl}](\text{NO}_3)_2$?

SOLUTION

Analyze We are given the chemical formula of a coordination compound and asked to determine the oxidation number of its metal atom.

Plan To determine the oxidation number of Rh, we need to figure out what charges are contributed by the other groups. The overall charge is zero, so the oxidation number of the metal must balance the charge due to the rest of the compound.

Solve The NO_3 group is the nitrate anion, which has a 1− charge. The NH_3 ligands carry zero charge, and the Cl is a coordinated chloride ion, which has a 1− charge. The sum of all the charges must be zero:

The oxidation number of rhodium, x , must therefore be +3.

PRACTICE EXERCISE

What is the charge of the complex formed by a platinum(II) metal ion surrounded by two ammonia molecules and two bromide ions?

Answer: zero

SAMPLE EXERCISE 23.3 Determining the Formula of a Complex Ion

A complex ion contains a chromium(III) bound to four water molecules and to two chloride ions. What is the formula and charge of this ion?

SOLUTION

Analyze We are given a metal, its oxidation number, and the number of ligands of each kind in a complex ion containing the metal, and we are asked to write the chemical formula and charge of the ion.

Plan We write the metal first, then the ligands. We can use the charges of the metal ion and ligands to determine the charge of the complex ion. The oxidation state of the metal is +3, water has no charge, and chloride has a 1− charge.

Solve

The charge on the ion is 1+, $[\text{Cr}(\text{H}_2\text{O})_4\text{Cl}_2]^+$.

PRACTICE EXERCISE

Write the formula for the complex described in the Practice Exercise accompanying Sample Exercise 23.2.

Answer: $[\text{Pt}(\text{NH}_3)_2\text{Br}_2]$

Recall that the number of atoms directly bonded to the metal atom in a complex is the *coordination number* of the complex. Thus, the silver ion in $[\text{Ag}(\text{NH}_3)_2]^+$ has a coordination number of 2, and the cobalt ion has a coordination number of 6 in all four complexes in Table 23.3.

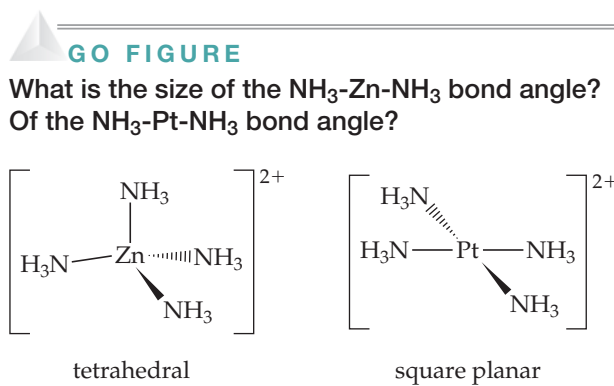

Some metal ions have only one observed coordination number. The coordination number of chromium(III) and cobalt(III) is invariably 6, for example, and that of platinum(II) is always 4. For most metals, however, the coordination number is different for different ligands. In these complexes, the most common coordination numbers are 4 and 6.

The coordination number of a metal ion is often influenced by the relative sizes of the metal ion and the ligands. As the ligand gets larger, fewer of them can coordinate to the metal ion. Thus, iron(III) is able to coordinate to six fluorides in $[\text{FeF}_6]^{3-}$ but to only four chlorides in $[\text{FeCl}_4]^-$.

Ligands that transfer substantial negative charge to the metal also produce reduced coordination numbers. For example, six ammonia molecules can coordinate to nickel(II), forming $[\text{Ni}(\text{NH}_3)_6]^{2+}$, but only four cyanide ions can coordinate to this ion, forming $[\text{Ni}(\text{CN})_4]^{2-}$.

Complexes in which the coordination number is 4 have two common geometries—tetrahedral and square planar (► FIGURE 23.9). The tetrahedral geometry is the more common of the two and is especially common among nontransition metals. The square-planar geometry is characteristic of transition-metal ions with eight *d* electrons in the valence shell, such as platinum(II) and gold(III).

The vast majority of complexes in which the coordination number is 6 have an octahedral geometry. The octahedron, which has eight faces and six vertices, is often represented as a square with ligands above and below the plane, as in ▼ FIGURE 23.10. Recall, however, that all six vertices on an octahedron are geometrically equivalent.

▲ FIGURE 23.9 In complexes having coordination number 4, the molecular geometry can be tetrahedral or square planar.

◀ FIGURE 23.10 In complexes having coordination number 6, the molecular geometry is almost always octahedral. Two ways to draw octahedral geometry are shown.

∞ (Section 9.2) The octahedron can also be thought of as two square pyramids that share the same square base.

▲ GIVE IT SOME THOUGHT

What are the geometries most commonly associated with

- coordination number 4,
- coordination number 6?

23.3 COMMON LIGANDS IN COORDINATION CHEMISTRY

The ligand atom that binds to the central metal ion in a coordination complex is called the **donor atom** of the ligand. Ligands having only one donor atom are called **monodentate ligands** (from the Latin, meaning “one-toothed”). These ligands are able to occupy only one site in a coordination sphere. Ligands having two donor atoms are **bidentate ligands** (“two-toothed”), and those having three or more donor atoms are **polydentate ligands** (“many-toothed”). In both bidentate and polydentate species, the multiple donor atoms can simultaneously bond to the metal ion, thereby occupying two or more sites in a coordination sphere. ▼ TABLE 23.4 gives examples of all three types of ligands.

Because they appear to grasp the metal between two or more donor atoms, bidentate and polydentate ligands are also known as **chelating agents** (pronounced “KEE-lay-ting”; from the Greek *chele*, “claw”).

TABLE 23.4 • Some Common Ligands

Ligand Type	Examples
Monodentate	$\text{H}_2\ddot{\text{O}}:$ Water $:\ddot{\text{F}}:^-$ Fluoride ion $[:\text{C}\equiv\text{N}:]^-$ Cyanide ion $[:\ddot{\text{O}}-\text{H}]^-$ Hydroxide ion $:\text{NH}_3$ Ammonia $:\ddot{\text{Cl}}:^-$ Chloride ion $[\ddot{\text{S}}=\text{C}=\ddot{\text{N}}:]^-$ Thiocyanate ion $[\ddot{\text{O}}-\text{N}=\ddot{\text{O}}:]^-$ Nitrite ion <small>↑ or ↓</small> <small>↑ or ↓</small>
Bidentate	 Ethylenediamine (en) Bipyridine (bipy or bpy) <i>Ortho</i> -phenanthroline (<i>o</i> -phen) Oxalate ion Carbonate ion
Polydentate	 Diethylenetriamine Triphosphate ion
	 Ethylenediaminetetraacetate ion (EDTA ⁴⁻)

◀ **FIGURE 23.11** The $[\text{Co}(\text{en})_3]^{3+}$ ion. The ligand is ethylenediamine.

One common chelating agent is the bidentate ligand *ethylenediamine*, en:

in which each donor nitrogen atom has one nonbonding electron pair. These donor atoms are sufficiently far apart to allow both of them to bond to the metal ion in adjacent positions. The $[\text{Co}(\text{en})_3]^{3+}$ complex ion, which contains three ethylenediamine ligands in the octahedral coordination sphere of cobalt(III), is shown in **▲ FIGURE 23.11**. Notice that in the image on the right the en is written in a shorthand notation as two nitrogen atoms connected by an arc.

The ethylenediaminetetraacetate ion, $[\text{EDTA}]^{4-}$, is an important polydentate ligand that has six donor atoms. It can wrap around a metal ion using all six donor atoms, as shown in **► FIGURE 23.12**, although it sometimes binds to a metal using only five of its donor atoms.

In general, the complexes formed by chelating ligands (that is, bidentate and polydentate ligands) are more stable than the complexes formed by related monodentate ligands. The equilibrium formation constants for $[\text{Ni}(\text{NH}_3)_6]^{2+}$ and $[\text{Ni}(\text{en})_3]^{2+}$ illustrate this observation:

Although the donor atom is nitrogen in both instances, $[\text{Ni}(\text{en})_3]^{2+}$ has a formation constant that is more than 10^8 times larger than that of $[\text{Ni}(\text{NH}_3)_6]^{2+}$. This trend of generally larger formation constants for bidentate and polydentate ligands, known as the **chelate effect**, is examined in the “A Closer Look” essay on page 977.

Chelating agents are often used to prevent one or more of the customary reactions of a metal ion without removing the ion from solution. For example, a metal ion that interferes with a chemical analysis can often be complexed and its interference thereby removed. In a sense, the chelating agent hides the metal ion. For this reason, scientists sometimes refer to these ligands as *sequestering agents*.

Phosphate ligands, such as sodium tripolyphosphate, $\text{Na}_5[\text{OPO}_2\text{OPO}_2\text{OPO}_3]$, are used to sequester Ca^{2+} and Mg^{2+} ions in hard water so that these ions cannot interfere with the action of soap or detergents.

Chelating agents are used in many prepared foods, such as salad dressings and frozen desserts, to complex trace metal ions that catalyze decomposition reactions. Chelating agents are used in medicine to remove toxic heavy metal ions that have been ingested, such as Hg^{2+} , Pb^{2+} , and Cd^{2+} . One method of treating lead poisoning, for example, is to administer $\text{Na}_2[\text{Ca}(\text{EDTA})]$. The EDTA chelates the lead, allowing it to be removed from the body via urine.

▲ **FIGURE 23.12** The EDTA^{4-} ligand (top) and the complex ion $[\text{Co}(\text{EDTA})]^{-}$ (bottom). The ligand is the polydentate ethylenediaminetetraacetate ion, which has six donor atoms, two N and four O.

GIVE IT SOME THOUGHT

Cobalt(III) has a coordination number of 6 in all its complexes. Is the carbonate ion a monodentate or bidentate ligand in the $[\text{Co}(\text{NH}_3)_4\text{CO}_3]^+$ ion?

Metals and Chelates in Living Systems

Ten of the 29 elements known to be necessary for human life are transition metals. ∞ (Section 2.7, “Chemistry and Life: Elements Required by Living Organisms”) These ten elements—V, Cr, Mn, Fe, Co, Ni, Cu, Zn, Mo, and Cd—form complexes with a variety of groups present in biological systems.

Although our bodies require only small quantities of metals, deficiencies can lead to serious illness. A deficiency of manganese, for example, can lead to convulsive disorders. Some epilepsy patients have been helped by the addition of manganese to their diets.

Among the most important chelating agents in nature are those derived from the *porphine* molecule (◀ **FIGURE 23.13**). This molecule can coordinate to a metal via its four nitrogen donor atoms. Once porphine bonds to a metal ion, the two H atoms on the nitrogens are displaced to form complexes called **porphyrins**. Two important porphyrins are *hemes*, in which the metal ion is Fe(II), and *chlorophylls*, with a Mg(II) central ion.

▼ **FIGURE 23.14** shows a schematic structure of myoglobin, a protein that contains one heme group. Myoglobin is a *globular protein*, one that folds into a compact, roughly spherical shape. Myoglobin is found in the cells of skeletal muscle, particularly in seals, whales, and porpoises. It stores oxygen in cells, one molecule of O_2 per myoglobin, until it is needed for metabolic activities. Hemoglobin, the protein that transports oxygen in human blood, is made up of four heme-containing subunits, each of which is very similar to myoglobin. One hemoglobin can bind up to four O_2 molecules.

In both myoglobin and hemoglobin, the iron is coordinated to the four nitrogen atoms of a porphine and to a nitrogen atom from the protein chain (▶ **FIGURE 23.15**). In hemoglobin, the sixth position around the iron is occupied either by O_2 (in oxyhemoglobin, the

▲ **FIGURE 23.14** Myoglobin. This ribbon diagram does not show most of the atoms.

bright red form) or by water (in deoxyhemoglobin, the purplish red form). (The oxy form is the one shown in Figure 23.15.)

Carbon monoxide is poisonous because the equilibrium binding constant of human hemoglobin for CO is about 210 times greater than that for O₂. As a result, a relatively small quantity of CO can inactivate a substantial fraction of the hemoglobin in the blood. For example, a person breathing air that contains only 0.1% CO takes in enough CO after a few hours to convert up to 60% of the hemoglobin (Hb) into COHb, thereby reducing the blood's normal oxygen-carrying capacity by 60%.

Under normal conditions, a nonsmoker breathing unpolluted air has about 0.3 to 0.5% COHb in her or his blood. This amount arises mainly from the production of small quantities of CO in the course of normal body chemistry and from the small amount of CO present in clean air. Exposure to higher concentrations of CO causes the COHb level to increase, which in turn leaves fewer Hb sites to which O₂ can bind. If the level of COHb becomes too high, oxygen transport is effectively shut down and death occurs. Because CO is colorless and odorless, CO poisoning occurs with very little warning. Improperly ventilated combustion devices, such as kerosene lanterns and stoves, thus pose a potential health hazard.

GO FIGURE

Where would CO bind in this molecule?

▲ FIGURE 23.15 Coordination sphere of the hemes in oxyhemoglobin and oxyhemoglobin.

A CLOSER LOOK

ENTROPY AND THE CHELATE EFFECT

We learned in Section 19.5 that chemical processes are favored by positive entropy changes and by negative enthalpy changes. The special stability associated with the formation of chelates, called the *chelate effect*, can be explained by comparing the entropy changes that occur with monodentate ligands with the entropy changes that occur with polydentate ligands.

We begin with the reaction in which two H₂O ligands of the square-planar Cu(II) complex [Cu(H₂O)₄]²⁺ are replaced by monodentate NH₃ ligands at 27 °C:

The thermodynamic data tell us about the relative abilities of H₂O and NH₃ to serve as ligands in this reaction. In general, NH₃ binds more tightly to metal ions than does H₂O, so this substitution reaction is exothermic ($\Delta H < 0$). The stronger bonding of the NH₃ ligands also causes the [Cu(H₂O)₂(NH₃)₂]²⁺ ion to be more rigid, which is probably the reason ΔS° is slightly negative.

We can use Equation 19.20, $\Delta G^\circ = -RT \ln K$, to calculate the equilibrium constant of the reaction at 27 °C. The result, $K = 3.1 \times 10^7$, tells us that the equilibrium lies far to the right, favoring replacement of H₂O by NH₃. For this equilibrium, therefore, the enthalpy change, $\Delta H^\circ = -46 \text{ kJ}$, is large enough and negative enough to overcome the entropy change, $\Delta S^\circ = -8.4 \text{ J/K}$.

Now let's use a single bidentate ethylenediamine ligand in our substitution reaction:

The en ligand binds slightly more strongly to the Cu²⁺ ion than two NH₃ ligands, so the enthalpy change here (−54 kJ) is slightly more

negative than for [Cu(H₂O)₂(NH₃)₂]²⁺ (−46 kJ). There is a big difference in the entropy change, however: ΔS° is −8.4 J/K for the NH₃ reaction but +23 J/K for the en reaction. We can explain the positive ΔS° value by using concepts discussed in Section 19.3. Because a single en ligand occupies two coordination sites, two molecules of H₂O are released when one en ligand bonds. Thus, there are three product molecules in the reaction but only two reactant molecules. The greater number of product molecules leads to the positive entropy change for the equilibrium.

The slightly more negative value of ΔH° for the en reaction (−54 kJ versus −46 kJ) coupled with the positive entropy change leads to a much more negative value of ΔG° (−61 kJ for en, −43 kJ for NH₃) and a correspondingly larger equilibrium constant: $K = 4.2 \times 10^{10}$.

We can combine our two equations using Hess's law (Section 5.6) to calculate the enthalpy, entropy, and free-energy changes that occur for en to replace ammonia as ligands on Cu(II):

Notice that at 27 °C, the entropic contribution ($-T\Delta S^\circ$) to the free-energy change, $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$ (Equation 19.12), is negative and greater in magnitude than the enthalpic contribution (ΔH°). The equilibrium constant for the NH₃–en reaction, 1.4×10^3 , shows that the replacement of NH₃ by en is thermodynamically favorable.

The chelate effect is important in biochemistry and molecular biology. The additional thermodynamic stabilization provided by entropy effects helps stabilize biological metal–chelate complexes, such as porphyrins, and can allow changes in the oxidation state of the metal ion while retaining the structural integrity of the complex.

GO FIGURE

Which peak in this curve corresponds to the lowest-energy transition by an electron in a chlorophyll molecule?

▲ FIGURE 23.16 The absorption of sunlight by chlorophyll.

The **chlorophylls**, which are porphyrins that contain Mg(II) (Figure 23.13), are the key components in the conversion of solar energy into forms that can be used by living organisms. This process, called **photosynthesis**, occurs in the leaves of green plants:

The formation of 1 mol of glucose, $\text{C}_6\text{H}_{12}\text{O}_6$, requires the absorption of 48 mol of photons from sunlight or other sources of light. Chlorophyll-containing pigments in the leaves of plants absorb the photons. Figure 23.13 shows that the chlorophyll molecule has a series of alternating, or *conjugated*, double bonds in the ring surrounding the metal ion. This system of conjugated double bonds makes it possible for chlorophyll to absorb light strongly in the visible region of the spectrum. As ◀ FIGURE 23.16 shows, chlorophyll is green because it absorbs red light (maximum absorption at 655 nm) and blue light (maximum absorption at 430 nm) and transmits green light.

Photosynthesis is nature's solar-energy-conversion machine, and thus all living systems on Earth depend on photosynthesis for continued existence.

GIVE IT SOME THOUGHT

What property of the porphine ligand makes it possible for chlorophyll to play a role in plant photosynthesis?

CHEMISTRY AND LIFE

THE BATTLE FOR IRON IN LIVING SYSTEMS

Because living systems have difficulty assimilating enough iron to satisfy their nutritional needs, iron-deficiency anemia is a common problem in humans. Chlorosis, an iron deficiency in plants that makes leaves turn yellow, is also commonplace.

Living systems have difficulty assimilating iron because most iron compounds found in nature are not very soluble in water. Microorganisms have adapted to this problem by secreting an iron-binding compound, called a *siderophore*, that forms an extremely stable water-soluble complex with iron(III). One such complex is *ferrichrome* (▶ FIGURE 23.17). The iron-binding strength of a siderophore is so great that it can extract iron from glass cooking pots and the iron in iron oxides.

When ferrichrome enters a living cell, the iron it carries is removed through an enzyme-catalyzed reaction that reduces the strongly bonding iron(III) to iron(II), which is only weakly complexed by the siderophore (▶ FIGURE 23.18). Microorganisms thus acquire iron by excreting a siderophore into their immediate environment and then taking the resulting iron complex into the cell.

In humans, iron is assimilated from food in the intestine. A protein called *transferrin* binds iron and transports it across the intestinal wall to distribute it to other tissues in the body. The normal adult body contains about 4 g of iron. At any one time, about 3 g of this iron is in the blood, mostly in the form of hemoglobin. Most of the remainder is carried by transferrin.

A bacterium that infects the blood requires a source of iron if it is to grow and reproduce. The bacterium excretes a siderophore into the blood to compete with transferrin for iron. The equilibrium con-

▲ FIGURE 23.17 Ferrichrome.

stants for forming the iron complex are about the same for transferrin and siderophores. The more iron available to the bacterium, the more rapidly it can reproduce and thus the more harm it can do.

Several years ago, New Zealand clinics regularly gave iron supplements to infants soon after birth. However, the incidence of certain bacterial infections was eight times higher in treated than in

▲ FIGURE 23.18 The iron-transport system of a bacterial cell.

untreated infants. Presumably, the presence of more iron in the blood than absolutely necessary makes it easier for bacteria to obtain the iron needed for growth and reproduction.

In the United States it is common medical practice to supplement infant formula with iron sometime during the first year of life. However, iron supplements are not necessary for infants who breast-feed because breast milk contains two specialized proteins, lactoferrin and transferrin, which provide sufficient iron while denying its availability to bacteria. Even for infants fed with infant formulas, supplementing with iron during the first several months of life may be ill-advised.

For bacteria to continue to multiply in the blood, they must synthesize new supplies of siderophores. Synthesis of siderophores in bacteria slows, however, as the temperature is increased above the normal body temperature of 37°C and stops completely at 40°C . This suggests that fever in the presence of an invading microbe is a mechanism used by the body to deprive bacteria of iron.

23.4 NOMENCLATURE AND ISOMERISM IN COORDINATION CHEMISTRY

When complexes were first discovered, they were named after the chemist who originally prepared them. A few of these names persist, as, for example, with the dark red substance $\text{NH}_4[\text{Cr}(\text{NH}_3)_2(\text{NCS})_4]$, which is still known as Reinecke's salt. Once the structures of complexes were more fully understood, it became possible to name them in a more systematic manner. Let's use two substances to illustrate how coordination compounds are named:

- In naming complexes that are salts, the name of the cation is given before the name of the anion.** Thus, in $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2$ we name the $[\text{Co}(\text{NH}_3)_5\text{Cl}]^{2+}$ cation and then the Cl^- .
- In naming complex ions or molecules, the ligands are named before the metal.** Ligands are listed in alphabetical order, regardless of their charges. Prefixes that give the number of ligands are not considered part of the ligand name in determining alphabetical order. Thus, the $[\text{Co}(\text{NH}_3)_5\text{Cl}]^{2+}$ ion is pentaamminechlorocobalt(III). (Be careful to note, however, that the metal is written first in the chemical formula.)

TABLE 23.5 • Some Common Ligands and Their Names

Ligand	Name in Complexes	Ligand	Name in Complexes
Azide, N_3^-	Azido	Oxalate, $\text{C}_2\text{O}_4^{2-}$	Oxalato
Bromide, Br^-	Bromo	Oxide, O^{2-}	Oxo
Chloride, Cl^-	Chloro	Ammonia, NH_3	Ammine
Cyanide, CN^-	Cyano	Carbon monoxide, CO	Carbonyl
Fluoride, F^-	Fluoro	Ethylenediamine, en	Ethylenediamine
Hydroxide, OH^-	Hydroxo	Pyridine, $\text{C}_5\text{H}_5\text{N}$	Pyridine
Carbonate, CO_3^{2-}	Carbonato	Water, H_2O	Aqua

- The names of anionic ligands end in the letter *o*, but electrically neutral ligands ordinarily bear the name of the molecules (▲ TABLE 23.5). Special names are used for H_2O (aqua), NH_3 (ammine), and CO (carbonyl). For example, $[\text{Fe}(\text{CN})_2(\text{NH}_3)_2(\text{H}_2\text{O})_2]^+$ is the diamminediaquadicyanoiron(III) ion.
- Greek prefixes (*di-*, *tri-*, *tetra-*, *penta-*, *hexa-*) are used to indicate the number of each kind of ligand when more than one is present. If the ligand contains a Greek prefix (for example, *ethylenediamine*) or is polydentate, the alternate prefixes *bis-*, *tris-*, *tetrakis-*, *pentakis-*, and *hexakis-* are used and the ligand name is placed in parentheses. For example, the name for $[\text{Co}(\text{en})_3]\text{Br}_3$ is tris(ethylenediamine)-cobalt(III) bromide.
- If the complex is an anion, its name ends in *-ate*. The compound $\text{K}_4[\text{Fe}(\text{CN})_6]$ is potassium hexacyanoferrate(II), for example, and the ion $[\text{CoCl}_4]^{2-}$ is tetrachlorocobaltate(II) ion.
- The oxidation number of the metal is given in parentheses in Roman numerals following the name of the metal.

Three examples for applying these rules are

$[\text{Ni}(\text{NH}_3)_6]\text{Br}_2$	Hexaamminenickel(II) bromide
$[\text{Co}(\text{en})_2(\text{H}_2\text{O})(\text{CN})]\text{Cl}_2$	Aquacyanobis(ethylenediamine)cobalt(III) chloride
$\text{Na}_2[\text{MoOCl}_4]$	Sodium tetrachlorooxomolybdate(IV)

SAMPLE EXERCISE 23.4 Naming Coordination Compounds

Name the compounds (a) $[\text{Cr}(\text{H}_2\text{O})_4\text{Cl}_2]\text{Cl}$, (b) $\text{K}_4[\text{Ni}(\text{CN})_4]$.

SOLUTION

Analyze We are given the chemical formulas for two coordination compounds and assigned the task of naming them.

Plan To name the complexes, we need to determine the ligands in the complexes, the names of the ligands, and the oxidation state of the metal ion. We then put the information together following the rules listed in the text.

Solve

(a) The ligands are four water molecules—tetraaqua—and two chloride ions—dichloro. By assigning all the oxidation numbers we know for this molecule, we see that the oxidation number of Cr is +3:

Thus, we have chromium(III). Finally, the anion is chloride. The name of the compound is

(b) The complex has four cyanide ion ligands, CN^- , which means tetracyano, and the oxidation state of the nickel is zero:

Because the complex is an anion, the metal is indicated as nickelate(0). Putting these parts together and naming the cation first, we have

tetraaquadichlorochromium(III) chloride

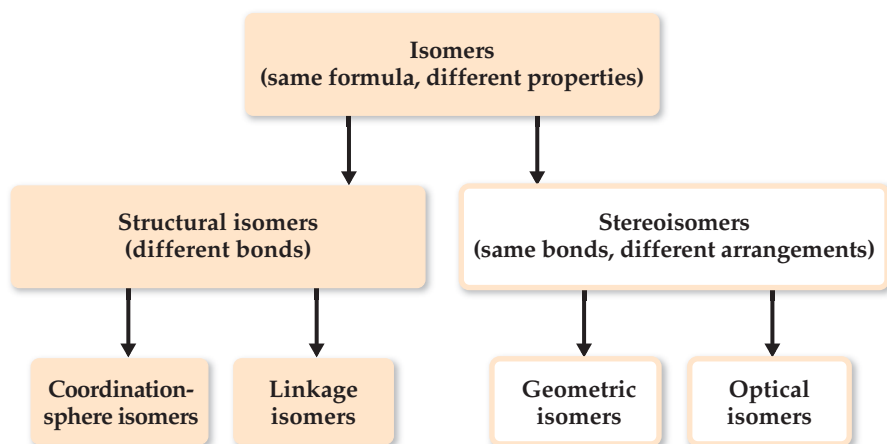

potassium tetracyanonickelate(0)

PRACTICE EXERCISE

Name the compounds (a) $[\text{Mo}(\text{NH}_3)_3\text{Br}_3]\text{NO}_3$, (b) $(\text{NH}_4)_2[\text{CuBr}_4]$. (c) Write the formula for sodium diaquabis(oxalato)ruthenate(III).

Answers: (a) triamminetribromomolybdenum(IV) nitrate, (b) ammonium tetrabromocuprate(II)
(c) $\text{Na}[\text{Ru}(\text{H}_2\text{O})_2(\text{C}_2\text{O}_4)_2]$

◀ **FIGURE 23.19** Forms of isomerism in coordination compounds.

Isomerism

When two or more compounds have the same composition but a different arrangement of atoms, we call them **isomers**. ∞ (Section 2.9) Here we consider two main kinds of isomers in coordination compounds: **structural isomers** (which have different bonds) and **stereoisomers** (which have the same bonds but different ways in which the ligands occupy the space around the metal center). Each of these classes also has subclasses, as shown in ▲ **FIGURE 23.19**.

Structural Isomerism

Many types of structural isomerism are known in coordination chemistry, including the two named in Figure 23.19: linkage isomerism and coordination-sphere isomerism.

Linkage isomerism is a relatively rare but interesting type that arises when a particular ligand is capable of coordinating to a metal in two ways. The nitrite ion, NO_2^- , for example, can coordinate to a metal ion through either its nitrogen or one of its oxygens (► **FIGURE 23.20**). When it coordinates through the nitrogen atom, the NO_2^- ligand is called *nitro*; when it coordinates through the oxygen atom, it is called *nitrito* and is generally written ONO^- . The isomers shown in Figure 23.20 have different properties. The nitro isomer is yellow, for example, whereas the nitrito isomer is red.

Another ligand capable of coordinating through either of two donor atoms is thiocyanate, SCN^- , whose potential donor atoms are N and S.

Coordination-sphere isomers are isomers that differ in which species in the complex are ligands and which are outside the coordination sphere in the solid lattice. For example, three isomers have the formula $\text{CrCl}_3(\text{H}_2\text{O})_6$. When the ligands are six H_2O and the chloride ions are in the crystal lattice (as counterions), we have the violet compound $[\text{Cr}(\text{H}_2\text{O})_6]\text{Cl}_3$. When the ligands are five H_2O and one Cl^- , with the sixth H_2O and the two Cl^- out in the lattice, we have the green compound $[\text{Cr}(\text{H}_2\text{O})_5\text{Cl}]\text{Cl}_2 \cdot \text{H}_2\text{O}$. The third isomer, $[\text{Cr}(\text{H}_2\text{O})_4\text{Cl}_2]\text{Cl} \cdot 2 \text{H}_2\text{O}$, is also a green compound. In the two green compounds, either one or two water molecules have been displaced from the coordination sphere by chloride ions and occupy a site in the crystal lattice.

► **FIGURE 23.21** Geometric isomerism.

cis
Cl ligands adjacent to each other
NH₃ ligands adjacent to each other

trans
Cl ligands on opposite sides of central atom
NH₃ ligands on opposite sides of central atom

Stereoisomerism

Stereoisomers have the same chemical bonds but different spatial arrangements. In the square-planar complex $[\text{Pt}(\text{NH}_3)_2\text{Cl}_2]$, for example, the chloro ligands can be either adjacent to or opposite each other (▲ **FIGURE 23.21**). (We saw an earlier example of this type of isomerism in the cobalt complex of Figure 23.7, and we'll return to that complex in a moment.) This form of stereoisomerism, in which the arrangement of the atoms is different but the same bonds are present, is called **geometric isomerism**. The isomer on the left in Figure 23.21, with like ligands in adjacent positions, is the *cis* isomer, and the isomer on the right, with like ligands across from one another, is the *trans* isomer.

Geometric isomers generally have different physical properties and may also have markedly different chemical reactivities. For example, *cis*- $[\text{Pt}(\text{NH}_3)_2\text{Cl}_2]$, also called *cisplatin*, is effective in the treatment of testicular, ovarian, and certain other cancers, whereas the *trans* isomer is ineffective. This is because cisplatin forms a chelate with two nitrogens of DNA, displacing the chloride ligands. The chloride ligands of the *trans* isomer are too far apart to form the N-Pt-N chelate with DNA nitrogens.

Geometric isomerism is also possible in octahedral complexes when two or more different ligands are present, as in the *cis* and *trans* tetraamminedichlorocobalt(III) ion in Figure 23.7. Because all the corners of a tetrahedron are adjacent to one another, *cis-trans* isomerism is not observed in tetrahedral complexes.

SAMPLE EXERCISE 23.5 Determining the Number of Geometric Isomers

The Lewis structure $:\text{C}\equiv\text{O}:$ indicates that the CO molecule has two lone pairs of electrons. When CO binds to a transition-metal atom, it nearly always does so by using the C lone pair. How many geometric isomers are there for tetracarbonyldichloroiron(II)?

SOLUTION

Analyze We are given the name of a complex containing only monodentate ligands, and we must determine the number of isomers the complex can form.

Plan We can count the number of ligands to determine the coordination number of the Fe and then use the coordination number to predict the geometry. We can then either make a series of drawings with ligands in different positions to determine the number of isomers or deduce the number of isomers by analogy to cases we have discussed.

Solve The name indicates that the complex has four carbonyl (CO) ligands and two chloro (Cl^-) ligands, so its formula is $\text{Fe}(\text{CO})_4\text{Cl}_2$. The complex therefore has a coordination number of 6, and we can assume an octahedral geometry. Like $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^+$ (Figure 23.7), it has four ligands of one type and two of another. Consequently, there are two isomers possible: one with the Cl^- ligands across the metal from each other, *trans*- $[\text{Fe}(\text{CO})_4\text{Cl}_2]$, and one with the Cl^- ligands adjacent to each other, *cis*- $[\text{Fe}(\text{CO})_4\text{Cl}_2]$.

Comment It is easy to overestimate the number of geometric isomers. Sometimes different orientations of a single isomer are incorrectly thought to be different isomers. If two structures can be rotated so that they are equivalent, they are not isomers of each other. The problem of identifying isomers is compounded by the difficulty we often have in visualizing three-dimensional molecules from their two-dimensional representations. It is sometimes easier to determine the number of isomers if we use three-dimensional models.

PRACTICE EXERCISE

How many isomers exist for the square-planar molecule $[\text{Pt}(\text{NH}_3)_2\text{ClBr}]$?

Answer: two

The second type of stereoisomerism listed in Figure 23.19 is **optical isomerism**. Optical isomers, called **enantiomers**, are mirror images that cannot be superimposed on each other. They bear the same resemblance to each other that your left hand bears to your right hand. If you look at your left hand in a mirror, the image is identical to your right hand (▼ FIGURE 23.22). No matter how hard you try, however, you cannot superimpose your two hands on each other. An example of a complex that exhibits this type of isomerism is the $[\text{Co}(\text{en})_3]^{3+}$ ion. Figure 23.22 shows the two enantiomers of this complex and their mirror-image relationship. Just as there is no way that we can twist or turn our right hand to make it look identical to our left, so also there is no way to rotate one of these enantiomers to make it identical to the other. Molecules or ions that are not superimposable on their mirror image are said to be **chiral** (pronounced KY-rul).

▲ FIGURE 23.22 Optical isomerism.

SAMPLE EXERCISE 23.6 Predicting Whether a Complex Has Optical Isomers

Does either $\text{cis-}[\text{Co}(\text{en})_2\text{Cl}_2]^+$ or $\text{trans-}[\text{Co}(\text{en})_2\text{Cl}_2]^+$ have optical isomers?

SOLUTION

Analyze We are given the chemical formula for two geometric isomers and asked to determine whether either one has optical isomers. Because en is a bidentate ligand, we know that both complexes are octahedral and both have coordination number 6.

Plan We need to sketch the structures of the cis and trans isomers and their mirror images. We can draw the en ligand as two N atoms connected by an arc. If the mirror image cannot be superimposed on the original structure, the complex and its mirror image are optical isomers.

Solve The trans isomer of $[\text{Co}(\text{en})_2\text{Cl}_2]^+$ and its mirror image are:

Notice that the mirror image of the isomer is identical to the original. Consequently *trans*- $[\text{Co}(\text{en})_2\text{Cl}_2]^+$ does not exhibit optical isomerism.

The mirror image of the cis isomer cannot be superimposed on the original:

Thus, the two cis structures are optical isomers (enantiomers). We say that *cis*- $[\text{Co}(\text{en})_2\text{Cl}_2]^+$ is a chiral complex.

PRACTICE EXERCISE

Does the square-planar complex ion $[\text{Pt}(\text{NH}_3)(\text{N}_3)\text{ClBr}]^-$ have optical isomers? Explain your answer.

Answer: no, because the complex is flat. This complex ion does, however, have geometric isomers (for example, the Cl and Br ligands could be cis or trans).

The properties of two optical isomers differ only if the isomers are in a chiral environment—that is, an environment in which there is a sense of right- and left-handedness. A chiral enzyme, for example, might catalyze the reaction of one optical isomer but not the other. Consequently, one optical isomer may produce a specific physiological effect in the body, with its mirror image producing either a different effect or none at all. Chiral reactions are also extremely important in the synthesis of pharmaceuticals and other industrially important chemicals.

Optical isomers are usually distinguished from each other by their interaction with plane-polarized light. If light is polarized—for example, by being passed through a sheet of polarizing film—the electric-field vector of the light is confined to a single plane (▼ FIGURE 23.23). If the polarized light is then passed through a solution containing one optical isomer, the plane of polarization is rotated either to the right or to the left. The isomer that rotates the plane of polarization to the right is **dextrorotatory**; it is the

► FIGURE 23.23 Using polarized light to detect optical activity.

dextro, or *d*, isomer (Latin *dexter*, “right”). Its mirror image rotates the plane of polarization to the left; it is **levorotatory** and is the levo, or *l*, isomer (Latin *laevus*, “left”). The $[\text{Co}(\text{en})_3]^{3+}$ isomer on the right in Figure 23.22 is found experimentally to be the *l* isomer of this ion. Its mirror image is the *d* isomer. Because of their effect on plane-polarized light, chiral molecules are said to be **optically active**.

GIVE IT SOME THOUGHT

What is the similarity and what is the difference between the *d* and *l* isomers of a compound?

When a substance with optical isomers is prepared in the laboratory, the chemical environment during the synthesis is not usually chiral. Consequently, equal amounts of the two isomers are obtained, and the mixture is said to be **racemic**. A racemic mixture does not rotate polarized light because the rotatory effects of the two isomers cancel each other.

23.5 COLOR AND MAGNETISM IN COORDINATION CHEMISTRY

Studies of the colors and magnetic properties of transition-metal complexes have played an important role in the development of modern models for metal–ligand bonding. We discussed the various types of magnetic behavior of the transition metals in Section 23.1, and we discussed the interaction of radiant energy with matter in Section 6.3. Let’s briefly examine the significance of these two properties for transition-metal complexes before we develop a model for metal–ligand bonding.

Color

In Figure 23.3 we saw the diverse range of colors seen in salts of transition-metal ions and their aqueous solutions. In general, the color of a complex depends on the identity of the metal ion, on its oxidation state, and on the ligands bound to it.  **FIGURE 23.24**, for instance, shows how the pale blue color characteristic of $[\text{Cu}(\text{H}_2\text{O})_4]^{2+}$ changes to deep blue as NH_3 ligands replace the H_2O ligands to form $[\text{Cu}(\text{NH}_3)_4]^{2+}$.

GO FIGURE

Is the equilibrium binding constant of ammonia for Cu(II) likely to be larger or smaller than that of water for Cu(II)?

 **FIGURE 23.24** The color of a coordination complex changes when the ligand changes.

▲ **FIGURE 23.25** Two ways of perceiving the color orange. An object appears orange either when it reflects orange light to the eye (left), or when it transmits to the eye all colors except blue, the complement of orange (middle). Complementary colors lie opposite to each other on an artist's color wheel (right).

For a substance to have color we can see, it must absorb some portion of the spectrum of visible light. ∞ (Section 6.1) Absorption happens, however, only if the energy needed to move an electron in the substance from its ground state to an excited state corresponds to the energy of some portion of the visible spectrum. ∞ (Section 6.3) Thus, the particular energies of radiation a substance absorbs dictate the color we see for the substance.

When an object absorbs some portion of the visible spectrum, the color we perceive is the sum of the unabsorbed portions, which are either reflected or transmitted by the object and strike our eyes. (Opaque objects *reflect* light, and transparent ones *transmit* it.) If an object absorbs all wavelengths of visible light, none reaches our eyes and the object appears black. If it absorbs no visible light, it is white if it is a solid or colorless if it is a liquid. If it absorbs all but orange light, the orange light is what reaches our eye and therefore the color we see.

An interesting phenomenon of vision is that we also perceive an orange color when an object absorbs only the blue portion of the visible spectrum and all the other colors strike our eyes. This is because orange and blue are **complementary colors**, which means that the removal of blue from white light makes the light look orange (and the removal of orange makes the light look blue).

Complementary colors can be determined with an artist's color wheel, which shows complementary colors on opposite sides (▲ **FIGURE 23.25**).

SAMPLE EXERCISE 23.7 Relating Color Absorbed to Color Observed

The complex ion $\text{trans-}[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^+$ absorbs light primarily in the red region of the visible spectrum (the most intense absorption is at 680 nm). What is the color of the complex?

SOLUTION

Analyze We need to relate the color absorbed by a complex (red) to the color observed for the complex.

Plan For an object that absorbs only one color from the visible spectrum, the color we see is complementary to the color absorbed. We can use the color wheel of Figure 23.25 to determine the complementary color.

Solve From Figure 23.25, we see that green is complementary to red, so the complex appears green.

Comment As noted in Section 23.2, this green complex was one of those that helped Werner establish his theory of coordination (Table 23.3). The other geometric isomer of this complex, $\text{cis-}[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^+$, absorbs yellow light and therefore appears violet.

PRACTICE EXERCISE

A certain transition-metal complex ion absorbs at 630 nm. Which color is this ion most likely to be—blue, yellow, green, or orange?

Answer: blue

The amount of light absorbed by a sample as a function of wavelength is known as the sample's **absorption spectrum**. The visible absorption spectrum of a transparent sample can be determined using a spectrometer, as described in the “A Closer Look” box on page 564. The absorption spectrum of the ion $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$ is shown in ► **FIGURE 23.26**. The absorption maximum is at 500 nm, but the graph shows that much of the yellow, green, and blue light is also absorbed. Because the sample absorbs all of these colors, what we see is the unabsorbed red and violet light, which we perceive as red-violet.

Magnetism of Coordination Compounds

Many transition-metal complexes exhibit paramagnetism, as described in Sections 9.8 and 23.1. In such compounds the metal ions possess some number of unpaired electrons. It is possible to experimentally determine the number of unpaired electrons per metal ion from the measured degree of paramagnetism, and experiments reveal some interesting comparisons.

Compounds of the complex ion $[\text{Co}(\text{CN})_6]^{3-}$ have no unpaired electrons, for example, but compounds of the $[\text{CoF}_6]^{3-}$ ion have four unpaired electrons per metal ion. Both complexes contain Co(III) with a $3d^6$ electron configuration. ∞ (Section 7.4) Clearly, there is a major difference in the ways in which the electrons are arranged in these two cases. Any successful bonding theory must explain this difference, and we present such a theory in the next section.

GIVE IT SOME THOUGHT

What is the electron configuration for

- the Co atom and
- the Co^{3+} ion? How many unpaired electrons does each possess? (See Section 7.4 to review electron configurations of ions.)

23.6 CRYSTAL-FIELD THEORY

Scientists have long recognized that many of the magnetic properties and colors of transition-metal complexes are related to the presence of d electrons in the metal cation. In this section we consider a model for bonding in transition-metal complexes, **crystal-field theory**, that accounts for many of the observed properties of these substances.* Because the predictions of crystal-field theory are essentially the same as those obtained with more advanced molecular-orbital theories, crystal-field theory is an excellent place to start in considering the electronic structure of coordination compounds.

The ability of a metal ion to attract ligands is a Lewis acid–base interaction, in which the base—that is, the ligand—donates a pair of electrons to an empty orbital on the metal ion (► **FIGURE 23.27**). Much of the attractive interaction between the metal ion and the ligands is due, however, to the electrostatic forces between the positive charge on the metal ion and negative charges on the ligands. If the ligand is ionic, as in the case of Cl^- or SCN^- , the electrostatic interaction is the usual cation–anion attraction. When the ligand is a neutral molecule, as in the case of H_2O or NH_3 , the negative ends of these polar molecules, which contain an unshared electron pair, are directed toward the metal ion. In this case, the attractive interaction is of the ion–dipole type. ∞ (Section 11.2) In either case, the ligands are attracted strongly toward the metal ion. Because of the metal–ligand electrostatic attraction, the energy of the complex is lower than the combined energy of the separated metal ion and ligands.

Although the metal ion is attracted to the ligand electrons, the metal ion's d electrons are repulsed by the ligands. Let's examine this effect more closely, specifically the case in which the ligands form an octahedral array around a metal ion that has coordination number 6.

GO FIGURE
How would this absorbance spectrum change if you decreased the concentration of the $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$ in solution?

▲ **FIGURE 23.26** The color of $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$. A solution containing the $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$ ion appears red-violet because, as its visible absorption spectrum shows, the solution does not absorb light from the violet and red ends of the spectrum. That unabsorbed light is what reaches our eyes.

▲ **FIGURE 23.27** Metal–ligand bond formation. The ligand acts as a Lewis base by donating its nonbonding electron pair to a hybrid orbital on the metal ion. The bond that results is strongly polar with some covalent character.

*The name *crystal field* arose because the theory was first developed to explain the properties of solid crystalline materials. The theory applies equally well to complexes in solution, however.

GO FIGURE

Which d orbitals have lobes that point directly toward the ligands in an octahedral crystal field?

▲ FIGURE 23.28 Energies of d orbitals in a free metal ion, a spherically symmetric crystal field, and an octahedral crystal field.

In crystal-field theory, we consider the ligands to be negative points of charge that repel the electrons in the d orbitals of the metal ion. The energy diagram in ▲ FIGURE 23.28 shows how these ligand point charges affect the energies of the d orbitals. First we imagine the complex as having all the ligand point charges uniformly distributed on the surface of a sphere centered on the metal ion. The *average* energy of the metal ion's d orbitals is raised by the presence of this uniformly charged sphere. Hence, the energies of all five d orbitals are raised by the same amount.

This energy picture is only a first approximation, however, because the ligands are not distributed uniformly on a spherical surface and, therefore, do not approach the metal ion equally from every direction. Instead, we envision the six ligands approaching along x -, y -, and z -axes, as shown on the right in Figure 23.28. This arrangement of ligands is called an *octahedral crystal field*. Because the metal ion's d orbitals have different orientations and shapes, they do not all experience the same repulsion from the ligands and, therefore, do not all have the same energy under the influence of the octahedral crystal field. To see why, we must consider the shapes of the d orbitals and how their lobes are oriented relative to the ligands.

Figure 23.28 shows that the lobes of the d_{z^2} and $d_{x^2-y^2}$ orbitals are directed *along* the x -, y -, and z -axes and so point directly toward the ligand point charges. In the d_{xy} , d_{xz} , and d_{yz} orbitals, however, the lobes are directed *between* the axes and so do not point directly toward the charges. The result of this difference in orientation— $d_{x^2-y^2}$ and d_{z^2} lobes point directly toward the ligand charges; d_{xy} , d_{xz} , and d_{yz} lobes do not—is that the energy of the $d_{x^2-y^2}$ and d_{z^2} orbitals is higher than the energy of the d_{xy} , d_{xz} , and d_{yz} orbitals. This difference in energy is represented by the red boxes in the energy diagram of Figure 23.28.

It might seem like the energy of the $d_{x^2-y^2}$ orbital should be different from that of the d_{z^2} orbital because the $d_{x^2-y^2}$ has four lobes pointing at ligands and the d_{z^2} has only two lobes pointing at ligands. However, the d_{z^2} orbital does have electron density in the xy plane, represented by the ring encircling the point where the two lobes meet. More advanced calculations show that two orbitals do indeed have the same energy in the presence of the octahedral crystal field.

Because their lobes point directly at the negative ligand charges, electrons in the metal ion's d_{z^2} and $d_{x^2-y^2}$ orbitals experience stronger repulsions than those in the d_{xy} , d_{xz} , and d_{yz} orbitals. As a result, the energy splitting shown in Figure 23.28 occurs. The three lower-energy d orbitals are called the t_2 set of orbitals, and the two higher-energy ones are called the e set.* The energy gap Δ between the two sets is often called the *crystal-field splitting energy*.

*The labels t_2 for the d_{xy} , d_{xz} , and d_{yz} orbitals and e for the d_{z^2} and $d_{x^2-y^2}$ orbitals come from the application of a branch of mathematics called *group theory* to crystal-field theory. Group theory can be used to analyze the effects of symmetry on molecular properties.

Crystal-field theory helps us account for the colors observed in transition-metal complexes. The energy gap Δ between the e and t_2 sets of d orbitals is of the same order of magnitude as the energy of a photon of visible light. It is therefore possible for a transition-metal complex to absorb visible light that excites an electron from a lower-energy (t_2) d orbital into a higher-energy (e) one. In $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$, for example, the Ti(III) ion has an $[\text{Ar}]3d^1$ electron configuration. (Recall from Section 7.4 that when determining the electron configurations of transition-metal ions, we remove the s electrons first.) Ti(III) is thus called a d^1 ion. In the ground state of $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$, the single $3d$ electron resides in an orbital in the t_2 set (► FIGURE 23.29). Absorption of 495-nm light excites this electron up to an orbital in the e set, generating the absorption spectrum shown in Figure 23.26. Because this transition involves exciting an electron from one set of d orbitals to the other, we call it a **d - d transition**. As noted earlier, the absorption of visible radiation that produces this d - d transition causes the $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$ ion to appear red-violet.

GIVE IT SOME THOUGHT

Why are compounds of Ti(IV) colorless?

The magnitude of the crystal-field splitting energy and, consequently, the color of a complex depend on both the metal and the ligands. For example, $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$ is light violet, $[\text{Cr}(\text{H}_2\text{O})_6]^{3+}$ is a deeper violet, and $[\text{Cr}(\text{NH}_3)_6]^{3+}$ is yellow. In a ranking called the **spectrochemical series**, ligands are arranged in order of their abilities to increase splitting energy, as in this abbreviated list:

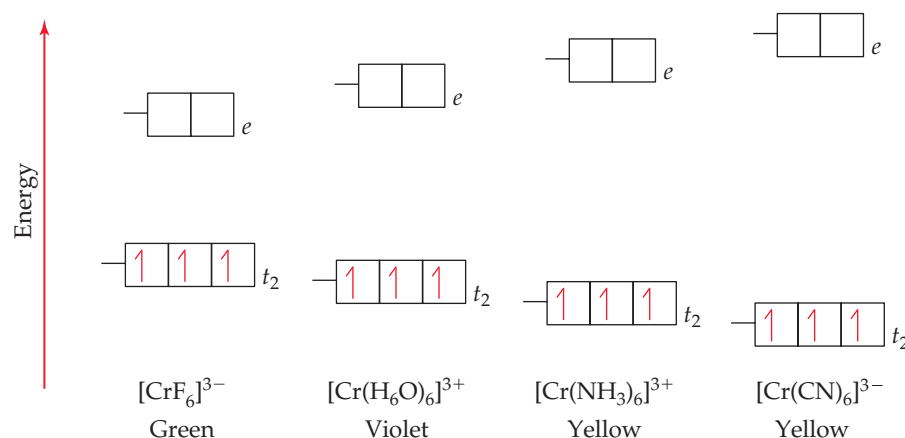

The magnitude of Δ increases by roughly a factor of 2 from the far left to the far right of the spectrochemical series. Ligands at the low- Δ end of the spectrochemical series are termed *weak-field ligands*; those at the high- Δ end are termed *strong-field ligands*.

▼ FIGURE 23.30 shows what happens to crystal-field splitting when the ligand is varied in a series of chromium(III) complexes. Because the Cr atom has an $[\text{Ar}]3d^54s^1$ electron configuration, Cr^{3+} has the configuration $[\text{Ar}]3d^3$ and therefore is a d^3 ion. Consistent with Hund's rule, the three $3d$ electrons occupy the t_2 set of orbitals, with one electron in each orbital and all the spins the same. ∞ (Section 6.8) As the crystal field exerted by the six ligands increases, Δ increases. Because the absorption spectrum is related to this energy separation, these complexes vary in color.

GO FIGURE

If you were told to add a colorless Cr(III) complex to this diagram, what would you draw and where would you place it?

▲ FIGURE 23.30 Effect of ligand on crystal-field splitting. The greater the crystal-field strength of the ligand, the greater the energy gap Δ it causes between the t_2 and e sets of the metal ion's d orbitals.

GO FIGURE

How would you calculate the energy gap between the t_2 and e orbitals from this diagram?

▲ FIGURE 23.29 The d - d transition in $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$ is produced by the absorption of 495-nm light.

SAMPLE EXERCISE 23.8 Using the Spectrochemical Series

$[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$, $[\text{Ti}(\text{en})_3]^{3+}$, and $[\text{TiCl}_6]^{3-}$ all absorb visible light. Which one absorbs at the shortest wavelength?

SOLUTION

Analyze We are given three octahedral complexes, each containing Ti in the +3 oxidation state. We need to predict which complex absorbs the shortest wavelength of visible light.

Plan Ti(III) is a d^1 ion, so we anticipate that the absorption is due to a $d-d$ transition in which the $3d$ electron is excited from a t_2 orbital to an e orbital. The wavelength of the light absorbed is determined by the magnitude of the crystal-field splitting energy, Δ . Thus, we use the position of the ligands in the spectrochemical series to predict the relative values of Δ . The larger the splitting energy, the shorter the wavelength.

Solve Of these three ligands, ethylenediamine (en) is highest in the spectrochemical series and therefore causes the largest split between the t_2 and e orbitals. The larger the split, the shorter the wavelength of the light absorbed. Thus, the complex that absorbs the shortest-wavelength light is $[\text{Ti}(\text{en})_3]^{3+}$.

PRACTICE EXERCISE

The absorption spectrum of a Ti(III) complex containing the ligand L, $[\text{TiL}_6]^{3-}$, shows a peak maximum at a wavelength intermediate between the wavelengths of the absorption maxima for $[\text{TiCl}_6]^{3-}$ and $[\text{TiF}_6]^{3-}$. What can we conclude about the place of L in the spectrochemical series?

Answer: It lies between Cl^- and F^- .

Electron Configurations in Octahedral Complexes

▲ FIGURE 23.31 Two possibilities for adding a fourth electron to a d^3 octahedral complex. Whether the fourth electron goes into a t_2 orbital or into an e orbital depends on the relative energies of the crystal-field splitting energy and the spin-pairing energy.

Crystal-field theory helps us understand the magnetic properties and some important chemical properties of transition-metal ions. From Hund's rule, we expect electrons to always occupy the lowest-energy vacant orbitals first and to occupy a set of degenerate (same-energy) orbitals one at a time with their spins parallel. ∞ (Section 6.8) Thus, if we have a d^1 , d^2 , or d^3 octahedral complex, the electrons go into the lower-energy t_2 orbitals, with their spins parallel. When a fourth electron must be added, we have the two choices shown in **FIGURE 23.31**: The electron can either go into an e orbital, where it will be the sole electron in the orbital, or become the second electron in a t_2 orbital. Because the energy difference between the t_2 and e sets is the splitting energy Δ , the energy cost of going into an e orbital rather than a t_2 orbital is also Δ . Thus, the goal of filling lowest-energy available orbitals first is met by putting the electron in a t_2 orbital.

There is a penalty for doing this, however, because the electron must now be paired with the electron already occupying the orbital. The difference between the energy required to pair an electron in an occupied orbital and the energy required to place that electron in an empty orbital is called the **spin-pairing energy**. The spin-pairing energy arises from the fact that the electrostatic repulsion between two electrons that share an orbital (and so must have opposite spins) is greater than the repulsion between two electrons that are in different orbitals and have parallel spins.

In coordination complexes, the nature of the ligands and the charge on the metal ion often play major roles in determining which of the two electron arrangements shown in Figure 23.31 is used. In $[\text{CoF}_6]^{3-}$ and $[\text{Co}(\text{CN})_6]^{3-}$, both ligands have a 1- charge. The F^- ion, however, is on the low end of the spectrochemical series, so it is a weak-field ligand. The CN^- ion is on the high end and so is a strong-field ligand, which means it produces a larger energy gap Δ than the F^- ion. The splittings of the d -orbital energies in these two complexes are compared in **FIGURE 23.32**.

Cobalt(III) has an $[\text{Ar}]3d^6$ electron configuration, so both complexes in Figure 23.32 are d^6 complexes. Let's imagine that we add these six electrons one at a time to the d orbitals of the $[\text{CoF}_6]^{3-}$ ion. The first three go into the t_2 orbitals with their spins parallel. The fourth electron could pair up in one of the t_2 orbitals. The F^- ion is a weak-field ligand, however, and so the energy gap Δ between the t_2 set and the e set is small. In this case, the more stable arrangement is the fourth electron in one of the e orbitals. By the

same energy argument, the fifth electron goes into the other e orbital. With all five d orbitals containing one electron, the sixth must pair up, and the energy needed to pair with a t_2 electron is less than that needed to pair with an e electron. We end up with four t_2 electrons and two e electrons.

Figure 23.32 shows that the crystal-field splitting energy Δ is much larger in the $[\text{Co}(\text{CN})_6]^{3-}$ complex. In this case, the spin-pairing energy is smaller than Δ , so the lowest-energy arrangement is the six electrons paired in the t_2 orbitals.

The $[\text{CoF}_6]^{3-}$ complex is a **high-spin complex**; that is, the electrons are arranged so that they remain unpaired as much as possible. The $[\text{Co}(\text{CN})_6]^{3-}$ ion is a **low-spin complex**; that is, the electrons are arranged so that they remain paired as much as possible while still following Hund's rule. These two electronic arrangements can be readily distinguished by measuring the magnetic properties of the complex. Experiments show that $[\text{CoF}_6]^{3-}$ has four unpaired electrons and $[\text{Co}(\text{CN})_6]^{3-}$ has none. The absorption spectrum also shows peaks corresponding to the different values of Δ in these two complexes.

GIVE IT SOME THOUGHT

Are strong-field ligands more likely to lead to a high-spin complex or a low-spin complex?

In the transition metal ions of periods 5 and 6 (which have $4d$ and $5d$ valence electrons), the d orbitals are larger than in the period 4 ions (which have only $3d$ electrons). Thus, ions from periods 5 and 6 interact more strongly with ligands, resulting in a larger crystal-field splitting. Consequently, metal ions in periods 5 and 6 are invariably low spin in an octahedral crystal field.

SAMPLE EXERCISE 23.9 Predicting the Number of Unpaired Electrons in an Octahedral Complex

Predict the number of unpaired electrons in high-spin and low-spin Fe^{3+} complexes that have a coordination number of 6.

SOLUTION

Analyze We must determine how many unpaired electrons there are in the high-spin and low-spin complexes of Fe^{3+} .

Plan We need to consider how the electrons populate the d orbitals in Fe^{3+} when the metal is in an octahedral complex. There are two possibilities: one giving a high-spin complex and the other giving a low-spin complex. The electron configuration of Fe^{3+} gives us the number of d electrons. We then determine how these electrons populate the t_2 and e sets of d orbitals. In the high-spin case, the energy difference between the t_2 and e orbitals is small, and the complex has the maximum number of unpaired electrons. In the low-spin case, the energy difference between the t_2 and e orbitals is large, causing the t_2 orbitals to be filled before any electrons occupy the e orbitals.

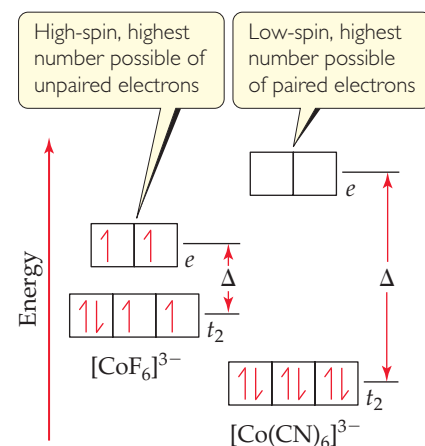

Solve Fe^{3+} is a d^5 ion. In a high-spin complex, all five electrons are unpaired, with three in the t_2 orbitals and two in the e orbitals. In a low-spin complex, all five electrons reside in the t_2 set, so there is one unpaired electron:

PRACTICE EXERCISE

In octahedral complexes, for which d electron configurations is it possible to distinguish between high-spin and low-spin arrangements?

Answer: d^4 , d^5 , d^6 , d^7

▲ FIGURE 23.32 High-spin and low-spin complexes. The high-spin $[\text{CoF}_6]^{3-}$ ion has a weak-field ligand and so a small Δ value. The spin-pairing energy required to pair electrons in the t_2 orbitals is greater than the e - t_2 gap energy Δ . Therefore, filling e orbitals before any electrons are paired in t_2 orbitals is the lower-energy state. The low-spin $[\text{Co}(\text{CN})_6]^{3-}$ ion has a strong-field ligand and so a large Δ value. Here the spin-pairing energy is less than Δ , making three sets of t_2 -paired electrons the lower-energy state.

Tetrahedral and Square-Planar Complexes

Thus far we have considered crystal-field theory only for complexes having an octahedral geometry. When there are only four ligands in a complex, the geometry is generally tetrahedral, except for the special case of d^8 metal ions, which we will discuss in a moment.

▲ **FIGURE 23.33** Energies of the d orbitals in a tetrahedral crystal field. The t_2 set is the higher-energy set. Compare the relative e and t_2 energy levels here with those in Figure 23.28 for an octahedral crystal field.

GO FIGURE
Why is the $d_{x^2-y^2}$ orbital the highest-energy orbital in the square-planar crystal field?

▲ **FIGURE 23.34** Energies of the d orbitals in a square-planar crystal field.

The crystal-field splitting of d orbitals in tetrahedral complexes differs from that in octahedral complexes. Four equivalent ligands can interact with a central metal ion most effectively by approaching along the vertices of a tetrahedron. It turns out—and this is not easy to explain in just a few sentences—that when d orbitals split in a tetrahedral crystal, the three t_2 orbitals are raised in energy above the two e orbitals (◀ **FIGURE 23.33**). Because there are only four ligands instead of six, as in the octahedral case, the crystal-field splitting energy Δ is much smaller for tetrahedral complexes. Calculations show that for the same metal ion and ligand set, Δ for the tetrahedral complex is only four-ninths as large as for the octahedral complex. For this reason, all tetrahedral complexes are high spin; the crystal-field splitting energy is never large enough to overcome the spin-pairing energies.

In a square-planar complex, four ligands are arranged about the metal ion such that all five species are in the xy plane. The resulting energy levels of the d orbitals are illustrated in ◀ **FIGURE 23.34**. Note in particular that the d_{z^2} orbital is considerably lower in energy than the $d_{x^2-y^2}$ orbital. To understand why this is so, recall from Figure 23.28 that in an octahedral field the d_{z^2} orbital of the metal ion interacts with the ligands positioned above and below the xy plane. There are no ligands in these two positions in a square-planar complex, which means that the d_{z^2} orbital experiences no repulsive force and so remains in a lower-energy, more stable state.

Square-planar complexes are characteristic of metal ions with a d^8 electron configuration. They are nearly always low spin, with the eight d electrons spin-paired to form a diamagnetic complex. This pairing leaves the $d_{x^2-y^2}$ orbital empty. Such an electronic arrangement is particularly common among the ions of heavier metals, such as Pd^{2+} , Pt^{2+} , Ir^+ , and Au^{3+} .

GIVE IT SOME THOUGHT

Why is the energy of the d_{xz} and d_{yz} orbitals in a square-planar complex lower than that of the d_{xy} orbital?

SAMPLE EXERCISE 23.10 Populating d Orbitals in Tetrahedral and Square-Planar Complexes

Nickel(II) complexes in which the metal coordination number is 4 can have either square-planar or tetrahedral geometry. $[\text{NiCl}_4]^{2-}$ is paramagnetic, and $[\text{Ni}(\text{CN})_4]^{2-}$ is diamagnetic. One of these complexes is square planar, and the other is tetrahedral. Use the relevant crystal-field splitting diagrams in the text to determine which complex has which geometry.

SOLUTION

Analyze We are given two complexes containing Ni^{2+} and their magnetic properties. We are given two molecular geometry choices and asked to use crystal-field splitting diagrams from the text to determine which complex has which geometry.

Plan We need to determine the number of d electrons in Ni^{2+} and then use Figure 23.33 for the tetrahedral complex and Figure 23.34 for the square-planar complex.

Solve Nickel(II) has the electron configuration $[\text{Ar}]3d^8$. Tetrahedral complexes are always high spin, and square-planar complexes are almost always low spin. Therefore, the population of the d electrons in the two geometries is

The tetrahedral complex has two unpaired electrons, and the square-planar complex has none. We know from Section 23.1 that the tetrahedral complex must be paramagnetic and

the square planar must be diamagnetic. Therefore, $[\text{NiCl}_4]^{2-}$ is tetrahedral, and $[\text{Ni}(\text{CN})_4]^{2-}$ is square planar.

Comment Nickel(II) forms octahedral complexes more frequently than square-planar ones, whereas heavier d^8 metals tend to favor square-planar coordination.

PRACTICE EXERCISE

How many unpaired electrons do you predict for the tetrahedral $[\text{CoCl}_4]^{2-}$ ion?

Answer: three

Crystal-field theory can be used to explain many observations in addition to those we have discussed. The theory is based on electrostatic interactions between ions and atoms, which essentially means ionic bonds. Many lines of evidence show, however, that

A CLOSER LOOK

CHARGE-TRANSFER COLOR

In the laboratory portion of your course, you have probably seen many colorful transition-metal compounds, including those shown in **FIGURE 23.35**. Many of these compounds are colored because of $d-d$ transitions. Some colored complexes, however, including the violet permanganate ion, MnO_4^- , and the yellow chromate ion, CrO_4^{2-} , derive their color from a different type of excitation involving the d orbitals.

The permanganate ion strongly absorbs visible light, with a maximum absorption at 565 nm. Because violet is complementary to yellow, this strong absorption in the yellow portion of the visible spectrum is responsible for the violet color of salts and solutions of the ion. What is happening during this absorption of light? The MnO_4^- ion is a complex of Mn(VII). Because Mn(VII) has a d^0 electron configuration, the absorption cannot be due to a $d-d$ transition because there are no d electrons to excite! That does not mean, however, that the d orbitals are not involved in the transition. The excitation in the MnO_4^- ion is due to a *charge-transfer transition*, in which an electron on one oxygen ligand is excited into a vacant d orbital on the Mn ion (**FIGURE 23.36**). In essence, an electron is transferred from a ligand to the metal, so this transition is called a *ligand-to-metal charge-transfer (LMCT) transition*.

An LMCT transition is also responsible for the color of the CrO_4^{2-} , which is a d^0 Cr(VI) complex.

Also shown in Figure 23.35 is a salt of the perchlorate ion (ClO_4^-). Like MnO_4^- , ClO_4^- is tetrahedral and has its central atom

in the +7 oxidation state. However, because the Cl atom does not have low-lying d orbitals, exciting a Cl electron requires a more energetic photon than does MnO_4^- . The first absorption for ClO_4^- is in the ultraviolet portion of the spectrum, so all the visible light is transmitted and the salt appears white.

Other complexes exhibit charge-transfer excitations in which an electron from the metal atom is excited to an empty orbital on a ligand. Such an excitation is called a *metal-to-ligand charge-transfer (MLCT) transition*.

Charge-transfer transitions are generally more intense than $d-d$ transitions. Many metal-containing pigments used for oil painting, such as cadmium yellow (CdS), chrome yellow (PbCrO_4), and red ochre (Fe_2O_3), have intense colors because of charge-transfer transitions.

RELATED EXERCISES: 23.82, 23.83

FIGURE 23.36 Ligand-to-metal charge-transfer transition in MnO_4^- . As shown by the blue arrow, an electron is excited from a nonbonding pair on O into one of the empty d orbitals on Mn.

KMnO_4

K_2CrO_4

KClO_4

FIGURE 23.35 The colors of compounds can arise from charge-transfer transitions. KMnO_4 and K_2CrO_4 are colored due to ligand-to-metal charge-transfer transitions in their anions. KClO_4 's anion has no occupied d orbitals and its charge-transfer transition is at higher energy, corresponding to ultraviolet absorption; therefore it appears white.

the bonding in complexes must have some covalent character. Therefore, molecular-orbital theory (Sections 9.7 and 9.8) can also be used to describe the bonding in complexes, although the application of molecular-orbital theory to coordination compounds is beyond the scope of our discussion. Crystal-field theory, although not entirely accurate in all details, provides an adequate and useful first description of the electronic structure of complexes.

SAMPLE INTEGRATIVE EXERCISE Putting Concepts Together

The oxalate ion has the Lewis structure shown in Table 23.4. (a) Show the geometry of the complex formed when this ion complexes with cobalt(II) to form $[\text{Co}(\text{C}_2\text{O}_4)(\text{H}_2\text{O})_4]$. (b) Write the formula for the salt formed when three oxalate ions complex with $\text{Co}(\text{II})$, assuming that the charge-balancing cation is Na^+ . (c) Sketch all the possible geometric isomers for the cobalt complex formed in part (b). Are any of these isomers chiral? Explain. (d) The equilibrium constant for the formation of the cobalt(II) complex produced by coordination of three oxalate anions, as in part (b), is 5.0×10^9 , and the equilibrium constant for formation of the cobalt(II) complex with three molecules of *ortho*-phenanthroline (Table 23.4) is 9×10^{19} . From these results, what conclusions can you draw regarding the relative Lewis base properties of the two ligands toward cobalt(II)? (e) Using the approach described in Sample Exercise 17.14, calculate the concentration of free aqueous $\text{Co}(\text{II})$ ion in a solution initially containing 0.040 M oxalate (aq) and 0.0010 M $\text{Co}^{2+}(\text{aq})$.

SOLUTION

(a) The complex formed by coordination of one oxalate ion is octahedral:

(b) Because the oxalate ion has a charge of $2-$, the net charge of a complex with three oxalate anions and one Co^{2+} ion is $4-$. Therefore, the coordination compound has the formula $\text{Na}_4[\text{Co}(\text{C}_2\text{O}_4)_3]$.

(c) There is only one geometric isomer. The complex is chiral, however, in the same way that the $[\text{Co}(\text{en})_3]^{3+}$ complex is chiral (Figure 23.22). The two mirror images are not superimposable, so there are two enantiomers:

(d) The *ortho*-phenanthroline ligand is bidentate, like the oxalate ligand, so they both exhibit the chelate effect. Thus, we conclude that *ortho*-phenanthroline is a stronger Lewis base toward Co^{2+} than oxalate. This conclusion is consistent with what we learned about bases in Section 16.7, that nitrogen bases are generally stronger than oxygen bases. (Recall, for example, that NH_3 is a stronger base than H_2O .)

(e) The equilibrium we must consider involves 3 mol of oxalate ion (represented as Ox^{2-}).

The formation-constant expression is

$$K_f = \frac{[\text{Co}(\text{Ox})_3]^{4-}}{[\text{Co}^{2+}][\text{Ox}^{2-}]^3}$$

Because K_f is so large, we can assume that essentially all the Co^{2+} is converted to the oxalato complex. Under that assumption, the final concentration of $[\text{Co}(\text{Ox})_3]^{4-}$ is 0.0010 M and that of oxalate ion is $[\text{Ox}^{2-}] = (0.040) - 3(0.0010) = 0.037\text{ M}$ (three Ox^{2-} ions react with each Co^{2+} ion). We then have

$$[\text{Co}^{2+}] = x\text{ M}, [\text{Ox}^{2-}] \cong 0.037\text{ M}, [[\text{Co}(\text{Ox})_3]^{4-}] \cong 0.0010\text{ M}$$

Inserting these values into the equilibrium-constant expression, we have

$$K_f = \frac{(0.0010)}{x(0.037)^3} = 5 \times 10^9$$

Solving for x , we obtain $4 \times 10^{-9}\text{ M}$. From this, we see that the oxalate has complexed all but a tiny fraction of the Co^{2+} in solution.

CHAPTER SUMMARY AND KEY TERMS

SECTION 23.1. Metallic elements occur in nature in **minerals**, which are solid inorganic compounds found in nature. **Metallurgy** is the science and technology of extracting metals from the earth and processing them for further use. Transition metals are characterized by incomplete filling of the d orbitals. The presence of d electrons in transition elements leads to multiple oxidation states. As we proceed through the transition metals in a given row of the periodic table, the attraction between the nucleus and the valence electrons increases more markedly for d electrons than for s electrons. As a result, the later transition elements in a period tend to have lower oxidation states.

The atomic and ionic radii of period 5 transition metals are larger than those of period 4 metals. The transition metals of periods 5 and 6 have comparable atomic and ionic radii and are also similar in other properties. This similarity is due to the **lanthanide contraction**.

The presence of unpaired electrons in valence orbitals leads to magnetic behavior in transition metals and their compounds. In **ferromagnetic**, **ferrimagnetic**, and **antiferromagnetic** substances the unpaired electron spins on atoms in a solid are affected by spins on neighboring atoms. In a ferromagnetic substance the spins all point in the same direction. In an antiferromagnetic substance the spins point in opposite directions and cancel one another. In a ferrimagnetic substance the spins point in opposite directions but do not fully cancel. Ferromagnetic and ferrimagnetic substances are used to make permanent magnets.

SECTION 23.2 **Coordination compounds** are substances that contain **metal complexes**. Metal complexes contain metal ions bonded to several surrounding anions or molecules known as **ligands**. The metal ion and its ligands make up the **coordination sphere** of the complex. The number of atoms attached to the metal ion is the **coordination number** of the metal ion. The most common coordination numbers are 4 and 6; the most common coordination geometries are tetrahedral, square planar, and octahedral.

SECTION 23.3 Ligands that occupy only one site in a coordination sphere are called **monodentate ligands**. The atom of the ligand that bonds to the metal ion is the **donor atom**. Ligands that have two donor atoms are **bidentate ligands**. **Polydentate ligands** have three or more

donor atoms. Bidentate and polydentate ligands are also called **chelating agents**. In general, chelating agents form more stable complexes than do related monodentate ligands, an observation known as the **chelate effect**. Many biologically important molecules, such as the **porphyrins**, are complexes of chelating agents. A related group of plant pigments known as **chlorophylls** is important in **photosynthesis**, the process by which plants use solar energy to convert CO_2 and H_2O into carbohydrates.

SECTION 23.4 In naming coordination compounds, the number and type of ligands attached to the metal ion are specified, as is the oxidation state of the metal ion. **Isomers** are compounds with the same composition but different arrangements of atoms and therefore different properties. **Structural isomers** differ in the bonding arrangements of the ligands. **Linkage isomerism** occurs when a ligand can coordinate to a metal ion through either of two donor atoms. **Coordination-sphere isomers** contain different ligands in the coordination sphere. **Stereoisomers** are isomers with the same chemical bonding arrangements but different spatial arrangements of ligands. The most common forms of stereoisomerism are **geometric isomerism** and **optical isomerism**. Geometric isomers differ from one another in the relative locations of donor atoms in the coordination sphere; the most common are *cis-trans* isomers. Optical isomers are nonsuperimposable mirror images of each other. Geometric isomers differ from one another in their chemical and physical properties; optical isomers, or **enantiomers**, are **chiral**, however, meaning that they have a specific “handedness” and differ only in the presence of a chiral environment. Optical isomers can be distinguished from one another by their interactions with plane-polarized light; solutions of one isomer rotate the plane of polarization to the right (**dextrorotatory**), and solutions of its mirror image rotate the plane to the left (**levorotatory**). Chiral molecules, therefore, are **optically active**. A 50–50 mixture of two optical isomers does not rotate plane-polarized light and is said to be **racemic**.

SECTION 23.5 A substance has a particular color because it either reflects or transmits light of that color or absorbs light of the **complementary color**. The amount of light absorbed by a sample as a

function of wavelength is known as its **absorption spectrum**. The light absorbed provides the energy to excite electrons to higher-energy states.

It is possible to determine the number of unpaired electrons in a complex from its degree of paramagnetism. Compounds with no unpaired electrons are diamagnetic.

SECTION 23.6 Crystal-field theory successfully accounts for many properties of coordination compounds, including their color and magnetism. In crystal-field theory, the interaction between metal ion and ligand is viewed as electrostatic. Because some d orbitals point right at the ligands whereas others point between them, the ligands split the energies of the metal d orbitals. For an octahedral complex, the d orbitals are split into a lower-energy set of three degenerate orbitals (the t_2 set) and a higher-energy set of two degenerate orbitals (the e set). Visible light can cause a **d - d transition**, in which an electron is excited from a lower-energy d orbital to a higher-energy d orbital. The

spectrochemical series lists ligands in order of their ability to increase the split in d -orbital energies in octahedral complexes.

Strong-field ligands create a splitting of d -orbital energies that is large enough to overcome the **spin-pairing energy**. The d electrons then preferentially pair up in the lower-energy orbitals, producing a **low-spin complex**. When the ligands exert a weak crystal field, the splitting of the d orbitals is small. The electrons then occupy the higher-energy d orbitals in preference to pairing up in the lower-energy set, producing a **high-spin complex**.

Crystal-field theory also applies to tetrahedral and square-planar complexes, which leads to different d -orbital splitting patterns. In a tetrahedral crystal field, the splitting of the d orbitals results in a higher-energy t_2 set and a lower-energy e set, the opposite of the octahedral case. The splitting by a tetrahedral crystal field is much smaller than that by an octahedral crystal field, so tetrahedral complexes are always high-spin complexes.

KEY SKILLS

- Describe the periodic trends in radii and oxidation states of the transition-metal ions, including the origin and effect of the lanthanide contraction. (Section 23.1)
- Determine the oxidation number and number of d electrons for metal ions in complexes. (Section 23.2)
- Distinguish between chelating and nonchelating ligands. (Section 23.3)
- Name coordination compounds given their formula and write their formula given their name. (Section 23.4)
- Recognize and draw the geometric isomers of a complex. (Section 23.4)
- Recognize and draw the optical isomers of a complex. (Section 23.4)
- Use crystal-field theory to explain the colors and to determine the number of unpaired electrons in a complex. (Sections 23.5 and 23.6)

EXERCISES

VISUALIZING CONCEPTS

- 23.1** This chart shows the variation in an important property of the metals from K through Ge. Is the property atomic radius, electronegativity, or first ionization energy? Explain your choice. [Section 23.1]

- 23.2** (a) Draw the structure for $\text{Pt}(\text{en})\text{Cl}_2$. (b) What is the coordination number for platinum in this complex, and what is the coordination geometry? (c) What is the oxidation state of the platinum? [Section 23.2]
- 23.3** Draw the Lewis structure for the ligand shown in the next column. (a) Which atoms can serve as donor atoms? Classify this ligand as monodentate, bidentate, or tridentate. (b) How many of these ligands are needed to fill the coordination sphere in an octahedral complex? [Section 23.2]

- 23.4** The complex ion shown here has a 1- charge. Name the complex ion. [Section 23.4]

23.5 There are two geometric isomers of octahedral complexes of the type MA_3X_3 , where M is a metal and A and X are monodentate ligands. Of the complexes shown here, which are identical to (1) and which are the geometric isomers of (1)? [Section 23.4]

23.6 Which of the complexes shown here are chiral? Explain. [Section 23.4]

23.7 The solutions shown here each have an absorption spectrum with a single absorption peak like that shown in Figure 23.26. What color does each solution absorb most strongly? [Section 23.5]

THE TRANSITION METALS (section 23.1)

- 23.11 Explain the lanthanide contraction, and describe how it affects the properties of the transition-metal elements.
- 23.12 Sketch a plot of atomic radius versus number of valence d electrons for the period 5 transition metals, and explain the trend.
- 23.13 The +2 oxidation state is common for almost all the transition metals. Suggest an explanation.
- 23.14 No compounds are known in which scandium is in the +2 oxidation state. Suggest an explanation.
- 23.15 Write out the ground-state electron configurations of (a) Ti^{3+} , (b) Ru^{2+} , (c) Au^{3+} , (d) Mn^{4+} .
- 23.16 How many electrons are in the valence d orbitals in these transition-metal ions? (a) Co^{3+} , (b) Cu^+ , (c) Cd^{2+} , (d) Os^{3+} .
- 23.17 Explain the difference between a diamagnetic substance and a paramagnetic substance.

23.8 Which of these crystal-field splitting diagrams represents: (a) a weak-field octahedral complex of Fe^{3+} , (b) a strong-field octahedral complex of Fe^{3+} , (c) a tetrahedral complex of Fe^{3+} , (d) a tetrahedral complex of Ni^{2+} ? (The diagrams do not indicate the relative magnitudes of Δ .) [Section 23.6]

23.9 In the linear crystal field shown here, the negative charges are on the z -axis. Using Figure 23.28 as a guide, predict which d orbital has lobes closest to the charges. Which two have lobes farthest from the charges? Predict the crystal-field splitting of the d orbitals in linear complexes. [Section 23.6]

23.10 Two $Fe(II)$ complexes are both low spin but have different ligands. A solution of one is green and a solution of the other is red. Which solution is likely to contain the complex that has the stronger-field ligand? [Section 23.6]

- 23.11 Explain the lanthanide contraction, and describe how it affects the properties of the transition-metal elements.
- 23.12 Sketch a plot of atomic radius versus number of valence d electrons for the period 5 transition metals, and explain the trend.
- 23.13 The +2 oxidation state is common for almost all the transition metals. Suggest an explanation.
- 23.14 No compounds are known in which scandium is in the +2 oxidation state. Suggest an explanation.
- 23.15 Write out the ground-state electron configurations of (a) Ti^{3+} , (b) Ru^{2+} , (c) Au^{3+} , (d) Mn^{4+} .
- 23.16 How many electrons are in the valence d orbitals in these transition-metal ions? (a) Co^{3+} , (b) Cu^+ , (c) Cd^{2+} , (d) Os^{3+} .
- 23.17 Explain the difference between a diamagnetic substance and a paramagnetic substance.
- 23.18 Distinguish among a ferromagnetic substance, an antiferromagnetic substance, and a ferrimagnetic substance.
- 23.19 What kind of magnetism is exhibited by this diagram:
-
- Put in vertical magnetic field
- Magnetic field
- 23.20 The most important oxides of iron are magnetite, Fe_3O_4 , and hematite, Fe_2O_3 . (a) What are the oxidation states of iron in these compounds? (b) One of these iron oxides is ferrimagnetic, and the other is antiferromagnetic. Which iron oxide is likely to show which type of magnetism? Explain.

TRANSITION-METAL COMPLEXES (section 23.2)

- 23.21** (a) What is the difference between Werner's concepts of *primary valence* and *secondary valence*? What terms do we now use for these concepts? (b) Why can the NH_3 molecule serve as a ligand but the BH_3 molecule cannot?
- 23.22** (a) What is the meaning of the term *coordination number* as it applies to metal complexes? (b) Give an example of a ligand that is neutral and one that is negatively charged. (c) Would you expect ligands that are positively charged to be common? Explain. (d) What type of chemical bonding is characteristic of coordination compounds? Illustrate with the compound $\text{Co}(\text{NH}_3)_6\text{Cl}_3$. (e) What are the most common coordination numbers for metal complexes?
- 23.23** A complex is written as $\text{NiBr}_2 \cdot 6 \text{NH}_3$. (a) What is the oxidation state of the Ni atom in this complex? (b) What is the likely coordination number for the complex? (c) If the complex is treated with excess $\text{AgNO}_3(\text{aq})$, how many moles of AgBr will precipitate per mole of complex?
- 23.24** A certain complex of metal M is formulated as $\text{MCl}_3 \cdot 3 \text{H}_2\text{O}$. The coordination number of the complex is not known but is expected to be 4 or 6. (a) Would conductivity measurements provide information about the coordination number? (b) In using conductivity measurements to test which ligands are bound to the metal ion, what assumption is made about the rate at which ligands enter or leave the coordination sphere of

the metal? (c) Suppose you experimentally determine that this complex exists in aqueous solution as a single species. Suggest a likely coordination number and the number and type of each ligand.

- 23.25** Indicate the coordination number of the metal and the oxidation number of the metal as well as the number and type of each donor atom of the ligands for each of the following complexes:
- $\text{Na}_2[\text{CdCl}_4]$
 - $\text{K}_2[\text{MoOCl}_4]$
 - $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}$
 - $[\text{Ni}(\text{CN})_5]^{3-}$
 - $\text{K}_3[\text{V}(\text{C}_2\text{O}_4)_3]$
 - $[\text{Zn}(\text{en})_2]\text{Br}_2$
- 23.26** Indicate the coordination number of the metal and the oxidation number of the metal as well as the number and type of each donor atom of the ligands for each of the following complexes:
- $\text{K}_3[\text{Co}(\text{CN})_6]$
 - $\text{Na}_2[\text{CdBr}_4]$
 - $[\text{Pt}(\text{en})_3](\text{ClO}_4)_4$
 - $[\text{Co}(\text{en})_2(\text{C}_2\text{O}_4)]^+$
 - $\text{NH}_4[\text{Cr}(\text{NH}_3)_2(\text{NCS})_4]$
 - $[\text{Cu}(\text{bipy})_2]\text{I}$

COMMON LIGANDS IN COORDINATION CHEMISTRY (section 23.3)

- 23.27** (a) What is the difference between a monodentate ligand and a bidentate ligand? (b) How many bidentate ligands are necessary to fill the coordination sphere of a six-coordinate complex? (c) You are told that a certain molecule can serve as a tridentate ligand. Based on this statement, what do you know about the molecule?
- 23.28** For each of the following polydentate ligands, determine (i) the maximum number of coordination sites that the ligand can occupy on a single metal ion and (ii) the number and type of donor atoms in the ligand: (a) ethylenediamine (en), (b) bipyridine (bipy), (c) the oxalate anion ($\text{C}_2\text{O}_4^{2-}$), (d) the 2- ion of the porphine molecule (Figure 23.13); (e) $[\text{EDTA}]^{4-}$.
- 23.29** Polydentate ligands can vary in the number of coordination positions they occupy. In each of the following, identify the polydentate ligand present and indicate the probable number of coordination positions it occupies:
- $[\text{Co}(\text{NH}_3)_4(o\text{-phen})]\text{Cl}_3$
 - $[\text{Cr}(\text{C}_2\text{O}_4)(\text{H}_2\text{O})_4]\text{Br}$
 - $[\text{Cr}(\text{EDTA})(\text{H}_2\text{O})]^-$
 - $[\text{Zn}(\text{en})_2](\text{ClO}_4)_2$
- 23.30** Indicate the likely coordination number of the metal in each of the following complexes:
- $[\text{Rh}(\text{bipy})_3](\text{NO}_3)_3$
 - $\text{Na}_3[\text{Co}(\text{C}_2\text{O}_4)_2\text{Cl}_2]$
 - $[\text{Cr}(o\text{-phen})_3](\text{CH}_3\text{COO})_3$
 - $\text{Na}_2[\text{Co}(\text{EDTA})\text{Br}]$
- 23.31** (a) What is meant by the term *chelate effect*? (b) What thermodynamic factor is generally responsible for the chelate effect? (c) Why are polydentate ligands often called *sequestering agents*?

- 23.32** *Pyridine* ($\text{C}_5\text{H}_5\text{N}$), abbreviated py, is the molecule

- (a) Why is pyridine referred to as a monodentate ligand? (b) For the equilibrium reaction

what would you predict for the magnitude of the equilibrium constant? Explain your answer.

- 23.33** Is the following ligand a chelating one? Explain.

- 23.34** What is the geometry about the metal center in this complex? Would you expect this complex to have counterions? Explain.

NOMENCLATURE AND ISOMERISM IN COORDINATION CHEMISTRY (section 23.4)

- 23.35** Write the formula for each of the following compounds, being sure to use brackets to indicate the coordination sphere:
- hexaamminechromium(III) nitrate
 - tetraamminecarbonatocobalt(III) sulfate
 - dichlorobis(ethylenediamine)platinum(IV) bromide
 - potassium diaquatetrabromovanadate(III)
 - bis(ethylenediamine)zinc(II) tetraiodomercurate(II)
- 23.36** Write the formula for each of the following compounds, being sure to use brackets to indicate the coordination sphere:
- tetraaquadibromomanganese(III) perchlorate
 - bis(bipyridyl)cadmium(II) chloride
 - potassium tetrabromo(*ortho*-phenanthroline)-cobaltate(III)
 - cesium diamminetetracyanochromate(III)
 - tris(ethylenediamine)rhodium(III) tris(oxalato)-cobaltate(III)
-
- 23.37** Write the names of the following compounds, using the standard nomenclature rules for coordination complexes:
- $[\text{Rh}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}$
 - $\text{K}_2[\text{TiCl}_6]$
 - MoOCl_4
 - $[\text{Pt}(\text{H}_2\text{O})_4(\text{C}_2\text{O}_4)]\text{Br}_2$
- 23.38** Write names for the following coordination compounds:
- $[\text{Cd}(\text{en})\text{Cl}_2]$
 - $\text{K}_4[\text{Mn}(\text{CN})_6]$
 - $[\text{Cr}(\text{NH}_3)_5\text{CO}_3]\text{Cl}$
 - $[\text{Ir}(\text{NH}_3)_4(\text{H}_2\text{O})_2](\text{NO}_3)_3$
-
- 23.39** By writing formulas or drawing structures related to any one of these three complexes,
 $[\text{Co}(\text{NH}_3)_4\text{Br}_2]\text{Cl}$
 $[\text{Pd}(\text{NH}_3)_2(\text{ONO})_2]$
 $\text{cis}-[\text{V}(\text{en})_2\text{Cl}_2]^+$,
 illustrate (a) geometric isomerism, (b) linkage isomerism, (c) optical isomerism, (d) coordination-sphere isomerism.
- 23.40** (a) Draw the two linkage isomers of $[\text{Co}(\text{NH}_3)_5\text{SCN}]^{2+}$. (b) Draw the two geometric isomers of $[\text{Co}(\text{NH}_3)_3\text{Cl}_3]^{2+}$. (c) Two compounds with the formula $\text{Co}(\text{NH}_3)_5\text{ClBr}$ can be prepared. Use structural formulas to show how they differ. What kind of isomerism does this illustrate?
-
- 23.41** A four-coordinate complex MA_2B_2 is prepared and found to have two different isomers. Is it possible to determine from this information whether the complex is square planar or tetrahedral? If so, which is it?
- 23.42** Consider an octahedral complex MA_3B_3 . How many geometric isomers are expected for this compound? Will any of the isomers be optically active? If so, which ones?
-
- 23.43** Sketch all the possible stereoisomers of (a) tetrahedral $[\text{Cd}(\text{H}_2\text{O})_2\text{Cl}_2]$, (b) square-planar $[\text{IrCl}_2(\text{PH}_3)_2]^-$, (c) octahedral $[\text{Fe}(\text{o-phen})_2\text{Cl}_2]^+$.
- 23.44** Sketch all the possible stereoisomers of (a) $[\text{Rh}(\text{bipy})(\text{o-phen})_2]^{3+}$, (b) $[\text{Co}(\text{NH}_3)_3(\text{bipy})\text{Br}]^{2+}$, (c) square-planar $[\text{Pd}(\text{en})(\text{CN})_2]$.

COLOR AND MAGNETISM IN COORDINATION CHEMISTRY; CRYSTAL-FIELD THEORY (sections 23.5 and 23.6)

- 23.45** (a) Can we see light that is 300 nm in wavelength? 500 nm in wavelength? (b) What is meant by the term *complementary color*? (c) What is the significance of complementary colors in understanding the colors of metal complexes? (d) If a complex absorbs light at 610 nm, what is the energy of this absorption in kJ/mol?
- 23.46** (a) A complex absorbs light in the range of 200–300 nm. Do you expect it to have visible color? (b) A solution of a compound appears green. Does this observation necessarily mean that all colors of visible light other than green are absorbed by the solution? Explain. (c) What information is usually presented in a *visible absorption spectrum* of a compound? (d) What energy is associated with an absorption at 440 nm in kJ/mol?
-
- 23.47** Is it possible for a low-spin octahedral Fe(II) complex to be paramagnetic? Explain.
- 23.48** If a transition-metal complex has an even number of valence d electrons, does it necessarily mean that the complex is diamagnetic? Explain.
-
- 23.49** In crystal-field theory, ligands are modeled as if they are point negative charges. What is the basis of this assumption, and how does it relate to the nature of metal–ligand bonds?
- 23.50** Explain why the d_{xy} , d_{xz} , and d_{yz} orbitals lie lower in energy than the d_{z^2} and $d_{x^2-y^2}$ orbitals in the presence of an octahedral arrangement of ligands about the central metal ion.
-
- 23.51** (a) Sketch a diagram that shows the definition of the *crystal-field splitting energy* (Δ) for an octahedral crystal field. (b) What is the relationship between the magnitude of Δ and the energy of the $d-d$ transition for a d^1 complex? (c) Calculate Δ in kJ/mol if a d^1 complex has an absorption maximum at 545 nm.
- 23.52** As shown in Figure 23.26, the $d-d$ transition of $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$ produces an absorption maximum at a wavelength of about 500 nm. (a) What is the magnitude of Δ for $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$ in kJ/mol? (b) What is the *spectrochemical series*? How would the magnitude of Δ change if the H_2O ligands in $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$ were replaced with NH_3 ligands?
-
- 23.53** Explain why many cyano complexes of divalent transition-metal ions are yellow, whereas many aqua complexes of these ions are blue or green.
- 23.54** The $[\text{Ni}(\text{H}_2\text{O})_6]^{2+}$ ion has an absorption maximum at about 725 nm, whereas the $[\text{Ni}(\text{NH}_3)_6]^{2+}$ ion absorbs at about 570 nm. Predict the color of a solution of each ion. (b) The $[\text{Ni}(\text{en})_3]^{2+}$ ion absorption maximum occurs at about 545 nm, and that of the $[\text{Ni}(\text{bipy})_3]^{2+}$ ion occurs at about 520 nm. From these data, indicate the relative strengths of the ligand fields created by the four ligands involved.
-
- 23.55** Give the number of (valence) d electrons associated with the central metal ion in each of the following complexes: (a) $\text{K}_3[\text{TiCl}_6]$, (b) $\text{Na}_3[\text{Co}(\text{NO}_2)_6]$, (c) $[\text{Ru}(\text{en})_3]\text{Br}_3$, (d) $[\text{Mo}(\text{EDTA})]\text{ClO}_4$, (e) $\text{K}_3[\text{ReCl}_6]$.

- 23.56** Give the number of (valence) d electrons associated with the central metal ion in each of the following complexes: (a) $K_3[Fe(CN)_6]$, (b) $[Mn(H_2O)_6](NO_3)_2$, (c) $Na[Ag(CN)_2]$, (d) $[Cr(NH_3)_4Br_2]ClO_4$, (e) $[Sr(EDTA)]^{2-}$.
- 23.57** A classmate says, "A weak-field ligand usually means the complex is high spin." Is your classmate correct? Explain.
- 23.58** A classmate says, "A strong-field ligand means that the ligand binds strongly to the metal ion." Is your classmate correct? Explain.
- 23.59** For each of the following metals, write the electronic configuration of the atom and its $2+$ ion: (a) Mn, (b) Ru, (c) Rh. Draw the crystal-field energy-level diagram for the d orbitals of an octahedral complex, and show the placement of the d electrons for each $2+$ ion, assuming a strong-field complex. How many unpaired electrons are there in each case?
- 23.60** For each of the following metals, write the electronic configuration of the atom and its $3+$ ion: (a) Ru, (b) Mo, (c) Co. Draw the crystal-field energy-level diagram for the d orbitals of an octahedral complex, and show the placement of the d electrons for each $3+$ ion, assuming a weak-field complex. How many unpaired electrons are there in each case?
- 23.61** Draw the crystal-field energy-level diagrams and show the placement of d electrons for each of the following: (a) $[Cr(H_2O)_6]^{2+}$ (four unpaired electrons), (b) $[Mn(H_2O)_6]^{2+}$ (high spin), (c) $[Ru(NH_3)_5H_2O]^{2+}$ (low spin), (d) $[IrCl_6]^{2-}$ (low spin), (e) $[Cr(en)_3]^{3+}$, (f) $[NiF_6]^{4-}$.
- 23.62** Draw the crystal-field energy-level diagrams and show the placement of electrons for the following complexes: (a) $[VCl_6]^{3-}$, (b) $[FeF_6]^{3-}$ (a high-spin complex), (c) $[Ru(bipy)_3]^{3+}$ (a low-spin complex), (d) $[NiCl_4]^{2-}$ (tetrahedral), (e) $[PtBr_6]^{2-}$, (f) $[Ti(en)_3]^{2+}$.
- 23.63** The complex $[Mn(NH_3)_6]^{2+}$ contains five unpaired electrons. Sketch the energy-level diagram for the d orbitals, and indicate the placement of electrons for this complex ion. Is the ion a high-spin or a low-spin complex?
- 23.64** The ion $[Fe(CN)_6]^{3-}$ has one unpaired electron, whereas $[Fe(NCS)_6]^{3-}$ has five unpaired electrons. From these results, what can you conclude about whether each complex is high spin or low spin? What can you say about the placement of NCS^- in the spectrochemical series?

ADDITIONAL EXERCISES

23.65 The *Curie temperature* is the temperature at which a ferromagnetic solid switches from ferromagnetic to paramagnetic, and for nickel, the Curie temperature is 354°C . Knowing this, you tie a string to two paper clips made of nickel and hold the paper clips near a permanent magnet. The magnet attracts the paper clips, as shown in the photograph on the left. Now you heat one of the paper clips with a cigarette lighter, and the clip drops (right photograph). Explain what happened.

- 23.66** Explain why the transition metals in periods 5 and 6 have nearly identical radii in each group.
- 23.67** Based on the molar conductance values listed here for the series of platinum(IV) complexes, write the formula for each complex so as to show which ligands are in the coordination sphere of the metal. By way of example, the molar conductances of 0.050 M $NaCl$ and $BaCl_2$ are 107 ohm^{-1} and 197 ohm^{-1} , respectively.

Complex	Molar Conductance (ohm^{-1})* of 0.050 M Solution
$Pt(NH_3)_6Cl_4$	523
$Pt(NH_3)_4Cl_4$	228
$Pt(NH_3)_3Cl_4$	97
$Pt(NH_3)_2Cl_4$	0
$KPt(NH_3)Cl_5$	108

*The ohm is a unit of resistance; conductance is the inverse of resistance.

- 23.68** (a) A compound with formula $RuCl_3 \cdot 5H_2O$ is dissolved in water, forming a solution that is approximately the same color as the solid. Immediately after forming the solution, the addition of excess $AgNO_3(aq)$ forms 2 mol of solid $AgCl$ per mole of complex. Write the formula for the compound, showing which ligands are likely to be present in the coordination sphere. (b) After a solution of $RuCl_3 \cdot 5H_2O$ has stood for about a year, addition of $AgNO_3(aq)$ precipitates 3 mol of $AgCl$ per mole of complex. What has happened in the ensuing time?
- 23.69** Sketch the structure of the complex in each of the following compounds and give the full compound name: (a) *cis*- $[Co(NH_3)_4(H_2O)_2](NO_3)_2$, (b) $Na_2[Ru(H_2O)Cl_5]$, (c) *trans*- $NH_4[Co(C_2O_4)_2(H_2O)_2]$, (d) *cis*- $[Ru(en)_2Cl_2]$
- 23.70** (a) Which complex ions in Exercise 23.69 have a mirror plane? (b) Will any of the complexes be optically active? Explain.
- 23.71** The molecule *dimethylphosphinoethane* $[(CH_3)_2PCH_2CH_2P(CH_3)_2]$, which is abbreviated *dmpe* is used as a ligand for some complexes that serve as catalysts. A complex that contains this ligand is $Mo(CO)_4(dmpe)$. (a) Draw the Lewis structure for *dmpe*, and compare it with ethylenediamine as a coordinating ligand. (b) What is the oxidation state of Mo in $Na_2[Mo(CN)_2(CO)_2(dmpe)]$? (c) Sketch the structure of the $[Mo(CN)_2(CO)_2(dmpe)]^{2-}$ ion, including all the possible isomers.

23.72 Although the *cis* configuration is known for $[\text{Pt}(\text{en})\text{Cl}_2]$, no *trans* form is known. (a) Explain why the *trans* compound is not possible. (b) Would $\text{NH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}_2$ be more likely than en ($\text{NH}_2\text{CH}_2\text{CH}_2\text{NH}_2$) to form the *trans* compound? Explain.

23.73 The acetylacetonate ion forms very stable complexes with many metallic ions. It acts as a bidentate ligand, coordinating to the metal at two adjacent positions. Suppose that one of the CH_3 groups of the ligand is replaced by a CF_3 group, as shown here,

Sketch all possible isomers for the complex with three tfac ligands on cobalt(III). (You can use the symbol $\bullet\bigcirc$ to represent the ligand.)

23.74 Give brief statements about the relevance of the following complexes in living systems: (a) hemoglobin, (b) chlorophylls, (c) siderophores.

23.75 Write balanced chemical equations to represent the following observations. (In some instances the complex involved has been discussed previously in the text.) (a) Solid silver chloride dissolves in an excess of aqueous ammonia. (b) The green complex $[\text{Cr}(\text{en})_2\text{Cl}_2]\text{Cl}$, on treatment with water over a long time, converts to a brown-orange complex. Reaction of AgNO_3 with a solution of the product precipitates 3 mol of AgCl per mole of Cr present. (Write two chemical equations.) (c) When an NaOH solution is added to a solution of $\text{Zn}(\text{NO}_3)_2$, a precipitate forms. Addition of excess NaOH solution causes the precipitate to dissolve. (Write two chemical equations.) (d) A pink solution of $\text{Co}(\text{NO}_3)_2$ turns deep blue on addition of concentrated hydrochloric acid.

23.76 Some metal complexes have a coordination number of 5. One such complex is $\text{Fe}(\text{CO})_5$, which adopts a *trigonal bipyramidal* geometry (see Figure 9.8). (a) Write the name for $\text{Fe}(\text{CO})_5$, using the nomenclature rules for coordination compounds. (b) What is the oxidation state of Fe in this compound? (c) Suppose one of the CO ligands is replaced with a CN^- ligand, forming $[\text{Fe}(\text{CO})_4(\text{CN})]^-$. How many geometric isomers would you predict this complex could have?

23.77 Which of the following objects is chiral: (a) a left shoe, (b) a slice of bread, (c) a wood screw, (d) a molecular model of $\text{Zn}(\text{en})\text{Cl}_2$, (e) a typical golf club?

23.78 The complexes $[\text{V}(\text{H}_2\text{O})_6]^{3+}$ and $[\text{VF}_6]^{3-}$ are both known. (a) Draw the *d*-orbital energy-level diagram for V(III) octahedral complexes. (b) What gives rise to the colors of these complexes? (c) Which of the two complexes would you expect to absorb light of higher energy? Explain.

[23.79] One of the more famous species in coordination chemistry is the Creutz–Taube complex,

It is named for the two scientists who discovered it and initially studied its properties. The central ligand is pyrazine, a planar six-membered ring with nitrogens at opposite sides. (a) How can you account for the fact that the complex, which has only neutral ligands, has an odd overall charge? (b) The metal is in a low-spin configuration in both cases. Assuming octahedral coordination, draw the *d*-orbital energy-level diagram for each metal. (c) In many experiments the two metal ions appear to be in exactly equivalent states. Can you think of a reason that this might appear to be so, recognizing that electrons move very rapidly compared to nuclei?

23.80 Solutions of $[\text{Co}(\text{NH}_3)_6]^{2+}$, $[\text{Co}(\text{H}_2\text{O})_6]^{2+}$ (both octahedral), and $[\text{CoCl}_4]^{2-}$ (tetrahedral) are colored. One is pink, one is blue, and one is yellow. Based on the spectrochemical series and remembering that the energy splitting in tetrahedral complexes is normally much less than that in octahedral ones, assign a color to each complex.

23.81 Oxyhemoglobin, with an O_2 bound to iron, is a low-spin Fe(II) complex; deoxyhemoglobin, without the O_2 molecule, is a high-spin complex. (a) Assuming that the coordination environment about the metal is octahedral, how many unpaired electrons are centered on the metal ion in each case? (b) What ligand is coordinated to the iron in place of O_2 in deoxyhemoglobin? (c) Explain in a general way why the two forms of hemoglobin have different colors (hemoglobin is red, whereas deoxyhemoglobin has a bluish cast). (d) A 15-minute exposure to air containing 400 ppm of CO causes about 10% of the hemoglobin in the blood to be converted into the carbon monoxide complex, called carboxyhemoglobin. What does this suggest about the relative equilibrium constants for binding of carbon monoxide and O_2 to hemoglobin? (e) CO is a strong-field ligand. What color might you expect carboxyhemoglobin to be?

[23.82] Consider the tetrahedral anions VO_4^{3-} (orthovanadate ion), CrO_4^{2-} (chromate ion), and MnO_4^- (permanganate ion). (a) These anions are *isoelectronic*. What does this statement mean? (b) Would you expect these anions to exhibit *d-d* transitions? Explain. (c) As mentioned in “A Closer Look” on charge-transfer color, the violet color of MnO_4^- is due to a *ligand-to-metal charge transfer* (LMCT) transition. What is meant by this term? (d) The LMCT transition in MnO_4^- occurs at a wavelength of 565 nm. The CrO_4^{2-} ion is yellow. Is the wavelength of the LMCT transition for chromate larger or smaller than that for MnO_4^- ? Explain. (e) The VO_4^{3-} ion is colorless. Do you expect the light absorbed by the LMCT to fall in the UV or the IR region of the electromagnetic spectrum? Explain your reasoning.

[23.83] Given the colors observed for VO_4^{3-} (orthovanadate ion), CrO_4^{2-} (chromate ion), and MnO_4^- (permanganate ion) (see Exercise 23.82), what can you say about how the energy separation between the ligand orbitals and the empty *d* orbitals changes as a function of the oxidation state of the transition metal at the center of the tetrahedral anion?

[23.84] The red color of ruby is due to the presence of Cr(III) ions at octahedral sites in the close-packed oxide lattice of Al_2O_3 . Draw the crystal-field splitting diagram for Cr(III) in this environment. Suppose that the ruby crystal is subjected to high pressure. What do you predict for the variation in the wavelength of absorption of the ruby as a function of pressure? Explain.

- 23.85** In 2001, chemists at SUNY-Stony Brook succeeded in synthesizing the complex *trans*-[Fe(CN)₄(CO)₂]²⁻, which could be a model of complexes that may have played a role in the origin of life. (a) Sketch the structure of the complex. (b) The complex is isolated as a sodium salt. Write the complete name of this salt. (c) What is the oxidation state of Fe in this complex? How many *d* electrons are associated with the Fe in this complex? (d) Would you expect this complex to be high spin or low spin? Explain.
- [23.86]** When Alfred Werner was developing the field of coordination chemistry, it was argued by some that the optical activity he observed in the chiral complexes he had prepared was because of the presence of carbon atoms in the molecule. To disprove this argument, Werner synthesized a chiral complex of cobalt that had no carbon atoms in it, and he was able to resolve it into its enantiomers. Design a cobalt(III) complex that would be chiral if it could be synthesized and that contains no carbon atoms. (It may not be possible to synthesize the complex you design, but we won't worry about that for now.)
- 23.87** Generally speaking, for a given metal and ligand, the stability of a coordination compound is greater for the metal in the +3 rather than in the +2 oxidation state (for metals that

form stable +3 ions in the first place). Suggest an explanation, keeping in mind the Lewis acid–base nature of the metal–ligand bond.

- 23.88** Many trace metal ions exist in the blood complexed with amino acids or small peptides. The anion of the amino acid glycine (gly),

can act as a bidentate ligand, coordinating to the metal through nitrogen and oxygen atoms. How many isomers are possible for (a) [Zn(gly)₂] (tetrahedral), (b) [Pt(gly)₂] (square planar), (c) [Co(gly)₃] (octahedral)? Sketch all possible isomers. Use the symbol N_O to represent the ligand.

- [23.89]** Suppose that a transition-metal ion was in a lattice in which it was in contact with just two nearby anions, located on opposite sides of the metal. Diagram the splitting of the metal *d* orbitals that would result from such a crystal field. Assuming a strong field, how many unpaired electrons would you expect for a metal ion with six *d* electrons? (*Hint*: Consider the linear axis to be the *z*-axis)

INTEGRATIVE EXERCISES

- [23.90]** Metallic elements are essential components of many important enzymes operating within our bodies. *Carbonic anhydrase*, which contains Zn²⁺ in its active site, is responsible for rapidly interconverting dissolved CO₂ and bicarbonate ion, HCO₃⁻. The zinc in carbonic anhydrase is tetrahedrally coordinated by three neutral nitrogen-containing groups and a water molecule. The coordinated water molecule has a p*K*_a of 7.5, which is crucial for the enzyme's activity. (a) Draw the active site geometry for the Zn(II) center in carbonic anhydrase, just writing "N" for the three neutral nitrogen ligands from the protein. (b) Compare the p*K*_a of carbonic anhydrase's active site with that of pure water; which species is more acidic? (c) When the coordinated water to the Zn(II) center in carbonic anhydrase is deprotonated, what ligands are bound to the Zn(II) center? Assume the three nitrogen ligands are unaffected. (d) The p*K*_a of [Zn(H₂O)₆]²⁺ is 10. Suggest an explanation for the difference between this p*K*_a and that of carbonic anhydrase. (e) Would you expect carbonic anhydrase to have a deep color, like hemoglobin and other metal-ion containing proteins do? Explain.
- 23.91** Two different compounds have the formulation CoBr(SO₄) · 5 NH₃. Compound A is dark violet, and compound B is red-violet. When compound A is treated with AgNO₃(aq), no reaction occurs, whereas compound B reacts with AgNO₃(aq) to form a white precipitate. When compound A is treated with BaCl₂(aq), a white precipitate is formed, whereas compound B has no reaction with BaCl₂(aq). (a) Is Co in the same oxidation state in these complexes? (b) Explain the reactivity of compounds A and B with AgNO₃(aq) and BaCl₂(aq). (c) Are compounds A and B isomers of one another? If so, which category from Figure 23.19 best describes the isomerism observed for these complexes? (d) Would compounds A and B be expected to be strong electrolytes, weak electrolytes, or nonelectrolytes?

- 23.92** A manganese complex formed from a solution containing potassium bromide and oxalate ion is purified and analyzed. It contains 10.0% Mn, 28.6% potassium, 8.8% carbon, and 29.2% bromine by mass. The remainder of the compound is oxygen. An aqueous solution of the complex has about the same electrical conductivity as an equimolar solution of K₄[Fe(CN)₆]. Write the formula of the compound, using brackets to denote the manganese and its coordination sphere.

- 23.93** The *E*^o values for two low-spin iron complexes in acidic solution are as follows:

(a) Is it thermodynamically favorable to reduce both Fe(III) complexes to their Fe(II) analogs? Explain. (b) Which complex, [Fe(*o*-phen)₃]³⁺ or [Fe(CN)₆]³⁻, is more difficult to reduce? (c) Suggest an explanation for your answer to (b).

- 23.94** A palladium complex formed from a solution containing bromide ion and pyridine, C₅H₅N (a good electron-pair donor), is found on elemental analysis to contain 37.6% bromine, 28.3% carbon, 6.60% nitrogen, and 2.37% hydrogen by mass. The compound is slightly soluble in several organic solvents; its solutions in water or alcohol do not conduct electricity. It is found experimentally to have a zero dipole moment. Write the chemical formula, and indicate its probable structure.

- 23.95** (a) In early studies it was observed that when the complex [Co(NH₃)₄Br₂]Br was placed in water, the electrical conductivity of a 0.05 *M* solution changed from an initial value of 191 ohm⁻¹ to a final value of 374 ohm⁻¹ over a period of an hour or so. Suggest an explanation for the observed results. (See Exercise 23.67 for relevant comparison data.) (b) Write a balanced chemical equation to describe the reaction. (c) A 500-mL solution is made up by dissolving 3.87 g of the complex. As soon

as the solution is formed, and before any change in conductivity has occurred, a 25.00-mL portion of the solution is titrated with 0.0100 M AgNO₃ solution. What volume of AgNO₃ solution do you expect to be required to precipitate the free Br⁻(aq)? (d) Based on the response you gave to part (b), what volume of AgNO₃ solution would be required to titrate a fresh 25.00-mL sample of [Co(NH₃)₄Br₂]Br after all conductivity changes have occurred?

- 23.96** The total concentration of Ca²⁺ and Mg²⁺ in a sample of hard water was determined by titrating a 0.100-L sample of the water with a solution of EDTA⁴⁻. The EDTA⁴⁻ chelates the two cations:

It requires 31.5 mL of 0.0104 M [EDTA]⁴⁻ solution to reach the end point in the titration. A second 0.100-L sample was then treated with sulfate ion to precipitate Ca²⁺ as calcium sulfate. The Mg²⁺ was then titrated with 18.7 mL of 0.0104 M [EDTA]⁴⁻. Calculate the concentrations of Mg²⁺ and Ca²⁺ in the hard water in mg/L.

- 23.97** Carbon monoxide is toxic because it binds more strongly to the iron in hemoglobin (Hb) than does O₂, as indicated by these approximate standard free-energy changes in blood:

Using these data, estimate the equilibrium constant at 298 K for the equilibrium

- [23.98]** The molecule *methylamine* (CH₃NH₂) can act as a monodentate ligand. The following are equilibrium reactions and the thermochemical data at 298 K for reactions of methylamine and en with Cd²⁺(aq):

$$\Delta H^\circ = -57.3 \text{ kJ}; \quad \Delta S^\circ = -67.3 \text{ J/K}; \quad \Delta G^\circ = -37.2 \text{ kJ}$$

$$\Delta H^\circ = -56.5 \text{ kJ}; \quad \Delta S^\circ = +14.1 \text{ J/K}; \quad \Delta G^\circ = -60.7 \text{ kJ}$$

(a) Calculate ΔG° and the equilibrium constant K for the following *ligand exchange* reaction:

Based on the value of K in part (a), what would you conclude about this reaction? What concept is demonstrated? (b) Determine the magnitudes of the enthalpic (ΔH°) and the entropic ($-T\Delta S^\circ$) contributions to ΔG° for the ligand exchange reaction. Explain the relative magnitudes. (c) Based on information in this exercise and in the "A Closer Look" box on the chelate effect, predict the sign of ΔH° for the following hypothetical reaction:

- 23.99** The value of Δ for the [CrF₆]³⁻ complex is 182 kJ/mol. Calculate the expected wavelength of the absorption corresponding to promotion of an electron from the lower-energy to the higher-energy *d*-orbital set in this complex. Should the complex absorb in the visible range?

- [23.100]** A Cu electrode is immersed in a solution that is 1.00 M in [Cu(NH₃)₄]²⁺ and 1.00 M in NH₃. When the cathode is a standard hydrogen electrode, the emf of the cell is found to be +0.08 V. What is the formation constant for [Cu(NH₃)₄]²⁺?

- [23.101]** The complex [Ru(EDTA)(H₂O)]⁻ undergoes substitution reactions with several ligands, replacing the water molecule with the ligand. In all cases the ruthenium stays in the +3 oxidation state and the ligands use a nitrogen donor atom to bind to the metal.

The rate constants for several ligands are as follows:

Ligand, L	k (M ⁻¹ s ⁻¹)
Pyridine	6.3×10^3
SCN ⁻	2.7×10^2
CH ₃ CN	3.0×10

(a) One possible mechanism for this substitution reaction is that the water molecule dissociates from the Ru(III) in the rate-determining step, and then the ligand L binds to Ru(III) in a rapid second step. A second possible mechanism is that L approaches the complex, begins to form a new bond to the Ru(III), and displaces the water molecule, all in a single concerted step. Which of these two mechanisms is more consistent with the data? Explain. (b) What do the results suggest about the relative donor ability of the nitrogens of the three ligands toward Ru(III)? (c) Assuming that the complexes are all low spin, how many unpaired electrons are in each?

WHAT'S AHEAD

24.1 GENERAL CHARACTERISTICS OF ORGANIC MOLECULES

We begin with a review of the structures and reactivities of organic compounds.

24.2 INTRODUCTION TO HYDROCARBONS

We consider *hydrocarbons*, compounds containing only C and H, including the hydrocarbons called *alkanes*, which contain only single bonds. We also look at *isomers*, compounds with identical compositions but different molecular structures.

24.3 ALKENES, ALKYNES, AND AROMATIC HYDROCARBONS

We next explore hydrocarbons with one or more C=C bonds, called *alkenes*, and those with one or more C≡C bonds, called

alkynes. *Aromatic* hydrocarbons have at least one planar ring with delocalized π electrons.

24.4 ORGANIC FUNCTIONAL GROUPS

We recognize that a central organizing principle of organic chemistry is the *functional group*, a group of atoms at which most of the compound's chemical reactions occur.

24.5 CHIRALITY IN ORGANIC CHEMISTRY

We learn that compounds with nonsuperimposable mirror images are *chiral* and that chirality plays important roles in organic and biological chemistry.

TO COMMUNICATE WITH OTHER members of their species, insects release chemicals called pheromones into their environment.

24.6 INTRODUCTION TO BIOCHEMISTRY

We introduce the chemistry of living organisms, known as *biochemistry*, *biological chemistry*, or *chemical biology*. Important classes of compounds that occur in living systems are *proteins*, *carbohydrates*, *lipids*, and *nucleic acids*.

24.7 PROTEINS

We learn that proteins are polymers of *amino acids* linked with *amide* (also called *peptide*) bonds. Proteins are used for structural support and as molecular transporters and enzymes.

24.8 CARBOHYDRATES

We observe that carbohydrates are sugars and polymers of sugars used primarily as fuel by organisms (glucose) or as structural support in plants (cellulose).

24.9 LIPIDS

We recognize that lipids are a large class of molecules used primarily for energy storage in organisms.

24.10 NUCLEIC ACIDS

We learn that nucleic acids are polymers of *nucleotides* that contain an organism's genetic information. *Deoxyribonucleic acid* (DNA) and *ribonucleic acid* (RNA) are polymers composed of nucleotides.

THE CHEMISTRY OF LIFE: ORGANIC AND BIOLOGICAL CHEMISTRY

INSECTS COMMUNICATE BY RELEASING substances called pheromones, which they detect with their antennae. There are sex, alarm, defense, and trail pheromones. For example, isoamyl acetate [3-methylbutyl acetate, $(\text{CH}_3)_2\text{CHCH}_2\text{COOCH}_3$] is an alarm pheromone for bees, attracting other bees and

provoking them to sting. Mammals, including humans, may also respond to pheromones, although the identity and function of pheromones in humans are not conclusive. Nevertheless, google "pheromone" and you will find hundreds of sources trying to sell you a pheromone, claiming that it will make you irresistible to the opposite sex.

Although biological systems are almost unimaginably complex, they are nevertheless constructed of molecules of quite modest size, as, for instance, the isoamyl acetate pheromone just described. To understand biology, therefore, we need to understand the chemical behaviors of molecules. This chapter is about the molecules, composed mainly of carbon, hydrogen, oxygen, and nitrogen, that form the basis of organic and biological chemistry.

More than 16 million carbon-containing compounds are known. Chemists make thousands of new compounds every year, about 90% of which contain carbon. The study of compounds whose molecules contain carbon constitutes the branch of chemistry known as **organic chemistry**. This term arose from the eighteenth-century belief that organic compounds could be formed only by living (that is, organic) systems. This idea was disproved in 1828 by the German chemist Friedrich Wöhler when he synthesized urea (H_2NCONH_2), an organic substance found in the urine of mammals, by heating ammonium cyanate (NH_4OCN), an inorganic (“nonliving”) substance.

The study of the chemistry of living species is called *biological chemistry*, *chemical biology*, or **biochemistry**. In this chapter, we present some of the elementary aspects of both organic chemistry and biochemistry.

24.1 GENERAL CHARACTERISTICS OF ORGANIC MOLECULES

What is it about carbon that leads to the tremendous diversity in its compounds and allows it to play such crucial roles in biology and society? Let’s consider some general features of organic molecules and, as we do, review principles we learned in earlier chapters.

The Structures of Organic Molecules

Because carbon has four valence electrons ($[\text{He}]2s^22p^2$), it forms four bonds in virtually all its compounds. When all four bonds are single bonds, the electron pairs are disposed in a tetrahedral arrangement. ∞ (Section 9.2) In the hybridization model, the carbon $2s$ and $2p$ orbitals are then sp^3 hybridized. ∞ (Section 9.5) When there is one double bond, the arrangement is trigonal planar (sp^2 hybridization). With a triple bond, it is linear (sp hybridization). Examples are shown in \blacktriangledown **FIGURE 24.1**.

Almost every organic molecule contains C—H bonds. Because the valence shell of H can hold only two electrons, hydrogen forms only one covalent bond. As a result,

GO FIGURE

What is the geometry around the bottom carbon atom in acetonitrile?

► FIGURE 24.1 Carbon geometries. The three common geometries around carbon are tetrahedral as in methane (CH_4), trigonal planar as in formaldehyde (CH_2O), and linear as in acetonitrile (CH_3CN). Notice that in all cases each carbon atom forms four bonds.

hydrogen atoms are always located on the *surface* of organic molecules whereas the C—C bonds form the *backbone*, or *skeleton*, of the molecule, as in the propane molecule:

The Stabilities of Organic Substances

Carbon forms strong bonds with a variety of elements, especially H, O, N, and the halogens. ∞ (Section 8.8) Carbon also has an exceptional ability to bond to itself, forming a variety of molecules made up of chains or rings of carbon atoms. Most reactions with low or moderate activation energy (Section 14.5) begin when a region of high electron density on one molecule encounters a region of low electron density on another molecule. The regions of high electron density may be due to the presence of a multiple bond or to the more electronegative atom in a polar bond. Because of their strength and lack of polarity, both C—C single bonds and C—H bonds are relatively unreactive. To better understand the implications of these facts, consider ethanol:

The differences in the electronegativity values of C (2.5) and O (3.5) and of O and H (2.1) indicate that the C—O and O—H bonds are quite polar. Thus, many reactions of ethanol involve these bonds while the hydrocarbon portion of the molecule remains intact. A group of atoms such as the C—O—H group, which determines how an organic molecule reacts (in other words, how the molecule *functions*), is called a **functional group**. The functional group is the center of reactivity in an organic molecule.

GIVE IT SOME THOUGHT

Which bond is most likely to be the location of a chemical reaction: C=N, C—C, or C—H?

Solubility and Acid–Base Properties of Organic Substances

In most organic substances, the most prevalent bonds are carbon–carbon and carbon–hydrogen, which have low polarity. For this reason, the overall polarity of organic molecules is often low, which makes them generally soluble in nonpolar solvents and not very soluble in water. ∞ (Section 13.3) Organic molecules that are soluble in polar solvents are those that have polar groups on the molecule surface, such as glucose and ascorbic acid (► FIGURE 24.2). Organic molecules that have a long, nonpolar part bonded to a polar, ionic part, such as the stearate ion shown in Figure 24.2, function as *surfactants* and are used in soaps and detergents. ∞ (Section 13.6) The nonpolar part of the molecule extends into a nonpolar medium such as grease or oil, and the polar part extends into a polar medium such as water.

Many organic substances contain acidic or basic groups. The most important acidic organic substances are the carboxylic acids, which bear the functional group —COOH. ∞ (Sections 4.3 and 16.10) The most important basic organic substances are amines, which bear the —NH₂, —NHR, or —NR₂ groups, where R is an organic group made up of carbon and hydrogen atoms. ∞ (Section 16.7)

As you read this chapter, you will find many concept links (∞) to related materials in earlier chapters. *We strongly encourage you to follow these links and review the earlier material.* Doing so will enhance your understanding and appreciation of organic chemistry and biochemistry.

24.2 INTRODUCTION TO HYDROCARBONS

Because carbon compounds are so numerous, it is convenient to organize them into families that have structural similarities. The simplest class of organic compounds is the *hydrocarbons*, compounds composed of only carbon and hydrogen. The key structural feature of hydrocarbons (and of most other organic substances) is the presence of stable carbon–carbon bonds. Carbon is the only element capable of forming stable, extended chains of atoms bonded through single, double, or triple bonds.

Hydrocarbons can be divided into four types, depending on the kinds of carbon–carbon bonds in their molecules. ▼ **TABLE 24.1** shows an example of each type.

Alkanes contain only single bonds. **Alkenes**, also known as *olefins*, contain at least one C=C double bond, and **alkynes** contain at least one C≡C triple bond. In **aromatic hydrocarbons** the carbon atoms are connected in a planar ring structure, joined by both σ and delocalized π bonds between carbon atoms. Benzene (C₆H₆) is the best-known example of an aromatic hydrocarbon.

Each type of hydrocarbon exhibits different chemical behaviors, as we will see shortly. The physical properties of all four types, however, are similar in many ways. Because hydrocarbon molecules are relatively nonpolar, they are almost completely insoluble in water but dissolve readily in nonpolar solvents. Their melting points and boiling points are determined by dispersion forces. ∞ (Section 11.2) As a result, hydrocarbons of very low molecular weight, such as C₂H₆ (bp = −89 °C), are gases at room temperature; those of moderate molecular weight, such as C₆H₁₄ (bp = 69 °C), are liquids; and those of high molecular weight, such as C₂₂H₄₆ (mp = 44 °C), are solids.

► **TABLE 24.2** lists the ten simplest alkanes. Many of these substances are familiar because they are used so widely. Methane is a major component of natural gas and is used for home heating and in gas stoves and water heaters. Propane is the major component of bottled gas used for home heating and cooking in areas where natural gas is not available. Butane is used in disposable lighters and in fuel canisters for gas camping stoves and lanterns. Alkanes with from 5 to 12 carbon atoms per molecule are used to make gasoline. Notice that each succeeding compound in Table 24.2 has an additional CH₂ unit.

TABLE 24.1 • The Four Hydrocarbon Types

Type	Example		
Alkane	Ethane	CH ₃ CH ₃	 
Alkene	Ethylene	CH ₂ =CH ₂	 
Alkyne	Acetylene	CH≡CH	 
Aromatic	Benzene	C ₆ H ₆	 

TABLE 24.2 • First Ten Members of the Straight-Chain Alkane Series

Molecular Formula	Condensed Structural Formula	Name	Boiling Point (°C)
CH ₄	CH ₄	Methane	-161
C ₂ H ₆	CH ₃ CH ₃	Ethane	-89
C ₃ H ₈	CH ₃ CH ₂ CH ₃	Propane	-44
C ₄ H ₁₀	CH ₃ CH ₂ CH ₂ CH ₃	Butane	-0.5
C ₅ H ₁₂	CH ₃ CH ₂ CH ₂ CH ₂ CH ₃	Pentane	36
C ₆ H ₁₄	CH ₃ CH ₂ CH ₂ CH ₂ CH ₂ CH ₃	Hexane	68
C ₇ H ₁₆	CH ₃ CH ₂ CH ₂ CH ₂ CH ₂ CH ₂ CH ₃	Heptane	98
C ₈ H ₁₈	CH ₃ CH ₂ CH ₂ CH ₂ CH ₂ CH ₂ CH ₂ CH ₃	Octane	125
C ₉ H ₂₀	CH ₃ CH ₂ CH ₂ CH ₂ CH ₂ CH ₂ CH ₂ CH ₂ CH ₃	Nonane	151
C ₁₀ H ₂₂	CH ₃ CH ₂ CH ₂ CH ₂ CH ₂ CH ₂ CH ₂ CH ₂ CH ₂ CH ₃	Decane	174

The formulas for the alkanes given in Table 24.2 are written in a notation called *condensed structural formulas*. This notation reveals the way in which atoms are bonded to one another but does not require drawing in all the bonds. For example, the structural formula and the condensed structural formulas for butane (C₄H₁₀) are

▲ GIVE IT SOME THOUGHT

How many C—H and C—C bonds are formed by the middle carbon atom of propane?

Structures of Alkanes

According to the VSEPR model, the molecular geometry about each carbon atom in an alkane is tetrahedral. ∞ (Section 9.2) The bonding may be described as involving *sp*³-hybridized orbitals on the carbon, as pictured in ► FIGURE 24.3 for methane. ∞ (Section 9.5)

Rotation about a carbon–carbon single bond is relatively easy and occurs rapidly at room temperature. To visualize such rotation, imagine grasping either methyl group of the propane molecule in ► FIGURE 24.4 and rotating the group relative to the rest of the molecule. Because motion of this sort occurs rapidly in alkanes, a long-chain alkane molecule is constantly undergoing motions that cause it to change its shape, something like a length of chain that is being shaken.

Structural Isomers

The alkanes in Table 24.2 are called *straight-chain hydrocarbons* because all the carbon atoms are joined in a continuous chain. Alkanes consisting of four or more carbon atoms can also form *branched chains*, and when they do, they are called *branched-chain hydrocarbons*. (The branches in organic molecules are often called *side chains*.) ► TABLE 24.3, for example, shows all the straight-chain and branched-chain alkanes containing four and five carbon atoms.

Compounds that have the same molecular formula but different bonding arrangements (and hence different structures) are called **structural isomers**. Thus, C₄H₁₀ has two structural isomers and C₅H₁₂ has three. The structural isomers of a given alkane differ slightly from one another in physical properties, as the melting and boiling points in Table 24.3 indicate.

The number of possible structural isomers increases rapidly with the number of carbon atoms in the alkane. There are 18 isomers with the molecular formula C₈H₁₈, for example, and 75 with the molecular formula C₁₀H₂₂.

▲ FIGURE 24.3 Bonds about carbon in methane. This tetrahedral molecular geometry is found around all carbons in alkanes.

▲ FIGURE 24.4 Rotation about a C—C bond occurs easily and rapidly in all alkanes.

TABLE 24.3 • Isomers of C₄H₁₀ and C₅H₁₂

GIVE IT SOME THOUGHT

What evidence can you cite to support the fact that although isomers have the same molecular formula they are in fact different compounds?

Nomenclature of Alkanes

In the first column of Table 24.3, the names in parentheses are called the *common names*. The common name of the isomer with no branches begins with the letter *n* (indicating the “normal” structure). When one CH₃ group branches off the major chain, the common name of the isomer begins with *iso-*, and when two CH₃ groups branch off, the common name begins with *neo-*. As the number of isomers grows, however, it becomes impossible to find a suitable prefix to denote each isomer by a common name. The need for a systematic means of naming organic compounds was recognized as early as 1892, when an organization called the International Union of Chemistry met in Geneva to formulate rules for naming organic substances. Since that time the task of updating the

rules for naming compounds has fallen to the International Union of Pure and Applied Chemistry (IUPAC). Chemists everywhere, regardless of their nationality, subscribe to a common system for naming compounds.

The IUPAC names for the isomers of butane and pentane are the ones given first in Table 24.3. These systematic names, as well as those of other organic compounds, have three parts to them:

The following steps summarize the procedures used to name alkanes, which all have names ending with *-ane*. We use a similar approach to write the names of other organic compounds.

1. Find the longest continuous chain of carbon atoms, and use the name of this chain (given in Table 24.2) as the base name. Be careful in this step because the longest chain may not be written in a straight line, as in the following structure:

Because the longest continuous chain contains six C atoms, this isomer is named as a substituted hexane. Groups attached to the main chain are called *substituents* because they are substituted in place of an H atom on the main chain. In this molecule the CH_3 group not enclosed by the blue outline is the only substituent in the molecule.

2. Number the carbon atoms in the longest chain, beginning with the end nearest a substituent. In our example, we number the C atoms beginning at the upper right because that places the CH_3 substituent on C2 of the chain. (If we had numbered from the lower right, the CH_3 would be on C5.) The chain is numbered from the end that gives the lower number to the substituent position.
3. Name each substituent. A substituent formed by removing an H atom from an alkane is called an **alkyl group**. Alkyl groups are named by replacing the *-ane* ending of the alkane name with *-yl*. The methyl group (CH_3), for example, is derived from methane (CH_4) and the ethyl group (C_2H_5) is derived from ethane (C_2H_6). ► TABLE 24.4 lists six common alkyl groups.
4. Begin the name with the number or numbers of the carbon or carbons to which each substituent is bonded. For our compound, the name 2-methylhexane indicates the presence of a methyl group on C2 of a hexane (six-carbon) chain.
5. When two or more substituents are present, list them in alphabetical order. The presence of two or more of the same substituent is indicated by the prefixes *di-* (two), *tri-* (three), *tetra-* (four), *penta-* (five), and so forth. The prefixes are ignored in determining the alphabetical order of the substituents:

TABLE 24.4 • Condensed Structural Formulas and Common Names for Several Alkyl Groups

Group	Name

$\begin{array}{c} \text{CH}_3 \\ \\ \text{CH}_3—\text{C}— \\ \\ \text{CH}_3 \end{array}$	<i>tert</i> -Butyl

SAMPLE EXERCISE 24.1 Naming Alkanes

Give the systematic name for the following alkane:

**SOLUTION**

Analyze We are given the condensed structural formula of an alkane and asked to give its name.

Plan Because the hydrocarbon is an alkane, its name ends in *-ane*. The name of the parent hydrocarbon is based on the longest continuous chain of carbon atoms. Branches are alkyl groups, named after the number of C atoms in the branch and located by counting C atoms along the longest continuous chain.

Solve The longest continuous chain of C atoms extends from the upper left CH₃ group to the lower left CH₃ group and is seven C atoms long:

The parent compound is thus heptane. There are two methyl groups branching off the main chain. Hence, this compound is a dimethylheptane. To specify the location of the two methyl groups, we must number the C atoms from the end that gives the lower two numbers to the carbons bearing side chains. This means that we should start numbering at the upper left carbon. There is a methyl group on C3 and one on C4. The compound is thus 3,4-dimethylheptane.

PRACTICE EXERCISE

Name the following alkane:

Answer: 2,4-dimethylpentane

SAMPLE EXERCISE 24.2 Writing Condensed Structural Formulas

Write the condensed structural formula for 3-ethyl-2-methylpentane.

SOLUTION

Analyze We are given the systematic name for a hydrocarbon and asked to write its condensed structural formula.

Plan Because the name ends in *-ane*, the compound is an alkane, meaning that all the carbon-carbon bonds are single bonds. The parent hydrocarbon is pentane, indicating five C atoms (Table 24.2). There are two alkyl groups specified, an ethyl group (two carbon atoms, C₂H₅) and a methyl group (one carbon atom, CH₃). Counting from left to right along the five-carbon chain, the name tells us that the ethyl group is attached to C3 and the methyl group is attached to C2.

Solve We begin by writing five C atoms attached by single bonds. These represent the backbone of the parent pentane chain:

We next place a methyl group on the second C and an ethyl group on the third C of the chain. We then add hydrogens to all the other C atoms to make four bonds to each carbon:

The formula can be written more concisely as

where the branching alkyl groups are indicated in parentheses.

PRACTICE EXERCISE

Write the condensed structural formula for 2,3-dimethylhexane.

Cycloalkanes

Alkanes that form rings, or cycles, are called **cycloalkanes**. As **▼ FIGURE 24.5** illustrates, cycloalkane structures are sometimes drawn as *line structures*, which are polygons in which each corner represents a CH_2 group. This method of representation is similar to that used for benzene rings. ∞ (Section 8.6) (Remember from our benzene discussion that in aromatic structures each vertex represents a CH group, not a CH_2 group.)

Carbon rings containing fewer than five carbon atoms are strained because the $\text{C}-\text{C}-\text{C}$ bond angles must be less than the 109.5° tetrahedral angle. The amount of strain increases as the rings get smaller. In cyclopropane, which has the shape of an equilateral triangle, the angle is only 60° ; this molecule is therefore much more reactive than propane, its straight-chain analog.

Reactions of Alkanes

Because they contain only $\text{C}-\text{C}$ and $\text{C}-\text{H}$ bonds, most alkanes are relatively unreactive. At room temperature, for example, they do not react with acids, bases, or strong oxidizing agents. Their low chemical reactivity, as noted in Section 24.1, is due primarily to the strength and lack of polarity of $\text{C}-\text{C}$ and $\text{C}-\text{H}$ bonds.

Alkanes are not completely inert, however. One of their most commercially important reactions is *combustion* in air, which is the basis of their use as fuels. ∞ (Section 3.2) For example, the complete combustion of ethane proceeds as follows:

GO FIGURE

The general formula for straight-chain alkanes is $\text{C}_n\text{H}_{2n+2}$. What is the general formula for cycloalkanes?

▲ FIGURE 24.5 Condensed structural formulas and line structures for three cycloalkanes.

CHEMISTRY PUT TO WORK

Gasoline

Petroleum, or crude oil, is a mixture of hydrocarbons plus smaller quantities of other organic compounds containing nitrogen, oxygen, or sulfur. The tremendous demand for petroleum to meet the world's energy needs has led to the tapping of oil wells in such forbidding places as the North Sea and northern Alaska.

The usual first step in the *refining*, or processing, of petroleum is to separate it into fractions on the basis of boiling point (▼ TABLE 24.5). Because gasoline is the most commercially important of these fractions, various processes are used to maximize its yield.

Gasoline is a mixture of volatile alkanes and aromatic hydrocarbons. In a traditional automobile engine, a mixture of air and gasoline vapor is compressed by a piston and then ignited by a spark plug. The burning of the gasoline should create a strong, smooth expansion of gas, forcing the piston outward and imparting force along the driveshaft of the engine. If the gas burns too rapidly, the piston receives a single hard slam rather than a strong, smooth push. The result is a “knocking” or “pinging” sound and a reduction in the efficiency with which energy produced by the combustion is converted to work.

The *octane number* of a gasoline is a measure of its resistance to knocking. Gasolines with high octane numbers burn more smoothly and are thus more effective fuels (► FIGURE 24.6). Branched alkanes and aromatic hydrocarbons have higher octane numbers than straight-chain alkanes. The octane number of gasoline is obtained by comparing its knocking characteristics with those of isooctane (2,2,4-trimethylpentane) and heptane. Isooctane is assigned an octane number of 100, and heptane is assigned 0. Gasoline with the same knocking characteristics as a mixture of 91% isooctane and 9% heptane, for instance, is rated as 91 octane.

TABLE 24.5 • Hydrocarbon Fractions from Petroleum

Fraction	Size Range of Molecules	Boiling-Point Range (°C)	Uses
Gas	C ₁ to C ₅	−160 to 30	Gaseous fuel, production of H ₂
Straight-run gasoline	C ₅ to C ₁₂	30 to 200	Motor fuel
Kerosene, fuel oil	C ₁₂ to C ₁₈	180 to 400	Diesel fuel, furnace fuel, cracking
Lubricants	C ₁₆ and up	350 and up	Lubricants
Paraffins	C ₂₀ and up	Low-melting solids	Candles, matches
Asphalt	C ₃₆ and up	Gummy residues	Surfacing roads

▲ FIGURE 24.6 Octane rating. The octane rating of gasoline measures its resistance to knocking when burned in an engine. The octane rating of the gasoline in the foreground is 89.

The gasoline obtained by fractionating petroleum (called *straight-run* gasoline) contains mainly straight-chain hydrocarbons and has an octane number around 50. To increase its octane rating, it is subjected to a process called *reforming*, which converts the straight-chain alkanes into branched-chain ones.

Cracking is used to produce aromatic hydrocarbons and to convert some of the less-volatile fractions of petroleum into compounds suitable for use as automobile fuel. In cracking, the hydrocarbons are mixed with a catalyst and heated to 400 °C to 500 °C. The catalysts used are either clay minerals or synthetic Al₂O₃–SiO₂ mixtures. In addition to forming molecules more suitable for gasoline, cracking results in the formation of such low-molecular-weight hydrocarbons as ethylene and propene. These substances are used in a variety of reactions to form plastics and other chemicals.

Adding compounds called either *antiknock agents* or octane enhancers increases the octane rating of gasoline. Until the mid-1970s the principal antiknock agent was tetraethyl lead, (C₂H₅)₄Pb. It is no longer used, however, because of the environmental hazards of lead and because it poisons catalytic converters. ∞ (Section 14.7 “Chemistry Put to Work: Catalytic Converters”) Aromatic compounds such as toluene (C₆H₅CH₃) and oxygenated hydrocarbons such as ethanol (CH₃CH₂OH) are now generally used as antiknock agents.

RELATED EXERCISES: 24.19 and 24.20

24.3 ALKENES, ALKYNES, AND AROMATIC HYDROCARBONS

Because alkanes have only single bonds, they contain the largest possible number of hydrogen atoms per carbon atom. As a result, they are called *saturated hydrocarbons*. Alkenes, alkynes, and aromatic hydrocarbons contain multiple bonds (double, triple, or delocalized π bonds). As a result, they contain less hydrogen than an alkane with the

GO FIGURE

How many isomers are there for propene, C_3H_6 ?

▲ FIGURE 24.7 The alkene C_4H_8 has four structural isomers.

same number of carbon atoms. Collectively, they are called *unsaturated hydrocarbons*. On the whole, unsaturated molecules are more reactive than saturated ones.

Alkenes

Alkenes are unsaturated hydrocarbons that contain at least one $C=C$ bond. The simplest alkene is $CH_2=CH_2$, called ethene (IUPAC) or ethylene, which plays important roles as a plant hormone in seed germination and fruit ripening. The next member of the series is $CH_3-CH=CH_2$, called propene or propylene. Alkenes with four or more carbon atoms have several isomers. For example, the alkene C_4H_8 has the four structural isomers shown in ▲ FIGURE 24.7. Notice both their structures and their names.

The names of alkenes are based on the longest continuous chain of carbon atoms that contains the double bond. The chain is named by changing the ending of the name of the corresponding alkane from *-ane* to *-ene*. The compound on the left in Figure 24.7, for example, has a double bond as part of a three-carbon chain; thus, the parent alkene is propene.

The location of the double bond along an alkene chain is indicated by a prefix number that designates the double-bond carbon atom that is nearest an end of the chain. The chain is always numbered from the end that brings us to the double bond sooner and hence gives the smallest-numbered prefix. In propene the only possible location for the double bond is between the first and second carbons; thus, a prefix indicating its location is unnecessary. For butene (Figure 24.7) there are two possible positions for the double bond, either after the first carbon (1-butene) or after the second carbon (2-butene).

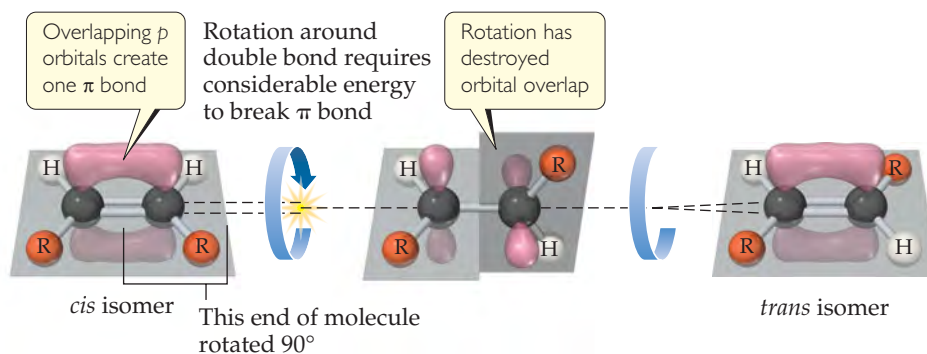

GIVE IT SOME THOUGHT

How many distinct locations are there for a double bond in a five-carbon linear chain?

If a substance contains two or more double bonds, the location of each is indicated by a numerical prefix, and the ending of the name is altered to identify the number of double bonds: diene (two), triene (three), and so forth. For example, $CH_2=CH-CH_2-CH=CH_2$ is 1,4-pentadiene.

The two isomers on the right in Figure 24.7 differ in the relative locations of their methyl groups. These two compounds are **geometric isomers**, compounds that have the same molecular formula and the same groups bonded to one another but differ in the spatial arrangement of these groups. ∞ (Section 23.4) In the *cis* isomer the two methyl groups are on the same side of the double bond, whereas in the *trans* isomer they are on opposite sides. Geometric isomers possess distinct physical properties and can differ significantly from each other in their chemical behavior.

► **FIGURE 24.8** Geometric isomers exist because rotation about a carbon–carbon double bond requires too much energy to occur at ordinary temperatures.

Geometric isomerism in alkenes arises because, unlike the C—C bond, the C=C bond resists twisting. Recall from Section 9.6 that the double bond between two carbon atoms consists of a σ and a π bond. ▲ **FIGURE 24.8** shows a *cis* alkene. The carbon–carbon bond axis and the bonds to the hydrogen atoms and to the alkyl groups (designated R) are all in a plane, and the *p* orbitals that form the π bond are perpendicular to that plane. As Figure 24.8 shows, rotation around the carbon–carbon double bond requires the π bond to be broken, a process that requires considerable energy (about 250 kJ/mol). Because rotation doesn't occur easily around the carbon–carbon bond, the *cis* and *trans* isomers of an alkene cannot readily interconvert and, therefore, exist as distinct compounds.

SAMPLE EXERCISE 24.3 Drawing Isomers

Draw all the structural and geometric isomers of pentene, C_5H_{10} , that have an unbranched hydrocarbon chain.

SOLUTION

Analyze We are asked to draw all the isomers (both structural and geometric) for an alkene with a five-carbon chain.

Plan Because the compound is named pentene and not pentadiene or pentatriene, we know that the five-carbon chain contains only one carbon–carbon double bond. Thus, we begin by placing the double bond in various locations along the chain, remembering that the chain can be numbered from either end. After finding the different unique locations for the double bond, we consider whether the molecule can have *cis* and *trans* isomers.

Solve There can be a double bond after either the first carbon (1-pentene) or second carbon (2-pentene). These are the only two possibilities because the chain can be numbered from either end. Thus, what we might erroneously call 3-pentene is actually 2-pentene, as seen by numbering the carbon chain from the other end:

Because the first C atom in 1-pentene is bonded to two H atoms, there are no *cis*-*trans* isomers. There are *cis* and *trans* isomers for 2-pentene, however. Thus, the three isomers for pentene are

The pair of electrons that forms the π bond in ethylene is uncoupled and is used to form two σ bonds to the two bromine atoms. The σ bond between the carbon atoms is retained.

Addition of H_2 to an alkene converts it to an alkane:

The reaction between an alkene and H_2 , referred to as *hydrogenation*, does not occur readily at ordinary temperatures and pressures. One reason for the lack of reactivity of H_2 toward alkenes is the stability of the $H-H$ bond. To promote the reaction, a catalyst is used to assist in rupturing the $H-H$ bond. The most widely used catalysts are finely divided metals on which H_2 is adsorbed. ∞ (Section 14.7)

Hydrogen halides and water can also add to the double bond of alkenes, as in these reactions of ethylene:

The addition of water is catalyzed by a strong acid, such as H_2SO_4 .

The addition reactions of alkynes resemble those of alkenes, as shown in these examples:

SAMPLE EXERCISE 24.5 Identifying the Product of a Hydrogenation Reaction

Write the condensed structural formula for the product of the hydrogenation of 3-methyl-1-pentene.

SOLUTION

Analyze We are asked to predict the compound formed when a particular alkene undergoes hydrogenation (reaction with H_2) and to write the condensed structural formula of the product.

Plan To determine the condensed structural formula of the product, we must first write the condensed structural formula or Lewis structure of the reactant. In the hydrogenation of the alkene, H_2 adds to the double bond, producing an alkane.

Solve The name of the starting compound tells us that we have a chain of five C atoms with a double bond at one end (position 1) and a methyl group on C3:

Hydrogenation—the addition of two H atoms to the carbons of the double bond—leads to the following alkane:

Comment The longest chain in this alkane has five carbon atoms; the product is therefore 3-methylpentane.

PRACTICE EXERCISE

Addition of HCl to an alkene forms 2-chloropropane. What is the alkene?

Answer: propene

A CLOSER LOOK

MECHANISM OF ADDITION REACTIONS

As the understanding of chemistry has grown, chemists have advanced from simply cataloging reactions known to occur to explaining *how* they occur. An explanation of how a reaction occurs is called a *mechanism*. ∞ (Section 14.6)

The addition reaction between HBr and an alkene, for instance, is thought to proceed in two steps. In the first step, which is rate determining ∞ (Section 14.6), the HBr attacks the electron-rich double bond, transferring a proton to one of the double-bond carbons. In the reaction of 2-butene with HBr, for example, the first step is

The electron pair that formed the π bond is used to form the new C—H bond.

The second, faster step is addition of Br^- to the positively charged carbon. The bromide ion donates a pair of electrons to the carbon, forming the C—Br bond:

Because the rate-determining step involves both the alkene and the acid, the rate law for the reaction is second order, first order in the alkene and first order in HBr:

$$\text{Rate} = -\frac{\Delta[\text{CH}_3\text{CH}=\text{CHCH}_3]}{\Delta t} = k[\text{CH}_3\text{CH}=\text{CHCH}_3][\text{HBr}] \quad [24.9]$$

The energy profile for the reaction is shown in ▼ FIGURE 24.9. The first energy maximum represents the transition state in the first step, and the second maximum represents the transition state in the second step. The energy minimum represents the energies of the intermediate species, $\text{CH}_3\overset{+}{\text{C}}\text{H}-\text{CH}_2\text{CH}_3$ and Br^- .

To show electron movement in reactions like these, chemists often use curved arrows pointing in the direction of electron flow. For the addition of HBr to 2-butene, for example, the shifts in electron positions are shown as

GO FIGURE

What features of an energy profile allow you to distinguish between an intermediate and a transition state?

▲ FIGURE 24.9 Energy profile for addition of HBr to 2-butene. The two maxima tell you that this is a two-step mechanism.

Aromatic Hydrocarbons

The simplest aromatic hydrocarbon, benzene (C_6H_6), is shown in ▼ FIGURE 24.10 along with some other aromatic hydrocarbons. Benzene is the most important aromatic hydrocarbon, and most of our discussion focuses on it.

◀ FIGURE 24.10 Line formulas and common names of several aromatic compounds. The aromatic rings are represented by hexagons with a circle inscribed inside to denote delocalized π bonds. Each corner represents a carbon atom. Each carbon is bound to three other atoms—either three carbons or two carbons and a hydrogen—so that each carbon has the requisite four bonds.

Stabilization of π Electrons by Delocalization

The planar structure of benzene, with its 120° bond angles, suggests a high degree of unsaturation. You might therefore expect benzene to resemble the alkenes and to be highly reactive. Benzene and the other aromatic hydrocarbons, however, are much more stable than alkenes because the π electrons are delocalized in the π orbitals. ∞ (Section 9.6)

We can estimate the stabilization of the π electrons in benzene by comparing the energy required to form cyclohexane by adding hydrogen to benzene, to cyclohexene (one double bond) and to 1,4-cyclohexadiene (two double bonds):

From the second and third reactions, it appears that the energy required to hydrogenate each double bond is roughly 118 kJ/mol for each bond. Benzene contains the equivalent of three double bonds. We might expect, therefore, the energy required to hydrogenate benzene to be about 3 times -118 , or -354 kJ/mol, if benzene behaved as though it were “cyclohexatriene,” that is, if it behaved as though it had three isolated double bonds in a ring. Instead, the energy released is 146 kJ less than this, indicating that benzene is more stable than would be expected for three double bonds. The difference of 146 kJ/mol between the “expected” heat (that is, enthalpy) of hydrogenation, -354 kJ/mol, and the observed heat of hydrogenation, -208 kJ/mol, is due to stabilization of the π electrons through delocalization in the π orbitals that extend around the ring.

Substitution Reactions

Although aromatic hydrocarbons are unsaturated, *they do not readily undergo addition reactions*. The delocalized π bonding causes aromatic compounds to behave quite differently from alkenes and alkynes. Benzene, for example, does not add Cl_2 or Br_2 to its double bonds under ordinary conditions. In contrast, aromatic hydrocarbons undergo **substitution reactions** relatively easily. In a substitution reaction one hydrogen atom of a molecule is removed and replaced (substituted) by another atom or group of atoms. When benzene is warmed in a mixture of nitric and sulfuric acids, for example, one of the benzene hydrogens is replaced by the nitro group, NO_2 :

More vigorous treatment results in substitution of a second nitro group into the molecule:

There are three isomers of benzene that contain two nitro groups—*ortho*-, *meta*-, and *para*-dinitrobenzene:

In the reaction of Equation 24.11, the principal product is the *meta* isomer.

Bromination of benzene, carried out with FeBr_3 as a catalyst, is another substitution reaction:

In a similar reaction, called the *Friedel-Crafts reaction*, alkyl groups can be substituted onto an aromatic ring by reacting an alkyl halide with an aromatic compound in the presence of AlCl_3 as a catalyst:

GIVE IT SOME THOUGHT

When the aromatic hydrocarbon naphthalene, shown in Figure 24.10, reacts with nitric and sulfuric acids, two compounds containing one nitro group are formed. Draw the structures of these two compounds.

24.4 ORGANIC FUNCTIONAL GROUPS

The $\text{C}=\text{C}$ double bonds of alkenes and $\text{C}\equiv\text{C}$ triple bonds of alkynes are just two of many functional groups in organic molecules. As noted earlier, these functional groups each undergo characteristic reactions, and the same is true of all other functional groups. Each kind of functional group often undergoes the same kinds of reactions in every molecule, regardless of the size and complexity of the molecule. Thus, the chemistry of an organic molecule is largely determined by the functional groups it contains.

► **TABLE 24.6** lists the most common functional groups. Notice that, except for $\text{C}=\text{C}$ and $\text{C}\equiv\text{C}$, they all contain either O, N, or a halogen atom, X.

We can think of organic molecules as being composed of functional groups bonded to one or more alkyl groups. The alkyl groups, which are made of $\text{C}-\text{C}$ and $\text{C}-\text{H}$ single bonds, are the less reactive portions of the molecules. In describing general features of organic compounds, chemists often use the designation R to represent any alkyl group: methyl, ethyl, propyl, and so on. Alkanes, for example, which contain no functional group, are represented as $\text{R}-\text{H}$. Alcohols, which contain the group $-\text{OH}$, are represented as $\text{R}-\text{OH}$. If two or more different alkyl groups are present in a molecule, we designate them R, R', R'', and so forth.

TABLE 24.6 • Common Functional Groups

Functional Group	Compound Type	Suffix or Prefix	Example		
			Structural Formula	Ball-and-stick Model	Systematic Name (common name)
	Alkene	<i>-ene</i>			Ethene (Ethylene)
$\text{—C}\equiv\text{C—}$	Alkyne	<i>-yne</i>	$\text{H—C}\equiv\text{C—H}$		Ethyne (Acetylene)
	Alcohol	<i>-ol</i>			Methanol (Methyl alcohol)
	Ether	<i>ether</i>			Dimethyl ether
 (X = halogen)	Haloalkane	<i>halo-</i>			Chloromethane (Methyl chloride)
	Amine	<i>-amine</i>			Ethylamine
	Aldehyde	<i>-al</i>			Ethanal (Acetaldehyde)
	Ketone	<i>-one</i>			Propanone (Acetone)
	Carboxylic acid	<i>-oic acid</i>			Ethanoic acid (Acetic acid)
	Ester	<i>-oate</i>			Methyl ethanoate (Methyl acetate)
	Amide	<i>-amide</i>			Ethanamide (Acetamide)

◀ **FIGURE 24.11** Condensed structural formulas of six important alcohols. Common names are given in blue.

Alcohols

Alcohols are hydrocarbon derivatives in which one or more hydrogens of a parent hydrocarbon have been replaced by the functional group —OH, called either the *hydroxyl group* or the *alcohol group*. Note in ▲ **FIGURE 24.11** that the name for an alcohol ends in *-ol*. The simple alcohols are named by changing the last letter in the name of the corresponding alkane to *-ol*—for example, ethane becomes ethanol. Where necessary, the location of the OH group is designated by a numeric prefix that indicates the number of the carbon atom bearing the OH group.

The O—H bond is polar, so alcohols are much more soluble in polar solvents than are hydrocarbons. The —OH functional group can also participate in hydrogen bonding. As a result, the boiling points of alcohols are much higher than those of their parent alkanes.

► **FIGURE 24.12** shows several commercial products that consist entirely or in large part of an organic alcohol.

The simplest alcohol, methanol (methyl alcohol), has many industrial uses and is produced on a large scale by heating carbon monoxide and hydrogen under pressure in the presence of a metal oxide catalyst:

Because methanol has a very high octane rating as an automobile fuel, it is used as a gasoline additive and as a fuel in its own right.

Ethanol (ethyl alcohol, $\text{C}_2\text{H}_5\text{OH}$) is a product of the fermentation of carbohydrates such as sugars and starches. In the absence of air, yeast cells convert these carbohydrates into ethanol and CO_2 :

In the process, the yeast cells derive energy necessary for growth. This reaction is carried out under carefully controlled conditions to produce beer, wine, and other beverages in which ethanol is the active ingredient.

The simplest polyhydroxyl alcohol (an alcohol containing more than one OH group) is 1,2-ethanediol (ethylene glycol, $\text{HOCH}_2\text{CH}_2\text{OH}$), the major ingredient in automobile antifreeze. Another common polyhydroxyl alcohol is 1,2,3-propanetriol [glycerol, $\text{HOCH}_2\text{CH(OH)CH}_2\text{OH}$], a viscous liquid that dissolves readily in water and is used in cosmetics as a skin softener and in foods and candies to keep them moist.

Phenol is the simplest compound with an OH group attached to an aromatic ring. One of the most striking effects of the aromatic group is the greatly increased acidity of the OH group. Phenol is about 1 million times more acidic in water than a nonaromatic alcohol. Even so, it is not a very strong acid ($K_a = 1.3 \times 10^{-10}$). Phenol is used industrially to make plastics and dyes, and as a topical anesthetic in throat sprays.

▲ **FIGURE 24.12** Everyday alcohols. Many of the products we use every day—from rubbing alcohol to hair spray and antifreeze—are composed either entirely or mainly of alcohols.

Cholesterol, shown in Figure 24.11, is a biochemically important alcohol. The OH group forms only a small component of this molecule, so cholesterol is only slightly soluble in water (0.26 g per 100 mL of H₂O). Cholesterol is a normal component of our bodies; when present in excessive amounts, however, it may precipitate from solution. It precipitates in the gallbladder to form crystalline lumps called *gallstones*. It may also precipitate against the walls of veins and arteries and thus contribute to high blood pressure and other cardiovascular problems.

Ethers

Compounds in which two hydrocarbon groups are bonded to one oxygen are called **ethers**. Ethers can be formed from two molecules of alcohol by splitting out a molecule of water. The reaction is catalyzed by sulfuric acid, which takes up water to remove it from the system:

A reaction in which water is split out from two substances is called a *condensation reaction*. ∞ (Sections 12.8 and 22.8)

Both diethyl ether and the cyclic ether tetrahydrofuran are common solvents for organic reactions:

Aldehydes and Ketones

Several of the functional groups listed in Table 24.6 contain the **carbonyl group**, C=O. This group, together with the atoms attached to its carbon, defines several important functional groups that we consider in this section.

In **aldehydes** the carbonyl group has at least one hydrogen atom attached:

In **ketones** the carbonyl group occurs at the interior of a carbon chain and is therefore flanked by carbon atoms:

Notice that the systematic names of aldehydes contain *-al* and that ketone names contain *-one*.

Aldehydes and ketones can be prepared by controlled oxidation of alcohols. Complete oxidation results in formation of CO₂ and H₂O, as in the burning of methanol:

Controlled partial oxidation to form other organic substances, such as aldehydes and ketones, is carried out by using various oxidizing agents, such as air, hydrogen peroxide (H₂O₂), ozone (O₃), and potassium dichromate (K₂Cr₂O₇).

GIVE IT SOME THOUGHT

Write the condensed structural formula for the ketone that would result from partial oxidation of the alcohol

Many compounds found in nature contain an aldehyde or ketone functional group. Vanilla and cinnamon flavorings are naturally occurring aldehydes. Two isomers of the ketone carvone impart the characteristic flavors of spearmint leaves and caraway seeds.

Ketones are less reactive than aldehydes and are used extensively as solvents. Acetone, the most widely used ketone, is completely miscible with water, yet it dissolves a wide range of organic substances.

Carboxylic Acids and Esters

Carboxylic acids contain the *carboxyl* functional group, often written COOH. ∞ (Section 16.10) These weak acids are widely distributed in nature and are common in consumer products [▶ FIGURE 24.13(a)]. They are also important in the manufacture of polymers used to make fibers, films, and paints. ▼ FIGURE 24.14 shows the formulas of several carboxylic acids.

The common names of many carboxylic acids are based on their historical origins. Formic acid, for example, was first prepared by extraction from ants; its name is derived from the Latin word *formica*, “ant.”

Carboxylic acids can be produced by oxidation of alcohols in which the OH group is attached to a CH₂ group. Under appropriate conditions, the aldehyde may be isolated as the first product of oxidation, as in the sequence

where (O) represents any oxidant that can provide oxygen atoms. The air oxidation of ethanol to acetic acid is responsible for causing wines to turn sour, producing vinegar.

(a)

(b)

▲ FIGURE 24.13 Everyday carboxylic acids and esters. (a) Vinegar contains acetic acid; vitamin C is ascorbic acid; citrus fruits and tomatoes contain citric acid; and aspirin is acetylsalicylic acid (which is both an acid and an ester). (b) Many sunburn lotions contain the ester benzocaine; some nail polish removers contain ethyl acetate; vegetable oils are also esters.

GO FIGURE

Which of these substances have both a carboxylic acid functional group and an alcohol functional group?

◀ FIGURE 24.14 Structural formulas of common carboxylic acids. The monocarboxylic acids are generally referred to by their common names, given in blue type.

Acetic acid can also be produced by the reaction of methanol with carbon monoxide in the presence of a rhodium catalyst:

This reaction involves, in effect, the insertion of a carbon monoxide molecule between the CH_3 and OH groups. A reaction of this kind is called *carbonylation*.

Carboxylic acids can undergo condensation reactions with alcohols to form esters:

Esters are compounds in which the H atom of a carboxylic acid is replaced by a carbon-containing group:

Figure 24.13(b) shows some commercial products containing esters. The name of any ester consists of the name of the group contributed by the alcohol followed by the name of the group contributed by the carboxylic acid, with the *-ic* replaced by *-ate*. For example, the ester formed from ethyl alcohol, $\text{CH}_3\text{CH}_2\text{OH}$, and butyric acid, $\text{CH}_3(\text{CH}_2)_2\text{COOH}$, is

Notice that the chemical formula generally has the group originating from the acid written first, which is opposite of the way the ester is named.

Esters generally have very pleasant odors and are largely responsible for the pleasant aromas of fruit. Pentyl acetate ($\text{CH}_3\text{COOCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$), for example, is responsible for the odor of bananas.

An ester treated with an acid or a base in aqueous solution is *hydrolyzed*; that is, the molecule is split into an alcohol and a carboxylic acid or its anion:

The **hydrolysis** of an ester in the presence of a base is called **saponification**, a term that comes from the Latin word for soap, *sapon*. Naturally occurring esters include fats and oils, and in making soap an animal fat or a vegetable oil is boiled with a strong base. The resultant soap consists of a mixture of salts of long-chain carboxylic acids (called fatty acids), which form during the saponification reaction. ∞ (Section 13.6)

Soap has been manufactured and used for thousands of years. Directions for making soap from cassia oil were written on a Babylonian clay tablet around 2200 B.C. For a long time, soap was made by heating animal fat with wood ashes, which contain potassium

carbonate (also known as potash) and made the solution basic. [↔](#) (Section 16.9) The modern commercial process for making soap usually uses sodium hydroxide as the base. Using potassium hydroxide produces soft or liquid soaps.

SAMPLE EXERCISE 24.6 Naming Esters and Predicting Hydrolysis Products

In a basic aqueous solution, esters react with hydroxide ion to form the salt of the carboxylic acid and the alcohol from which the ester is constituted. Name each of the following esters, and indicate the products of their reaction with aqueous base.

SOLUTION

Analyze We are given two esters and asked to name them and to predict the products formed when they undergo hydrolysis (split into an alcohol and carboxylate ion) in basic solution.

Plan Esters are formed by the condensation reaction between an alcohol and a carboxylic acid. To name an ester, we must analyze its structure and determine the identities of the alcohol and acid from which it is formed. We can identify the alcohol by adding an OH to the alkyl group attached to the O atom of the carboxyl (COO) group. We can identify the acid by adding an H to the O atom of the carboxyl group. We have learned that the first part of an ester name indicates the alcohol portion and the second indicates the acid portion. The name conforms to how the ester undergoes hydrolysis in base, reacting with base to form an alcohol and a carboxylate anion.

Solve

(a) This ester is derived from ethanol ($\text{CH}_3\text{CH}_2\text{OH}$) and benzoic acid ($\text{C}_6\text{H}_5\text{COOH}$). Its name is therefore ethyl benzoate. The net ionic equation for reaction of ethyl benzoate with hydroxide ion is

The products are benzoate ion and ethanol.

(b) This ester is derived from phenol ($\text{C}_6\text{H}_5\text{OH}$) and butanoic acid (commonly called butyric acid) ($\text{CH}_3\text{CH}_2\text{CH}_2\text{COOH}$). The residue from the phenol is called the phenyl group. The ester is therefore named phenyl butyrate. The net ionic equation for the reaction of phenyl butyrate with hydroxide ion is

The products are butyrate ion and phenol.

PRACTICE EXERCISE

Write the condensed structural formula for the ester formed from propyl alcohol and propionic acid.

Amines and Amides

Amines are compounds in which one or more of the hydrogens of ammonia (NH₃) are replaced by an alkyl group:

As we have seen earlier, they are the most common organic bases. ∞ (Section 16.7)

An amine with at least one H bonded to N can undergo a condensation reaction with a carboxylic acid to form an **amide**, which contains the carbonyl group (C=O) attached to N (Table 24.6):

We may consider the amide functional group to be derived from a carboxylic acid with an NRR' group replacing the OH of the acid, as in these examples:

The amide linkage

where R and R' are organic groups, is the key functional group in proteins, as we will see in Section 24.7.

24.5 CHIRALITY IN ORGANIC CHEMISTRY

A molecule possessing a nonsuperimposable mirror image is termed **chiral** (Greek *cheir*, “hand”). ∞ (Section 23.4) *Compounds containing carbon atoms with four different attached groups are inherently chiral.* A carbon atom with four different attached groups is called a *chiral center*. For example, consider 2-bromopentane:

GO FIGURE

If you replace Br with CH₃, will the compound be chiral?

▲ **FIGURE 24.15** The two enantiomeric forms of 2-bromopentane. The mirror-image isomers are not superimposable on each other.

All four groups attached to C2 are different, making that carbon a chiral center. ◀ **FIGURE 24.15** illustrates the nonsuperimposable mirror images of this molecule. Imagine moving the molecule shown to the left of the mirror over to the right of the mirror. If you then turn it in every possible way, you will conclude that it cannot be superimposed on the molecule shown to the right of the mirror. Nonsuperimposable mirror images are called either *optical isomers* or *enantiomers*. ∞ (Section 23.4) Organic chemists use the labels *R* and *S* to distinguish the two forms. We need not go into the rules for deciding on the labels.

The two members of an enantiomer pair have identical physical properties and identical chemical properties when they react with nonchiral reagents. Only in a chiral environment do they

behave differently from each other. One interesting property of chiral substances is that their solutions may rotate the plane of polarized light, as explained in Section 23.4.

Chirality is common in organic substances. It is not often observed, however, because when a chiral substance is synthesized in a typical reaction, the two enantiomers are formed in precisely the same quantity. The resulting mixture is called a *racemic mixture*, and it does not rotate the plane of polarized light because the two forms rotate the light to equal extents in opposite directions. ∞ (Section 23.4)

Many drugs are chiral substances. When a drug is administered as a racemic mixture, often only one enantiomer has beneficial results. The other is either inert, or nearly so, or may even have a harmful effect. For example, the drug (*R*)-albuterol (► FIGURE 24.16) is a bronchodilator used to relieve the symptoms of asthma. The enantiomer (*S*)-albuterol is not only ineffective as a bronchodilator but also actually counters the effects of (*R*)-albuterol. As another example, the nonsteroidal analgesic ibuprofen is a chiral molecule usually sold as the racemic mixture. However, a preparation consisting of just the more active enantiomer, (*S*)-ibuprofen (► FIGURE 24.17), relieves pain and reduces inflammation more rapidly than the racemic mixture. For this reason, the chiral version of the drug may in time come to replace the racemic one.

▲ GIVE IT SOME THOUGHT

What are the requirements on the four groups attached to a carbon atom in order that it be a chiral center?

24.6 INTRODUCTION TO BIOCHEMISTRY

The functional groups discussed in Section 24.4 generate a vast array of molecules with very specific chemical reactivities. Nowhere is this specificity more apparent than in *biochemistry*—the chemistry of living organisms.

Before we discuss specific biochemical molecules, we can make some general observations. Many biologically important molecules are quite large, because organisms build biomolecules from smaller, simpler substances readily available in the biosphere. The synthesis of large molecules requires energy because most of the reactions are endothermic. The ultimate source of this energy is the Sun. Animals have essentially no capacity for using solar energy directly, however, and so depend on plant photosynthesis to supply the bulk of their energy needs. ∞ (Section 23.3)

In addition to requiring large amounts of energy, living organisms are highly organized. In thermodynamic terms, this high degree of organization means that the entropy of living systems is much lower than that of the raw materials from which the systems formed. Thus, living systems must continuously work against the spontaneous tendency toward increased entropy.

In the “Chemistry and Life” essays that appear throughout this text, we have introduced you to some important biochemical applications of fundamental chemical ideas. The remainder of this chapter will serve as only a brief introduction to other aspects of biochemistry. Nevertheless, you will see some patterns emerging. Hydrogen bonding (Section 11.2), for example, is critical to the function of many biochemical systems, and the geometry of molecules (Section 9.1) can govern their biological importance and activity. Many of the large molecules in living systems are polymers (Section 12.8) of much smaller molecules. These **biopolymers** can be classified into three broad categories: proteins, polysaccharides (carbohydrates), and nucleic acids. Lipids are another common class of molecules in living systems, but they are usually large molecules, not biopolymers.

24.7 PROTEINS

Proteins are macromolecules present in all living cells. About 50% of your body’s dry mass is protein. Some proteins are structural components in animal tissues; they are a key part of skin, nails, cartilage, and muscles. Other proteins catalyze reactions, transport oxygen, serve as hormones to regulate specific body processes, and perform other tasks. Whatever their function, all proteins are chemically similar, being composed of smaller molecules called *amino acids*.

▲ FIGURE 24.16 (*R*)-Albuterol. This compound, which acts as a bronchodilator in patients with asthma, is one member of an enantiomer pair. The other member, (*S*)-albuterol, does not have the same physiological effect.

▲ FIGURE 24.17 (*S*)-Ibuprofen. For relieving pain and reducing inflammation, the ability of this enantiomer far outweighs that of the (*R*) isomer.

Amino Acids

An **amino acid** is a molecule containing an amine group, —NH_2 , and a carboxylic acid group, —COOH . The building blocks of all proteins are α -amino acids, where the α (alpha) indicates that the amino group is located on the carbon atom immediately adjacent to the carboxylic acid group. Thus, there is always one carbon atom between the amino group and the carboxylic acid group.

The general formula for an α -amino acid is represented by

The doubly ionized form, called a *zwitterion*, usually predominates at near-neutral pH values. This form is a result of the transfer of a proton from the carboxylic acid group to the amine group. ∞ (Section 16.10: “Chemistry and Life: The Amphiprotic Behavior of Amino Acids”)

Amino acids differ from one another in the nature of their R groups. Twenty-two amino acids have been identified in nature, and ► **FIGURE 24.18** shows the 20 of these 22 that are found in humans. Our bodies can synthesize 10 of these 20 amino acids in sufficient amounts for our needs. The other 10 must be ingested and are called *essential amino acids* because they are necessary components of our diet.

The α -carbon atom of the amino acids, which is the carbon between the amino and carboxylate groups, has four different groups attached to it. The amino acids are thus chiral (except for glycine, which has two hydrogens attached to the central carbon). For historical reasons, the two enantiomeric forms of amino acids are often distinguished by the labels D (from the Latin *dexter*, “right”) and L (from the Latin *laevus*, “left”). Nearly all the chiral amino acids found in living organisms have the L configuration at the chiral center. The principal exceptions to the dominance of L amino acids in nature are the proteins that make up the cell walls of bacteria, which can contain considerable quantities of the D isomers.

Polypeptides and Proteins

Amino acids are linked together into proteins by amide groups (Table 24.6):

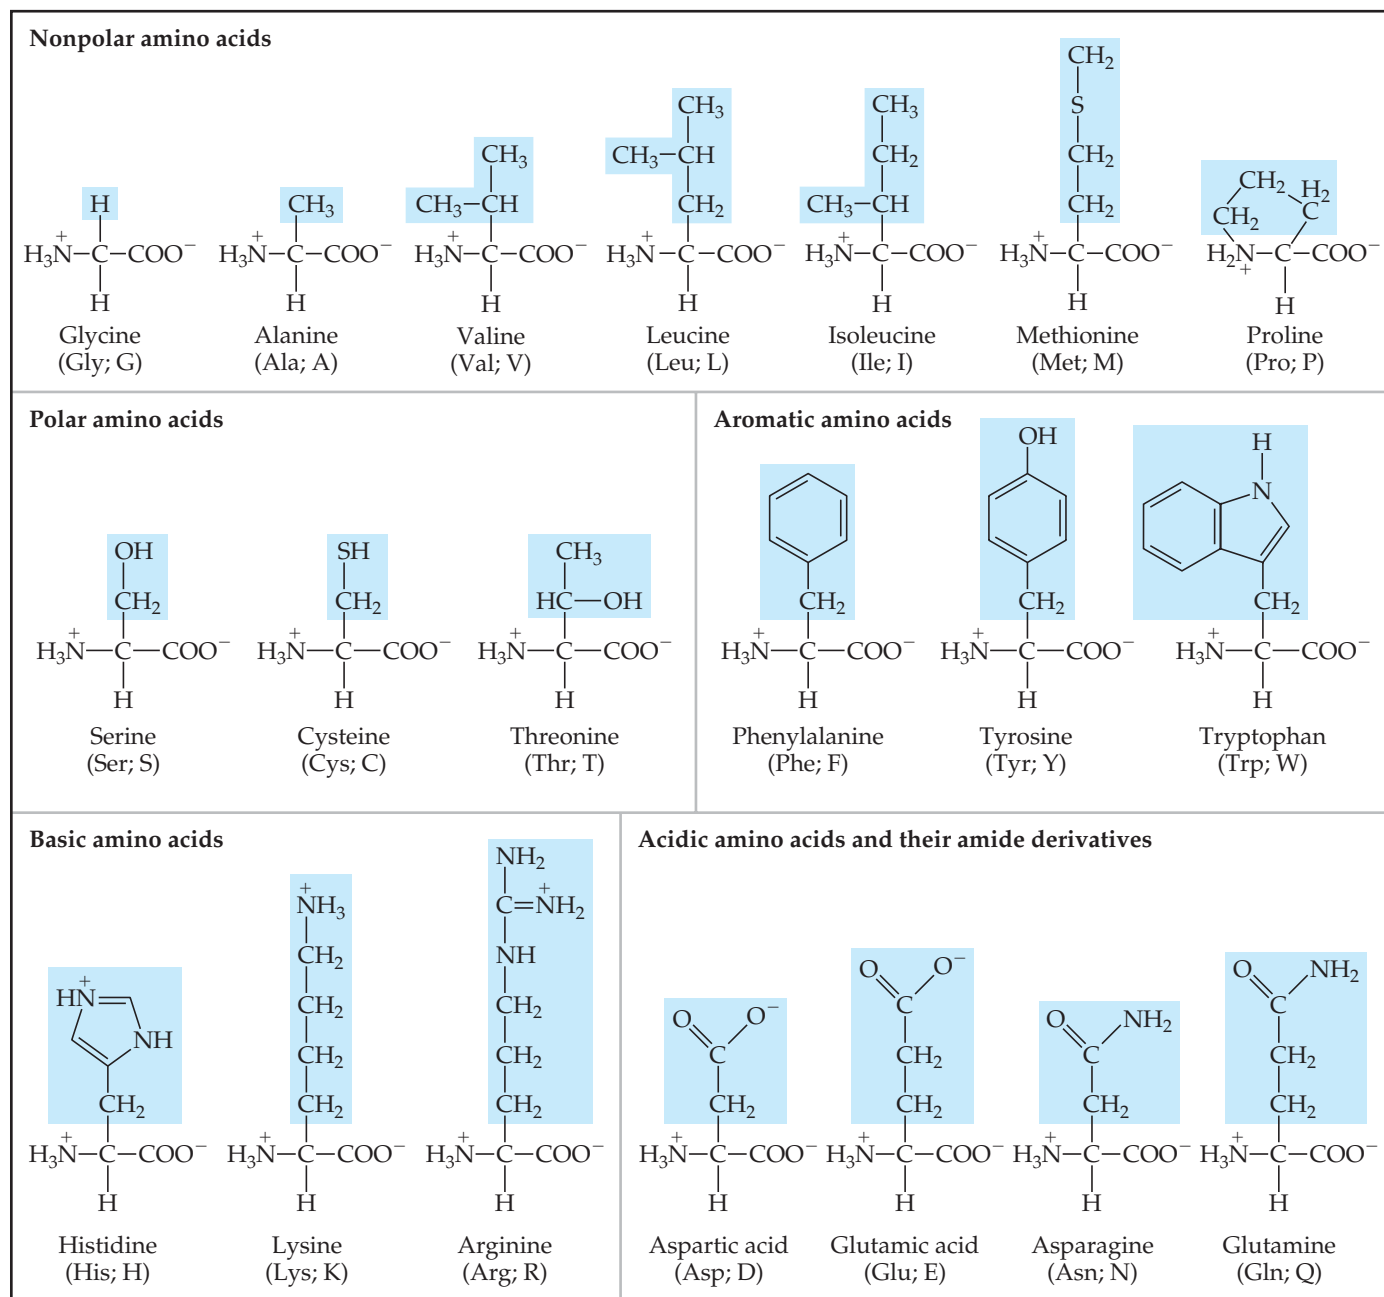

Each amide group is called a **peptide bond** when it is formed by amino acids. A peptide bond is formed by a condensation reaction between the carboxyl group of one amino acid and the amino group of another amino acid. Alanine and glycine, for example, form the dipeptide glycylalanine:

GO FIGURE

Which group of amino acids has a net positive charge at pH 7?

▲ **FIGURE 24.18** The 20 amino acids found in the human body. The acids are shown in the zwitterionic form in which they exist in water at near-neutral pH values.

The amino acid that furnishes the carboxyl group for peptide-bond formation is named first, with a *-yl* ending; then the amino acid furnishing the amino group is named. Using the abbreviations shown in Figure 24.18, glycylalanine can be abbreviated as either Gly-Ala or GA. In this notation, it is understood that the unreacted amino group is on the left and the unreacted carboxyl group on the right.

The artificial sweetener *aspartame* (► **FIGURE 24.19**) is the methyl ester of the dipeptide formed from the amino acids aspartic acid and phenylalanine.

▲ **FIGURE 24.19** Sweet stuff. The artificial sweetener aspartame is the methyl ester of a dipeptide.

SAMPLE EXERCISE 24.7 Drawing the Structural Formula of a Tripeptide

Draw the structural formula for alanylglycylserine.

SOLUTION

Analyze We are given the name of a substance with peptide bonds and asked to write its structural formula.

Plan The name of this substance suggests that three amino acids—alanine, glycine, and serine—have been linked together, forming a *tripeptide*. Note that the ending *-yl* has been added to each amino acid except for the last one, serine. By convention, the sequence of amino acids in peptides and proteins is written from the nitrogen end to the carbon end: The first-named amino acid (alanine, in this case) has a free amino group and the last-named one (serine) has a free carboxyl group.

Solve We first combine the carboxyl group of alanine with the amino group of glycine to form a peptide bond and then the carboxyl group of glycine with the amino group of serine to form another peptide bond:

We can abbreviate this tripeptide as either Ala-Gly-Ser or AGS.

PRACTICE EXERCISE

Name the dipeptide

and give the two ways of writing its abbreviation.

Answer: serylaspatic acid; Ser-Asp, SD.

Polypeptides are formed when a large number of amino acids are linked together by peptide bonds. Proteins are linear (that is, unbranched) polypeptide molecules with molecular weights ranging from about 6000 to over 50 million amu. Because up to 22 different amino acids are linked together in proteins and because proteins consist of hundreds of amino acids, the number of possible arrangements of amino acids within proteins is virtually limitless.

Protein Structure

The sequence of amino acids along a protein chain is called its **primary structure** and gives the protein its unique identity. A change in even one amino acid can alter the biochemical characteristics of the protein. For example, sickle-cell anemia is a genetic disorder resulting from a single replacement in a protein chain in hemoglobin. The chain that is affected contains 146 amino acids. The substitution of an amino acid with a hydrocarbon side chain for one that has an acidic functional group in the side chain alters the solubility properties of the hemoglobin, and normal blood flow is impeded. ∞ (Section 13.6: “Chemistry and Life: Sickle-Cell Anemia”)

Proteins in living organisms are not simply long, flexible chains with totally random shapes. Rather, the chains self-assemble into structures based on the intermolecular forces we learned about in Chapter 11. This self-assembling leads to a protein’s **secondary structure**, which refers to how segments of the protein chain are oriented in a regular pattern, as seen in ► **FIGURE 24.20**.

◀ **FIGURE 24.20** The four levels of structure of proteins.

One of the most important and common secondary structure arrangements is the **α -helix**. As the α -helix of Figure 24.20 shows, the helix is held in position by hydrogen bonds between amide H atoms and carbonyl O atoms. The pitch of the helix and its diameter must be such that (1) no bond angles are strained and (2) the N—H and C=O functional groups on adjacent turns are in proper position for hydrogen bonding. An arrangement of this kind is possible for some amino acids along the chain but not for others. Large protein molecules may contain segments of the chain that have the α -helical arrangement interspersed with sections in which the chain is in a random coil.

The other common secondary structure of proteins is the beta (β) **sheet**. Beta sheets are made of two or more strands of peptides that hydrogen-bond from an amide H in one strand to a carbonyl O in the other strand (Figure 24.20).

▲ GIVE IT SOME THOUGHT

If you heat a protein to break the intramolecular hydrogen bonds, will you maintain the α -helical or β -sheet structure?

Proteins are not active biologically unless they are in a particular shape in solution. The process by which the protein adopts its biologically active shape is called **folding**. The shape of a protein in its folded form—determined by all the bends, kinks, and sections of rodlike α -helical, β -sheet, or flexible coil components—is called the **tertiary structure**.

Figure 23.14 shows the tertiary structure of myoglobin, a protein with a molecular weight of about 18,000 amu and containing one heme group. Some sections of this protein consist of α -helices.

Myoglobin is a *globular protein*, one that folds into a compact, roughly spherical shape. Globular proteins are generally soluble in water and are mobile within cells. They have non-structural functions, such as combating the invasion of foreign objects, transporting and storing oxygen, and acting as catalysts. The *fibrous proteins* form a second class of proteins. In these substances the long coils align more or less in parallel to form long, water-insoluble fibers. Fibrous proteins provide structural integrity and strength to many kinds of tissue and are the main components of muscle, tendons, and hair. The largest known proteins, in excess of 27,000 amino acids long, are muscle proteins.

The tertiary structure of a protein is maintained by many different interactions. Certain foldings of the protein chain lead to lower-energy (more stable) arrangements than do other folding patterns. For example, a globular protein dissolved in aqueous solution folds in such a way that the nonpolar hydrocarbon portions are tucked within the molecule, away from the polar water molecules. Most of the more polar acidic and basic side chains, however, project into the solution, where they can interact with water molecules through ion–dipole, dipole–dipole, or hydrogen-bonding interactions.

Some proteins are assemblies of more than one polypeptide chain. Each chain has its own tertiary structure, and two or more of these tertiary subunits aggregate into a larger functional macromolecule. The way the tertiary subunits are arranged is called the **quaternary structure** of the protein (Figure 24.20). For example, hemoglobin, the oxygen-carrying protein of red blood cells, consists of four tertiary subunits. Each subunit contains a component called a heme with an iron atom that binds oxygen as depicted in Figure 23.15. The quaternary structure is maintained by the same types of interactions that maintain the tertiary structure.

▲ FIGURE 24.21 Linear structure of the carbohydrates glucose and fructose.

24.8 CARBOHYDRATES

Carbohydrates are an important class of naturally occurring substances found in both plant and animal matter. The name **carbohydrate** (“hydrate of carbon”) comes from the empirical formulas for most substances in this class, which can be written as $C_x(H_2O)_y$. For example, **glucose**, the most abundant carbohydrate, has the molecular formula $C_6H_{12}O_6$, or $C_6(H_2O)_6$. Carbohydrates are not really hydrates of carbon; rather, they are polyhydroxy aldehydes and ketones. Glucose, for example, is a six-carbon aldehyde sugar, whereas *fructose*, the sugar that occurs widely in fruit, is a six-carbon ketone sugar (◀ FIGURE 24.21).

The glucose molecule, having both alcohol and aldehyde functional groups and a reasonably long and flexible backbone, can form a six-member-ring structure, as shown in ▼ FIGURE 24.22. In fact, in an aqueous solution only a small percentage of the

► FIGURE 24.22 Cyclic glucose has an α form and a β form.

glucose molecules are in the open-chain form. Although the ring is often drawn as if it were planar, the molecules are actually nonplanar because of the tetrahedral bond angles around the C and O atoms of the ring.

Figure 24.22 shows that the ring structure of glucose can have two relative orientations. In the α form the OH group on C1 and the CH₂OH group on C5 point in opposite directions, and in the β form they point in the same direction. Although the difference between the α and β forms might seem small, it has enormous biological consequences, including the vast difference in properties between starch and cellulose.

Fructose can cyclize to form either five- or six-member rings. The five-member ring forms when the C5 OH group reacts with the C2 carbonyl group:

The six-member ring results from the reaction between the C6 OH group and the C2 carbonyl group.

SAMPLE EXERCISE 24.8 Identifying Chiral Centers

How many chiral carbon atoms are there in the open-chain form of glucose (Figure 24.21)?

SOLUTION

Analyze We are given the structure of glucose and asked to determine the number of chiral carbons in the molecule.

Plan A chiral carbon has four different groups attached (Section 24.5). We need to identify those carbon atoms in glucose.

Solve Carbons 2, 3, 4, and 5 each have four different groups attached to them:

Thus, there are four chiral carbon atoms in the glucose molecule.

PRACTICE EXERCISE

How many chiral carbon atoms are there in the open-chain form of fructose (Figure 24.21)?

Answer: three

Disaccharides

Both glucose and fructose are examples of **monosaccharides**, simple sugars that cannot be broken into smaller molecules by hydrolysis with aqueous acids. Two monosaccharide units can be linked together by a condensation reaction to form a **disaccharide**. The structures of two common disaccharides, *sucrose* (table sugar) and *lactose* (milk sugar), are shown in ► **FIGURE 24.23**.

▲ FIGURE 24.23 Two disaccharides.

The word *sugar* makes us think of sweetness. All sugars are sweet, but they differ in the degree of sweetness we perceive when we taste them. Sucrose is about six times sweeter than lactose, slightly sweeter than glucose, but only about half as sweet as fructose. Disaccharides can be reacted with water (hydrolyzed) in the presence of an acid catalyst to form monosaccharides. When sucrose is hydrolyzed, the mixture of glucose and fructose that forms, called *invert sugar*,* is sweeter to the taste than the original sucrose. The sweet syrup present in canned fruits and candies is largely invert sugar formed from hydrolysis of added sucrose.

Polysaccharides

Polysaccharides are made up of many monosaccharide units joined together. The most important polysaccharides are starch, glycogen, and cellulose, all three of which are formed from repeating glucose units.

Starch is not a pure substance. The term refers to a group of polysaccharides found in plants. Starches serve as a major method of food storage in plant seeds and tubers. Corn, potatoes, wheat, and rice all contain substantial amounts of starch. These plant products serve as major sources of needed food energy for humans. Enzymes in the digestive system catalyze the hydrolysis of starch to glucose.

Some starch molecules are unbranched chains, whereas others are branched.

▼ FIGURE 24.24(a) illustrates an unbranched starch structure. Notice, in particular,

▲ FIGURE 24.24 Structures of (a) starch and (b) cellulose.

*The term *invert sugar* comes from the fact that rotation of the plane of polarized light by the glucose-fructose mixture is in the opposite direction, or inverted, from that of the sucrose solution.

that the glucose units are in the α form with the bridging oxygen atoms pointing in one direction and the CH_2OH groups pointing in the opposite direction

Glycogen is a starchlike substance synthesized in the animal body. Glycogen molecules vary in molecular weight from about 5000 to more than 5 million amu. Glycogen acts as a kind of energy bank in the body. It is concentrated in the muscles and liver. In muscles it serves as an immediate source of energy; in the liver it serves as a storage place for glucose and helps to maintain a constant glucose level in the blood.

Cellulose [Figure 24.24(b)] forms the major structural unit of plants. Wood is about 50% cellulose; cotton fibers are almost entirely cellulose. Cellulose consists of an unbranched chain of glucose units, with molecular weights averaging more than 500,000 amu. At first glance this structure looks very similar to that of starch. In cellulose, however, the glucose units are in the β form with each bridging oxygen atom pointing in the same direction as the CH_2OH group in the ring to its left.

Because the individual glucose units have different relationships to one another in starch and cellulose, enzymes that readily hydrolyze starches do not hydrolyze cellulose. Thus, you might eat a pound of cellulose and receive no caloric value from it even though the heat of combustion per unit mass is essentially the same for both cellulose and starch. A pound of starch, in contrast, would represent a substantial caloric intake. The difference is that the starch is hydrolyzed to glucose, which is eventually oxidized with release of energy. However, enzymes in the body do not readily hydrolyze cellulose, so it passes through the digestive system relatively unchanged. Many bacteria contain enzymes, called cellulases, that hydrolyze cellulose. These bacteria are present in the digestive systems of grazing animals, such as cattle, that use cellulose for food.

GIVE IT SOME THOUGHT

Which type of linkage, α or β , would you expect to join the sugar molecules of glycogen?

24.9 | LIPIDS

Lipids are a diverse class of nonpolar biological molecules used by organisms for long-term energy storage (fats, oils) and as elements of biological structures (phospholipids, cell membranes, waxes).

Fats

Fats are lipids derived from glycerol and fatty acids. Glycerol is an alcohol with three OH groups. Fatty acids are carboxylic acids (RCOOH) in which R is a hydrocarbon chain, usually 16 to 19 carbon atoms in length. Glycerol and fatty acids undergo condensation reactions to form ester linkages as shown in ► **FIGURE 24.25**. Three fatty acid molecules join to a glycerol. Although the three fatty acids in a fat can be the same, as they are in Figure 24.25, it is also possible that a fat contains three different fatty acids.

Lipids with saturated fatty acids are called saturated fats and are commonly solids at room temperature (such as butter and shortening). Unsaturated fats contain one or more double bonds in their carbon-carbon chains. The *cis* and *trans* nomenclature we learned for alkenes applies: *Trans* fats have H atoms on the opposite sides of the $\text{C}=\text{C}$ double bond, and *cis* fats have H atoms on the same sides of the $\text{C}=\text{C}$ double bond. Unsaturated fats (such as olive oil and peanut oil) are usually liquid at room temperature and are more often found in plants. For example, the major component (approximately 60 to 80%) of olive oil is oleic acid, *cis*- $\text{CH}_3(\text{CH}_2)_7\text{CH}=\text{CH}(\text{CH}_2)_7\text{COOH}$.

Oleic acid is an example of a *monounsaturated* fatty acid, meaning it has only one carbon-carbon double bond in the chain. In contrast, *polyunsaturated* fatty acids have more than one carbon-carbon double bond in the chain.

For humans, *trans* fats are not nutritionally required, which is why some governments are moving to ban them in foods. How, then, do *trans* fats end up in our food? The process that converts unsaturated fats (such as oils) into saturated fats (such as shortening) is hydrogenation. ∞ (Section 24.3) The by-products of this hydrogenation process include *trans* fats.

GO FIGURE

What structural features of a fat molecule cause it to be insoluble in water?

▲ FIGURE 24.25 Structure of a fat.

Some of the fatty acids essential for human health must be available in our diets because our metabolism cannot synthesize them. These essential fatty acids are ones that have the carbon-carbon double bonds either three carbons or six carbons away from the $-\text{CH}_3$ end of the chain. These are called omega-3 and omega-6 fatty acids, where *omega* refers to the last carbon in the chain (the carboxylic acid carbon is considered the first, or alpha, one).

Phospholipids

Phospholipids are similar in chemical structure to fats but have only two fatty acids attached to a glycerol. The third alcohol group of glycerol is joined to a phosphate group (► FIGURE 24.26). The phosphate group can be also attached to a small charged or polar group, such as choline, as shown in the figure. The diversity in phospholipids is based on differences in their fatty acids and in the groups attached to the phosphate group.

In water, phospholipids cluster together with their charged polar heads facing the water and their nonpolar tails facing inward. The phospholipids thus form a bilayer that is a key component of cell membranes (► FIGURE 24.27).

24.10 NUCLEIC ACIDS

Nucleic acids are a class of biopolymers that are the chemical carriers of an organism's genetic information. **Deoxyribonucleic acids (DNA)** are huge molecules whose molecular weights may range from 6 million to 16 million amu. **Ribonucleic acids (RNA)** are smaller molecules, with molecular weights in the range of 20,000 to 40,000 amu. Whereas DNA is found primarily in the nucleus of the cell, RNA is found mostly outside the nucleus in the *cytoplasm*, the nonnuclear material enclosed by the cell membrane. DNA stores the genetic information of the cell and specifies which proteins the cell can synthesize. RNA carries the information stored by DNA out of the cell nucleus into the cytoplasm, where the information is used in protein synthesis.

▲ **FIGURE 24.26** Structure of a phospholipid.

GO FIGURE

Why do phospholipids form bilayers but not monolayers in water?

◀ **FIGURE 24.27** The cell membrane. Living cells are encased in membranes typically made of phospholipid bilayers. The bilayer structure is stabilized by the favorable interactions of the hydrophobic tails of the phospholipids, which point away from both the water inside the cell and the water outside the cell, while the charged head groups face the two water environments.

▲ **FIGURE 24.28** A nucleotide. Structure of deoxyadenylic acid, the nucleotide formed from phosphoric acid, deoxyribose, and the organic base adenine.

The monomers of nucleic acids, called **nucleotides**, are formed from a five-carbon sugar, a nitrogen-containing organic base, and a phosphate group. An example is shown in ◀ **FIGURE 24.28**.

The five-carbon sugar in RNA is *ribose*, and that in DNA is *deoxyribose*:

Deoxyribose differs from ribose only in having one fewer oxygen atom at carbon 2.

There are five nitrogen-containing bases in nucleic acids:

The first three bases shown here are found in both DNA and RNA. Thymine occurs only in DNA, and uracil occurs only in RNA. In either nucleic acid, each base is attached to a five-carbon sugar through a bond to the nitrogen atom shown in color.

The nucleic acids RNA and DNA are *polynucleotides* formed by condensation reactions between a phosphoric acid OH group on one nucleotide and a sugar OH group on another nucleotide. Thus, the polynucleotide strand has a backbone consisting of alternating sugar and phosphate groups with the bases extending off the chain as side groups (◀ **FIGURE 24.29**).

The DNA strands wind together in a **double helix** (▶ **FIGURE 24.30**). The two strands are held together by attractions between bases (represented by T, A, C, and G). These attractions involve dispersion forces, dipole–dipole forces, and hydrogen bonds. ∞ (Section 11.2) As shown in ▶ **FIGURE 24.31**, the structures of thymine and adenine make them perfect partners for hydrogen bonding. Likewise, cytosine and guanine form ideal hydrogen-bonding partners. We say that thymine and adenine are *complementary* to each other and cytosine and guanine are *complementary* to each other. In the double-helix structure, therefore, each thymine on one strand is opposite an adenine on the other strand, and each cytosine is opposite a guanine. The double-helix structure with complementary bases on the two strands is the key to understanding how DNA functions.

The two strands of DNA unwind during cell division, and new complementary strands are constructed on the unraveling strands (▶ **FIGURE 24.32**). This process results in two identical double-helix DNA structures, each containing one strand from the original structure and one new strand. This replication allows genetic information to be transmitted when cells divide.

The structure of DNA is also the key to understanding protein synthesis, the means by which viruses infect cells, and many other problems of central importance to modern biology. These themes are beyond the scope of this book. If you take courses in the life sciences, however, you will learn a good deal about such matters.

GO FIGURE
Is DNA positively charged, negatively charged, or neutral in aqueous solution at pH 7?

GO FIGURE

Which pair of complementary bases, AT or GC, would you expect to bind more strongly?

▲ FIGURE 24.31 Hydrogen bonding between complementary bases.

◀ FIGURE 24.32 DNA replication. The original DNA double helix partially unwinds, and new nucleotides line up on each strand in complementary fashion. Hydrogen bonds help align the new nucleotides with the original DNA chain. When the new nucleotides are joined by condensation reactions, two identical double-helix DNA molecules result.

SAMPLE INTEGRATIVE EXERCISE Putting Concepts Together

Pyruvic acid,

is formed in the body from carbohydrate metabolism. In muscles, it is reduced to lactic acid in the course of exertion. The acid-dissociation constant for pyruvic acid is 3.2×10^{-3} . (a) Why does pyruvic acid have a higher acid-dissociation constant than acetic acid? (b) Would you expect pyruvic acid to exist primarily as the neutral acid or as dissociated ions in muscle tissue, assuming a pH of about 7.4 and an acid concentration of $2 \times 10^{-4} \text{ M}$? (c) What would you predict for the solubility properties of pyruvic acid? Explain. (d) What is the hybridization of

each carbon atom in pyruvic acid? (e) Assuming H atoms as the reducing agent, write a balanced chemical equation for the reduction of pyruvic acid to lactic acid (Figure 24.14). (Although H atoms do not exist as such in biochemical systems, biochemical reducing agents deliver hydrogen for such reductions.)

SOLUTION

(a) The acid-dissociation constant for pyruvic acid should be somewhat greater than that of acetic acid because the carbonyl function on the α -carbon atom of pyruvic acid exerts an electron-withdrawing effect on the carboxylic acid group. In the C—O—H bond system the electrons are shifted from H, facilitating loss of the H as a proton. ∞ (Section 16.10)

(b) To determine the extent of ionization, we first set up the ionization equilibrium and equilibrium-constant expression. Using HPv as the symbol for the acid, we have

Let $[\text{Pv}^-] = x$. Then the concentration of undissociated acid is $2 \times 10^{-4} - x$. The concentration of $[\text{H}^+]$ is fixed at 4.0×10^{-8} (the antilog of the pH value). Substituting, we obtain

$$3.2 \times 10^{-3} = \frac{[4.0 \times 10^{-8}][x]}{[2 \times 10^{-4} - x]}$$

Solving for x , we obtain $x[3.2 \times 10^{-3} + 4.0 \times 10^{-8}] = 6.4 \times 10^{-7}$.

The second term in the brackets is negligible compared to the first, so

$$x = [\text{Pv}^-] = 6.4 \times 10^{-7} / 3.2 \times 10^{-3} = 2 \times 10^{-4} \text{ M}$$

This is the initial concentration of acid, which means that essentially all the acid has dissociated. We might have expected this result because the acid is quite dilute and the acid-dissociation constant is fairly high.

(c) Pyruvic acid should be quite soluble in water because it has polar functional groups and a small hydrocarbon component. It is miscible with water, ethanol, and diethyl ether.

(d) The methyl group carbon has sp^3 hybridization. The carbon of the carbonyl group has sp^2 hybridization because of the double bond to oxygen. Similarly, the carboxylic acid carbon is sp^2 hybridized.

(e) The balanced chemical equation for this reaction is

Essentially, the ketonic functional group has been reduced to an alcohol.

STRATEGIES IN CHEMISTRY

WHAT NOW?

If you are reading this box, you have made it to the end of our text. We congratulate you on the tenacity and dedication that you have exhibited to make it this far!

As an epilogue, we offer the ultimate study strategy in the form of a question: What do you plan to do with the knowledge of chemistry that you have gained thus far in your studies? Many of you will enroll in additional courses in chemistry as part of your required curriculum. For others, this will be the last formal course in chemistry that you will take. Regardless of the career path you plan to take—whether it is chemistry, one of the biomedical fields, engineering, the liberal arts, or another field—we hope that this text has increased your appreciation of the chemistry in the world around you. If you pay attention, you will be aware of encounters with chemistry on a daily basis, from food and pharmaceutical labels to gasoline pumps, sports equipment to news reports.

We have also tried to give you a sense that chemistry is a dynamic, continuously changing science. Research chemists synthesize new compounds, develop new reactions, uncover chemical properties that were previously unknown, find new applications for known compounds, and refine theories. The understanding of biological systems in terms of the underlying chemistry has become increasingly important as new levels of complexity are uncovered. You may wish to participate in the fascinating venture of chemical research by taking part in an undergraduate research program. Given all the answers that chemists seem to have, you may be surprised at the large number of questions that they still find to ask.

Finally, we hope you have enjoyed using this textbook. We certainly enjoyed putting so many of our thoughts about chemistry on paper. We truly believe it to be the central science, one that benefits all who learn about it and from it.

CHAPTER SUMMARY AND KEY TERMS

INTRODUCTION AND SECTION 24.1 This chapter introduces **organic chemistry**, which is the study of carbon compounds (typically compounds containing carbon-carbon bonds), and **biochemistry**, which is the study of the chemistry of living organisms. We have encountered many aspects of organic chemistry in earlier chapters. Carbon forms four bonds in its stable compounds. The C—C single bonds and the C—H bonds tend to have low reactivity. Those bonds that have a high electron density (such as multiple bonds or bonds with an atom of high electronegativity) tend to be the sites of reactivity in an organic compound. These sites of reactivity are called **functional groups**.

SECTION 24.2 The simplest types of organic compounds are hydrocarbons, those composed of only carbon and hydrogen. There are four major kinds of hydrocarbons: alkanes, alkenes, alkynes, and aromatic hydrocarbons. **Alkanes** are composed of only C—H and C—C single bonds. **Alkenes** contain one or more carbon-carbon double bonds. **Alkynes** contain one or more carbon-carbon triple bonds. **Aromatic hydrocarbons** contain cyclic arrangements of carbon atoms bonded through both σ and delocalized π bonds. Alkanes are saturated hydrocarbons; the others are unsaturated.

Alkanes may form straight-chain, branched-chain, and cyclic arrangements. Isomers are substances that possess the same molecular formula but differ in the arrangements of atoms. In **structural isomers** the bonding arrangements of the atoms differ. Different isomers are given different systematic names. The naming of hydrocarbons is based on the longest continuous chain of carbon atoms in the structure. The locations of **alkyl groups**, which branch off the chain, are specified by numbering along the carbon chain.

Alkanes with ring structures are called **cycloalkanes**. Alkanes are relatively unreactive. They do, however, undergo combustion in air, and their chief use is as sources of heat energy produced by combustion.

SECTION 24.3 The names of alkenes and alkynes are based on the longest continuous chain of carbon atoms that contains the multiple bond, and the location of the multiple bond is specified by a numerical prefix. Alkenes exhibit not only structural isomerism but geometric (*cis-trans*) isomerism as well. In **geometric isomers** the bonds are the same, but the molecules have different geometries. Geometric isomerism is possible in alkenes because rotation about the C=C double bond is restricted.

Alkenes and alkynes readily undergo **addition reactions** to the carbon-carbon multiple bonds. Additions of acids, such as HBr, proceed via a rate-determining step in which a proton is transferred to one of the alkene or alkyne carbon atoms. Addition reactions are difficult to carry out with aromatic hydrocarbons, but **substitution reactions** are easily accomplished in the presence of catalysts.

SECTION 24.4 The chemistry of organic compounds is dominated by the nature of their functional groups. The functional groups we have considered are

R, R', and R'' represent hydrocarbon groups—for example, methyl (CH₃) or phenyl (C₆H₅).

Alcohols are hydrocarbon derivatives containing one or more OH groups. **Ethers** are formed by a condensation reaction of two molecules of alcohol. Several functional groups contain the **carbonyl (C=O) group**, including **aldehydes**, **ketones**, **carboxylic acids**, **esters**, and **amides**. Aldehydes and ketones can be produced by oxidation of certain alcohols. Further oxidation of the aldehydes produces carboxylic acids. Carboxylic acids can form esters by a condensation reaction with alcohols, or they can form amides by a condensation reaction with amines. Esters undergo **hydrolysis (saponification)** in the presence of strong bases.

SECTION 24.5 Molecules that possess nonsuperimposable mirror images are termed **chiral**. The two nonsuperimposable forms of a chiral molecule are called **enantiomers**. In carbon compounds a chiral center is created when all four groups bonded to a central carbon atom are different, as in 2-bromobutane. Many of the molecules occurring in living systems, such as the amino acids, are chiral and exist in nature in only one enantiomeric form. Many drugs of importance in human medicine are chiral, and the enantiomers may produce very different biochemical effects. For this reason, synthesis of only the effective isomers of chiral drugs has become a high priority.

SECTIONS 24.6 AND 24.7 Many of the molecules that are essential for life are large natural polymers that are constructed from smaller molecules called monomers. Three of these **biopolymers** are considered in this chapter: proteins, polysaccharides (carbohydrates), and nucleic acids.

Proteins are polymers of **amino acids**. They are the major structural materials in animal systems. All naturally occurring proteins are formed from 22 amino acids, although only 20 are common. The amino acids are linked by **peptide bonds**. A **polypeptide** is a polymer formed by linking many amino acids by peptide bonds.

Amino acids are chiral substances. Usually only one of the enantiomers is found to be biologically active. Protein structure is determined by the sequence of amino acids in the chain (its **primary structure**), the coiling or stretching of the chain (its **secondary structure**), and the overall shape of the complete molecule (its **tertiary structure**). Two important secondary structures are the **α -helix** and the **β sheet**. The process by which a protein assumes its biologically active tertiary structure is called **folding**. Sometimes several proteins aggregate together to form a **quaternary structure**.

SECTIONS 24.8 AND 24.9 **Carbohydrates**, which are polyhydroxy aldehydes and ketones, are the major structural constituents of plants and are a source of energy in both plants and animals. **Glucose** is the most common **monosaccharide**, or simple sugar. Two monosaccharides can be linked together by means of a condensation reaction to form a **disaccharide**. **Polysaccharides** are complex carbohydrates

made up of many monosaccharide units joined together. The three most important polysaccharides are **starch**, which is found in plants; **glycogen**, which is found in mammals; and **cellulose**, which is also found in plants.

Lipids are compounds derived from glycerol and fatty acids and include fats and **phospholipids**. Fatty acids can be *saturated*, *unsaturated*, *cis*, or *trans* depending on their chemical formulas and structures.

SECTION 24.10 Nucleic acids are biopolymers that carry the genetic information necessary for cell reproduction; they also control cell

development through control of protein synthesis. The building blocks of these biopolymers are **nucleotides**. There are two types of nucleic acids, the **ribonucleic acids (RNA)** and the **deoxyribonucleic acids (DNA)**. These substances consist of a polymeric backbone of alternating phosphate and ribose or deoxyribose sugar groups with organic bases attached to the sugar molecules. The DNA polymer is a double-stranded helix (**double helix**) held together by hydrogen bonding between matching organic bases situated across from one another on the two strands. The hydrogen bonding between specific base pairs is the key to gene replication and protein synthesis.

KEY SKILLS

- Distinguish among alkanes, alkenes, alkynes, and aromatic hydrocarbons. (Section 24.2)
- Draw hydrocarbon structures based on their names and name hydrocarbons based on their structures. (Sections 24.2 and 24.3)
- Distinguish between addition reactions and substitution reactions. (Section 24.3)
- Know the structures of the functional groups: alkene, alkyne, alcohol, carbonyl, ether, aldehyde, ketone, carboxylic acid, amine, amide. (Section 24.4)
- Understand what makes a compound chiral and be able to recognize a chiral substance. (Section 24.5)
- Recognize the amino acids and understand how they form peptides and proteins via amide bond formation. (Section 24.7)
- Understand the differences among the primary, secondary, tertiary, and quaternary structures of proteins. (Section 24.7)
- Be able to explain the difference between α -helix and β -sheet peptide and protein structures. (Section 24.7)
- Understand the distinction between starch and cellulose structures. (Section 24.8)
- Classify molecules as saccharides or lipids based on their structures. (Sections 24.8 and 24.9)
- Understand the difference between a saturated and unsaturated fat. (Section 24.9)
- Understand the structure of nucleic acids and the role played by complementary bases in DNA replication. (Section 24.10)

EXERCISES

VISUALIZING CONCEPTS

24.1 All the structures shown here have the molecular formula C_8H_{18} . Which structures are the same molecule? (*Hint*: One way to answer this question is to determine the chemical name for each structure.) [Section 24.2]

24.2 Which of these molecules is unsaturated? [Section 24.3]

24.3 Which of these molecules most readily undergoes an addition reaction? [Section 24.3]

24.4 Which of these compounds would you expect to have the highest boiling point? Explain. [Section 24.4]

24.5 Which of these compounds can be a member of an isomer pair? In each case where isomerism is possible, identify the type or types of isomerism. [Sections 24.2, 24.4]

(a)

(b)

(c)

(d)

24.6 From examination of the molecular models i-v, choose the substance that (a) can be hydrolyzed to form a solution containing glucose, (b) is capable of forming a zwitterion, (c) is one of the four bases present in DNA, (d) reacts with an acid to form an ester, (e) is a lipid. [Sections 24.6–24.10]

INTRODUCTION TO ORGANIC COMPOUNDS; HYDROCARBONS (sections 24.1 and 24.2)

- 24.7 What are the characteristic hybrid orbitals employed by (a) carbon in an alkane, (b) carbon in a double bond in an alkene, (c) carbon in the benzene ring, (d) carbon in a triple bond in an alkyne?
- 24.8 What are the approximate bond angles (a) about carbon in an alkane, (b) about a doubly bonded carbon atom in an alkene, (c) about a triply bonded carbon atom in an alkyne?
- 24.9 Predict the ideal values for the bond angles about each carbon atom in the following molecule. Indicate the hybridization of orbitals for each carbon.

24.10 Identify the carbon atom(s) in the structure shown that has (have) each of the following hybridizations: (a) sp^3 , (b) sp , (c) sp^2 .

- 24.11 Are carbon monoxide or ammonia considered organic molecules? Why or why not?
- 24.12 Organic compounds containing C—O and C—Cl bonds are more reactive than simple alkane hydrocarbons. Considering the comparative values of C—H, C—C, C—O, and C—Cl bond enthalpies (Table 8.4), why is this so?
- 24.13 (a) What is the difference between a straight-chain and branched-chain alkane? (b) What is the difference between an alkane and an alkyl group?
- 24.14 What structural features help us identify a compound as (a) an alkane, (b) a cycloalkane, (c) an alkene, (d) an alkyne, (e) a saturated hydrocarbon, (f) an aromatic hydrocarbon?
- 24.15 Give the name or condensed structural formula, as appropriate:

- (c) 2-methylheptane
 (d) 4-ethyl-2,3-dimethyloctane
 (e) 1,2-dimethylcyclohexane

24.16 Give the name or condensed structural formula, as appropriate:

- (c) 2,5,6-trimethylnonane
 (d) 3-propyl-4,5-methyldecane
 (e) 1-ethyl-3-methylcyclohexane

24.17 Give the name or condensed structural formula, as appropriate:

- (b) 2,2-dimethylpentane
 (c) 4-ethyl-1,1-dimethylcyclohexane
 (d) $(\text{CH}_3)_2\text{CHCH}_2\text{CH}_2\text{C}(\text{CH}_3)_3$
 (e) $\text{CH}_3\text{CH}_2\text{CH}(\text{C}_2\text{H}_5)\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$

24.18 Give the name or condensed structural formula, as appropriate:

- (a) 3-phenylpentane
 (b) 2,3-dimethylhexane
 (c) 2-ethyl-2-methylheptane
 (d) $\text{CH}_3\text{CH}_2\text{CH}(\text{CH}_3)\text{CH}_2\text{CH}(\text{CH}_3)_2$

24.19 What is the octane number of a mixture that is 35% heptane and 65% isooctane?

24.20 Describe two ways in which the octane number of a gasoline consisting of alkanes can be increased.

ALKENES, ALKYNES, AND AROMATIC HYDROCARBONS (section 24.3)

24.21 (a) Why are alkanes said to be saturated? (b) Is C_4H_6 a saturated hydrocarbon? Why or why not?

24.22 (a) Is the compound $\text{CH}_3\text{CH}=\text{CH}_2$ saturated or unsaturated? Explain. (b) What is wrong with the formula $\text{CH}_3\text{CH}_2\text{CH}=\text{CH}_3$?

24.23 Give the molecular formula of a hydrocarbon containing five carbon atoms that is (a) an alkane, (b) a cycloalkane, (c) an alkene, (d) an alkyne. Which are saturated and which are unsaturated hydrocarbons?

24.24 Give the molecular formula of a cyclic alkane, a cyclic alkene, a linear alkyne, and an aromatic hydrocarbon that in each case contains six carbon atoms. Which are saturated and which are unsaturated hydrocarbons?

24.25 Eneidyne are a class of compounds that include some antibiotic drugs. Draw the structure of an "enediynes" fragment that contains six carbons in a row. (*Hint: di* means "two.")

24.26 Give the general formula for any cyclic alkene, that is, a cyclic hydrocarbon with one double bond.

24.27 Write the condensed structural formulas for as many alkenes and alkynes as you can think of that have the molecular formula C_6H_{10} .

24.28 Draw all the possible noncyclic structural isomers of C_5H_{10} . Name each compound.

24.29 Name or write the condensed structural formula for the following compounds:

- (a) *trans*-2-pentene
 (b) 2,5-dimethyl-4-octene

24.30 Name or write the condensed structural formula for the following compounds:

- (a) 4-methyl-2-pentene
 (b) *cis*-2,5-dimethyl-3-hexene
 (c) ortho-dimethylbenzene
 (d) $\text{HC}\equiv\text{CCH}_2\text{CH}_3$
 (e) *trans*- $\text{CH}_3\text{CH}=\text{CHCH}_2\text{CH}_2\text{CH}_3$

24.31 Why is geometric isomerism possible for alkenes but not for alkanes and alkynes?

24.32 Draw all structural and geometric isomers of butene and name them.

24.33 Indicate whether each of the following molecules is capable of geometrical (*cis-trans*) isomerism. For those that are, draw the structures: (a) 1,1-dichloro-1-butene, (b) 2,4-dichloro-2-butene, (c) 1,4-dichlorobenzene, (d) 4,5-dimethyl-2-pentyne.

24.34 Draw the three distinct geometric isomers of 2,4-hexadiene.

24.35 (a) What is the difference between a substitution reaction and an addition reaction? Which one is commonly observed with alkenes and which one with aromatic hydrocarbons? (b) Using condensed structural formulas, write the balanced equation for the addition reaction of 2-pentene with Br_2 and name the

resulting compound. (c) Write a balanced chemical equation for the substitution reaction of Cl_2 with benzene to make *para*-dichlorobenzene in the presence of FeCl_3 as a catalyst.

24.36 Using condensed structural formulas, write a balanced chemical equation for each of the following reactions: (a) hydrogenation of cyclohexene; (b) addition of H_2O to *trans*-2-pentene using H_2SO_4 as a catalyst (two products); (c) reaction of 2-chloropropane with benzene in the presence of AlCl_3 .

24.37 (a) When cyclopropane is treated with HI, 1-iodopropane is formed. A similar type of reaction does not occur with cyclopentane or cyclohexane. How do you account for the reactivity of cyclopropane? (b) Suggest a method of preparing ethylbenzene, starting with benzene and ethylene as the only organic reagents.

24.38 (a) One test for the presence of an alkene is to add a small amount of bromine, a red-brown liquid, and look for the disappearance of the red-brown color. This test does not work for detecting the presence of an aromatic hydrocarbon. Explain. (b) Write a series of reactions leading to *para*-bromoethylben-

zene, beginning with benzene and using other reagents as needed. What isomeric side products might also be formed?

24.39 The rate law for addition of Br_2 to an alkene is first order in Br_2 and first order in the alkene. Does this fact prove that the mechanism of addition of Br_2 to an alkene proceeds in the same manner as for addition of HBr ? Explain.

24.40 Describe the intermediate that is thought to form in the addition of a hydrogen halide to an alkene, using cyclohexene as the alkene in your description.

24.41 The molar heat of combustion of gaseous cyclopropane is -2089 kJ/mol; that for gaseous cyclopentane is -3317 kJ/mol. Calculate the heat of combustion per CH_2 group in the two cases, and account for the difference.

24.42 The heat of combustion of decahydronaphthalene ($\text{C}_{10}\text{H}_{18}$) is -6286 kJ/mol. The heat of combustion of naphthalene (C_{10}H_8) is -5157 kJ/mol. [In both cases $\text{CO}_2(\text{g})$ and $\text{H}_2\text{O}(\text{l})$ are the products.] Using these data and data in Appendix C, calculate the heat of hydrogenation of naphthalene. Does this value provide any evidence for aromatic character in naphthalene?

FUNCTIONAL GROUPS AND CHIRALITY (sections 24.4 and 24.5)

24.43 Identify the functional groups in each of the following compounds:

24.44 Identify the functional groups in each of the following compounds:

24.45 Give the structural formula for (a) an aldehyde that is an isomer of acetone, (b) an ether that is an isomer of 1-propanol.

24.46 (a) Give the empirical formula and structural formula for a cyclic ether containing four carbon atoms in the ring. (b) Write the structural formula for a straight-chain compound that is a structural isomer of your answer to part (a).

24.47 The IUPAC name for a carboxylic acid is based on the name of the hydrocarbon with the same number of carbon atoms. The ending *-oic* is appended, as in ethanoic acid, which is the IUPAC name for acetic acid. Draw the structure of the following acids: (a) methanoic acid, (b) pentanoic acid, (c) 2-chloro-3-methyldecanoic acid.

24.48 Aldehydes and ketones can be named in a systematic way by counting the number of carbon atoms (including the carbonyl carbon) that they contain. The name of the aldehyde or ketone is based on the hydrocarbon with the same number of carbon atoms. The ending *-al* for aldehyde or *-one* for ketone is added as appropriate. Draw the structural formulas for the following aldehydes or ketones: (a) propanal, (b) 2-pentanone, (c) 3-methyl-2-butanone, (d) 2-methylbutanal.

24.49 Draw the condensed structure of the compounds formed by condensation reactions between (a) benzoic acid and ethanol, (b) ethanoic acid and methylamine, (c) acetic acid and phenol. Name the compound in each case.

24.50 Draw the condensed structures of the compounds formed from (a) butanoic acid and methanol, (b) benzoic acid and 2-propanol, (c) propanoic acid and dimethylamine. Name the compound in each case.

24.51 Write a balanced chemical equation using condensed structural formulas for the saponification (base hydrolysis) of (a) methyl propionate, (b) phenyl acetate.

24.52 Write a balanced chemical equation using condensed structural formulas for (a) the formation of butyl propionate from the appropriate acid and alcohol, (b) the saponification (base hydrolysis) of methyl benzoate.

24.53 Would you expect pure acetic acid to be a strongly hydrogen-bonded substance? How do the melting and boiling points of the substance (16.7°C and 118°C) support your answer?

- 24.54 Acetic anhydride is formed from acetic acid in a condensation reaction that involves the removal of a molecule of water from between two acetic acid molecules. Write the chemical equation for this process, and show the structure of acetic anhydride.
- 24.55 Write the condensed structural formula for each of the following compounds: (a) 2-pentanol, (b) 1,2-propanediol, (c) ethyl acetate, (d) diphenyl ketone, (e) methyl ethyl ether.

- 24.56 Write the condensed structural formula for each of the following compounds: (a) 2-ethyl-1-hexanol, (b) methyl phenyl ketone, (c) *para*-bromobenzoic acid, (d) ethyl butyl ether, (e) *N,N*-dimethylbenzamide.
- 24.57 Draw the structure for 2-bromo-2-chloro-3-methylpentane, and indicate any chiral carbons in the molecule.
- 24.58 Does 3-chloro-3-methylhexane have optical isomers? Why or why not?

PROTEINS (section 24.7)

- 24.59 (a) What is an α -amino acid? (b) How do amino acids react to form proteins? (c) Draw the bond that links amino acids together in proteins. What is this called?
- 24.60 What properties of the side chains (R groups) of amino acids are important in affecting the amino acids' overall biochemical behavior? Give examples to illustrate your reply.
- 24.61 Draw the two possible dipeptides formed by condensation reactions between leucine and tryptophan.
- 24.62 Write a chemical equation for the formation of methionyl glycine from the constituent amino acids.
- 24.63 (a) Draw the condensed structure of the tripeptide Gly-Gly-His. (b) How many different tripeptides can be made from the amino acids glycine and histidine? Give the abbreviations for each of these tripeptides, using the three-letter and one-letter codes for the amino acids.
- 24.64 (a) What amino acids would be obtained by hydrolysis of the following tripeptide?

(b) How many different tripeptides can be made from glycine, serine, and glutamic acid? Give the abbreviation for each of these tripeptides, using the three-letter codes and one-letter codes for the amino acids.

- 24.65 (a) Describe the primary, secondary, and tertiary structures of proteins. (b) *Quaternary structures* of proteins arise if two or more smaller polypeptides or proteins associate with each other to make an overall much larger protein structure. The association is due to the same hydrogen bonding, electrostatic, and dispersion forces we have seen before. Hemoglobin, the protein used to transport oxygen molecules in our blood, is an example of a protein that has quaternary structure. Hemoglobin is a tetramer; it is made of four smaller polypeptides, two "alphas" and two "betas." (These names do not imply anything about the number of alpha-helices or beta sheets in the individual polypeptides.) What kind of experiments would provide sound evidence that hemoglobin exists as a tetramer and not as one enormous polypeptide chain? You may need to look into the chemical literature to discover techniques that chemists and biochemists use to make these decisions.
- 24.66 What is the difference between the α -helix and β -sheet secondary structures in proteins?

CARBOHYDRATES AND LIPIDS (sections 24.8 and 24.9)

- 24.67 In your own words, define the following terms: (a) carbohydrate, (b) monosaccharide, (c) disaccharide, (d) polysaccharide.
- 24.68 What is the difference between α -glucose and β -glucose? Show the condensation of two glucose molecules to form a disaccharide with an α linkage; with a β linkage.
- 24.69 What is the empirical formula of cellulose? What is the unit that forms the basis of the cellulose polymer? What form of linkage joins these monomeric units?
- 24.70 What is the empirical formula of glycogen? What is the unit that forms the basis of the glycogen polymer? What form of linkage joins these monomeric units?
- 24.71 The structural formula for the linear form of D-mannose is

- (a) How many chiral carbons are present in the molecule? (b) Draw the structure of the six-member-ring form of this sugar.
- 24.72 The structural formula for the linear form of galactose is

- (a) How many chiral carbons are present in the molecule? (b) Draw the structure of the six-member-ring form of this sugar.
- 24.73 Describe the chemical structures of lipids and phospholipids. Why can phospholipids form a bilayer in water?
- 24.74 Using data from Table 8.4 on bond enthalpies, show that the more C—H bonds a molecule has compared to C—O and O—H bonds, the more energy it can store.

NUCLEIC ACIDS (section 24.10)

- 24.75** Adenine and guanine are members of a class of molecules known as *purines*; they have two rings in their structure. Thymine and cytosine, on the other hand, are *pyrimidines*, and have only one ring in their structure. Predict which have larger dispersion forces in aqueous solution, the purines or the pyrimidines.
- 24.76** A nucleoside consists of an organic base of the kind shown in Section 24.10, bound to ribose or deoxyribose. Draw the structure for deoxyguanosine, formed from guanine and deoxyribose.
- 24.77** Just as the amino acids in a protein are listed in the order from the amine end to the carboxylic acid end (the *protein sequence*), the bases in nucleic acids are listed in the order 5' to 3', where the numbers refer to the position of the carbons in the sugars (shown here for deoxyribose):

The base is attached to the sugar at the 1' carbon. The 5' end of a DNA sequence is a phosphate of an OH group, and the 3' end of a DNA sequence is the OH group. What is the DNA sequence for the molecule shown here?

- 24.78** When samples of double-stranded DNA are analyzed, the quantity of adenine present equals that of thymine. Similarly, the quantity of guanine equals that of cytosine. Explain the significance of these observations.
- 24.79** Imagine a single DNA strand containing a section with the following base sequence: 5'-GCATTGGC-3'. What is the base sequence of the complementary strand? (The two strands of DNA will come together in an *antiparallel* fashion; that is, 5'-TAG-3' will bind to 3'-ATC-5'.)
- 24.80** Explain the chemical differences between DNA and RNA.

ADDITIONAL EXERCISES

- 24.81** Draw the condensed structural formulas for two different molecules with the formula C_3H_4O .
- 24.82** How many structural isomers are there for a five-member straight carbon chain with one double bond? For a six-member straight carbon chain with two double bonds?
- 24.83** Draw the condensed structural formulas for the *cis* and *trans* isomers of 2-pentene. Can cyclopentene exhibit *cis-trans* isomerism? Explain.
- 24.84** If a molecule is an “ene-one,” what functional groups must it have?
- 24.85** Write the structural formulas for as many alcohols as you can think of that have empirical formula C_3H_6O .
- 24.86** Identify each of the functional groups in these molecules:

(Responsible for the odor of cucumbers)

(Quinine — an antimalarial drug)

(Indigo — a blue dye)

(Acetaminophen — aka Tylenol)

- 24.87** Write a condensed structural formula for each of the following: (a) an acid with the formula $C_4H_8O_2$, (b) a cyclic ketone with the formula C_5H_8O , (c) a dihydroxy compound with the formula $C_3H_8O_2$, (d) a cyclic ester with the formula $C_5H_8O_2$.
- 24.88** Although carboxylic acids and alcohols both contain an —OH group, one is acidic in water and the other is not. Explain the difference.
- [24.89]** Indole smells terrible in high concentrations but has a pleasant floral-like odor when highly diluted. Its structure is

The molecule is planar, and the nitrogen is a very weak base, with $K_b = 2 \times 10^{-12}$. Explain how this information indicates that the indole molecule is aromatic.

24.90 Locate the chiral carbon atoms, if any, in each molecule:

INTEGRATIVE EXERCISES

24.95 Explain why the boiling point of ethanol (78 °C) is much higher than that of its isomer, dimethyl ether (−25 °C), and why the boiling point of CH_2F_2 (−52 °C) is far above that of CH_4 (−128 °C).

[24.96] An unknown organic compound is found on elemental analysis to contain 68.1% carbon, 13.7% hydrogen, and 18.2% oxygen by mass. It is slightly soluble in water. Upon careful oxidation it is converted into a compound that behaves chemically like a ketone and contains 69.7% carbon, 11.7% hydrogen, and 18.6% oxygen by mass. Indicate two or more reasonable structures for the unknown.

24.97 An organic compound is analyzed and found to contain 66.7% carbon, 11.2% hydrogen, and 22.1% oxygen by mass. The compound boils at 79.6 °C. At 100 °C and 0.970 atm, the vapor has a density of 2.28 g/L. The compound has a carbonyl group and cannot be oxidized to a carboxylic acid. Suggest a structure for the compound.

[24.98] An unknown substance is found to contain only carbon and hydrogen. It is a liquid that boils at 49 °C at 1 atm pressure. Upon analysis it is found to contain 85.7% carbon and 14.3% hydrogen by mass. At 100 °C and 735 torr, the vapor of this unknown has a density of 2.21 g/L. When it is dissolved in hexane solution and bromine water is added, no reaction occurs. What is the identity of the unknown compound?

24.99 The standard free energy of formation of solid glycine is −369 kJ/mol, whereas that of solid glycyglycine is −488 kJ/mol. What is ΔG° for the condensation of glycine to form glycyglycine?

24.100 A typical amino acid with one amino group and one carboxylic acid group, such as serine (Figure 24.18), can exist in water in several ionic forms. (a) Suggest the forms of the amino acid at low pH and at high pH. (b) Amino acids generally have two $\text{p}K_a$ values, one in the range of 2 to 3 and the other in the range of 9 to 10. Serine, for example, has $\text{p}K_a$ values of 2.19 and 9.21. Using species such as acetic acid and ammonia as models, suggest the origin of the two $\text{p}K_a$ values. (c) Glutamic acid is an amino acid that has three $\text{p}K_a$'s: 2.10, 4.07, and 9.47. Draw the structure of glutamic acid, and assign each $\text{p}K_a$ to the appropriate part of the molecule.

24.91 Which of the following peptides have a net positive charge at pH 7? (a) Gly-Ser-Lys, (b) Pro-Leu-Ile, (c) Phe-Tyr-Asp.

24.92 Glutathione is a tripeptide found in most living cells. Partial hydrolysis yields Cys-Gly and Glu-Cys. What structures are possible for glutathione?

24.93 Monosaccharides can be categorized in terms of the number of carbon atoms (pentoses have five carbons and hexoses have six carbons) and according to whether they contain an aldehyde (*aldo-* prefix, as in aldopentose) or ketone group (*keto-* prefix, as in ketopentose). Classify glucose and fructose in this way.

24.94 Can a DNA strand bind to a complementary RNA strand? Explain.

[24.101] The protein ribonuclease A in its native, or most stable, form is folded into a compact globular shape:

Native ribonuclease A

(a) Does the native form have a lower or higher free energy than the denatured form, in which the protein is an extended chain? (b) What is the sign of the entropy change in going from the denatured to the folded form? (c) In the native form, the molecule has four —S—S— bonds that bridge parts of the chain. What effect do you predict these four linkages to have on the free energy and entropy of the native form relative to the free energy and entropy of a hypothetical folded structure that does not have any —S—S— linkages? Explain. (d) A gentle reducing agent converts the four —S—S— linkages in ribonuclease A to eight —S—H bonds. What effect do you predict this conversion to have on the tertiary structure and entropy of the protein? (e) Which amino acid must be present for —SH bonds to exist in ribonuclease A?

24.102 The monoanion of adenosine monophosphate (AMP) is an intermediate in phosphate metabolism:

where A = adenosine. If the $\text{p}K_a$ for this anion is 7.21, what is the ratio of $[\text{AMP}-\text{OH}^-]$ to $[\text{AMP}-\text{O}^{2-}]$ in blood at pH 7.4?

MATHEMATICAL OPERATIONS

A.1 EXPONENTIAL NOTATION

The numbers used in chemistry are often either extremely large or extremely small. Such numbers are conveniently expressed in the form

$$N \times 10^n$$

where N is a number between 1 and 10, and n is the exponent. Some examples of this *exponential notation*, which is also called *scientific notation*, follow.

1,200,000 is 1.2×10^6 (read “one point two times ten to the sixth power”)

0.000604 is 6.04×10^{-4} (read “six point zero four times ten to the negative fourth power”)

A positive exponent, as in the first example, tells us how many times a number must be multiplied by 10 to give the long form of the number:

$$\begin{aligned} 1.2 \times 10^6 &= 1.2 \times 10 \times 10 \times 10 \times 10 \times 10 \times 10 \quad (\text{six tens}) \\ &= 1,200,000 \end{aligned}$$

It is also convenient to think of the *positive exponent* as the number of places the decimal point must be moved to the *left* to obtain a number greater than 1 and less than 10. For example, if we begin with 3450 and move the decimal point three places to the left, we end up with 3.45×10^3 .

In a related fashion, a negative exponent tells us how many times we must divide a number by 10 to give the long form of the number.

$$6.04 \times 10^{-4} = \frac{6.04}{10 \times 10 \times 10 \times 10} = 0.000604$$

It is convenient to think of the *negative exponent* as the number of places the decimal point must be moved to the *right* to obtain a number greater than 1 but less than 10. For example, if we begin with 0.0048 and move the decimal point three places to the right, we end up with 4.8×10^{-3} .

In the system of exponential notation, with each shift of the decimal point one place to the right, the exponent *decreases* by 1:

$$4.8 \times 10^{-3} = 48 \times 10^{-4}$$

Similarly, with each shift of the decimal point one place to the left, the exponent *increases* by 1:

$$4.8 \times 10^{-3} = 0.48 \times 10^{-2}$$

Many scientific calculators have a key labeled EXP or EE, which is used to enter numbers in exponential notation. To enter the number 5.8×10^3 on such a calculator, the key sequence is

$$\boxed{5} \boxed{\cdot} \boxed{8} \boxed{\text{EXP}} \text{ (or } \boxed{\text{EE}} \text{) } \boxed{3}$$

On some calculators the display will show 5.8, then a space, followed by 03, the exponent. On other calculators, a small 10 is shown with an exponent 3.

To enter a negative exponent, use the key labeled $+/-$. For example, to enter the number 8.6×10^{-5} , the key sequence is

$$\boxed{8} \boxed{\cdot} \boxed{6} \boxed{\text{EXP}} \boxed{+/-} \boxed{5}$$

When entering a number in exponential notation, do not key in the 10 if you use the EXP or EE button.

In working with exponents, it is important to recall that $10^0 = 1$. The following rules are useful for carrying exponents through calculations.

- 1. Addition and Subtraction** In order to add or subtract numbers expressed in exponential notation, the powers of 10 must be the same.

$$\begin{aligned} (5.22 \times 10^4) + (3.21 \times 10^2) &= (522 \times 10^2) + (3.21 \times 10^2) \\ &= 525 \times 10^2 \quad (3 \text{ significant figures}) \\ &= 5.25 \times 10^4 \end{aligned}$$

$$\begin{aligned} (6.25 \times 10^{-2}) - (5.77 \times 10^{-3}) &= (6.25 \times 10^{-2}) - (0.577 \times 10^{-2}) \\ &= 5.67 \times 10^{-2} \quad (3 \text{ significant figures}) \end{aligned}$$

When you use a calculator to add or subtract, you need not be concerned with having numbers with the same exponents because the calculator automatically takes care of this matter.

- 2. Multiplication and Division** When numbers expressed in exponential notation are multiplied, the exponents are added; when numbers expressed in exponential notation are divided, the exponent of the denominator is subtracted from the exponent of the numerator.

$$\begin{aligned} (5.4 \times 10^2)(2.1 \times 10^3) &= (5.4)(2.1) \times 10^{2+3} \\ &= 11 \times 10^5 \\ &= 1.1 \times 10^6 \end{aligned}$$

$$(1.2 \times 10^5)(3.22 \times 10^{-3}) = (1.2)(3.22) \times 10^{5+(-3)} = 3.9 \times 10^2$$

$$\frac{3.2 \times 10^5}{6.5 \times 10^2} = \frac{3.2}{6.5} \times 10^{5-2} = 0.49 \times 10^3 = 4.9 \times 10^2$$

$$\frac{5.7 \times 10^7}{8.5 \times 10^{-2}} = \frac{5.7}{8.5} \times 10^{7-(-2)} = 0.67 \times 10^9 = 6.7 \times 10^8$$

- 3. Powers and Roots** When numbers expressed in exponential notation are raised to a power, the exponents are multiplied by the power. When the roots of numbers expressed in exponential notation are taken, the exponents are divided by the root.

$$\begin{aligned} (1.2 \times 10^5)^3 &= (1.2)^3 \times 10^{5 \times 3} \\ &= 1.7 \times 10^{15} \\ \sqrt[3]{2.5 \times 10^6} &= \sqrt[3]{2.5} \times 10^{6/3} \\ &= 1.3 \times 10^2 \end{aligned}$$

Scientific calculators usually have keys labeled x^2 and \sqrt{x} for squaring and taking the square root of a number, respectively. To take higher powers or roots, many calculators have y^x and $\sqrt[y]{y}$ (or INV y^x) keys. For example, to perform the operation $\sqrt[3]{7.5} \times 10^{-4}$ on such a calculator, you would key in 7.5×10^{-4} , press the $\sqrt[y]{y}$ key (or the INV and then the y^x keys), enter the root, 3, and finally press = . The result is 9.1×10^{-2} .

SAMPLE EXERCISE 1 Using Exponential Notation

Perform each of the following operations, using your calculator where possible:

(a) Write the number 0.0054 in standard exponential notation.

(b) $(5.0 \times 10^{-2}) + (4.7 \times 10^{-3})$

(c) $(5.98 \times 10^{12})(2.77 \times 10^{-5})$

(d) $\sqrt[4]{1.75 \times 10^{-12}}$

SOLUTION

(a) Because we move the decimal point three places to the right to convert 0.0054 to 5.4, the exponent is -3 :

$$5.4 \times 10^{-3}$$

Scientific calculators are generally able to convert numbers to exponential notation using one or two keystrokes; frequently “SCI” for “scientific notation” will convert a number into exponential notation. Consult your instruction manual to see how this operation is accomplished on your calculator.

(b) To add these numbers longhand, we must convert them to the same exponent.

$$(5.0 \times 10^{-2}) + (0.47 \times 10^{-2}) = (5.0 + 0.47) \times 10^{-2} = 5.5 \times 10^{-2}$$

(Note that the result has only two significant figures.) To perform this operation on a calculator, we enter the first number, strike the $+$ key, then enter the second number and strike the $=$ key.

(c) Performing this operation longhand, we have

$$(5.98 \times 2.77) \times 10^{12-5} = 16.6 \times 10^7 = 1.66 \times 10^8$$

On a scientific calculator, we enter 5.98×10^{12} , press the \times key, enter 2.77×10^{-5} , and press the $=$ key.

(d) To perform this operation on a calculator, we enter the number, press the $\sqrt[4]{y}$ key (or the INV and y^x keys), enter 4, and press the $=$ key. The result is 1.15×10^{-3} .

PRACTICE EXERCISE

Perform the following operations:

(a) Write 67,000 in exponential notation, showing two significant figures.

(b) $(3.378 \times 10^{-3}) - (4.97 \times 10^{-5})$

(c) $(1.84 \times 10^{15})(7.45 \times 10^{-2})$

(d) $(6.67 \times 10^{-8})^3$

Answers: (a) 6.7×10^4 , (b) 3.328×10^{-3} , (c) 2.47×10^{16} , (d) 2.97×10^{-22}

A.2 LOGARITHMS**Common Logarithms**

The common, or base-10, logarithm (abbreviated log) of any number is the power to which 10 must be raised to equal the number. For example, the common logarithm of 1000 (written $\log 1000$) is 3 because raising 10 to the third power gives 1000.

$$10^3 = 1000, \text{ therefore, } \log 1000 = 3$$

Further examples are

$$\log 10^5 = 5$$

$$\log 1 = 0 \quad \text{Remember that } 10^0 = 1$$

$$\log 10^{-2} = -2$$

In these examples the common logarithm can be obtained by inspection. However, it is not possible to obtain the logarithm of a number such as 31.25 by inspection. The logarithm of 31.25 is the number x that satisfies the following relationship:

$$10^x = 31.25$$

Most electronic calculators have a key labeled LOG that can be used to obtain logarithms. For example, on many calculators we obtain the value of $\log 31.25$ by entering 31.25 and pressing the LOG key. We obtain the following result:

$$\log 31.25 = 1.4949$$

Notice that 31.25 is greater than 10 (10^1) and less than 100 (10^2). The value for $\log 31.25$ is accordingly between $\log 10$ and $\log 100$, that is, between 1 and 2.

Significant Figures and Common Logarithms

For the common logarithm of a measured quantity, the number of digits after the decimal point equals the number of significant figures in the original number. For example, if 23.5 is a measured quantity (three significant figures), then $\log 23.5 = 1.371$ (three significant figures after the decimal point).

Antilogarithms

The process of determining the number that corresponds to a certain logarithm is known as obtaining an *antilogarithm*. It is the reverse of taking a logarithm. For example, we saw previously that $\log 23.5 = 1.371$. This means that the antilogarithm of 1.371 equals 23.5.

$$\begin{aligned}\log 23.5 &= 1.371 \\ \text{antilog } 1.371 &= 23.5\end{aligned}$$

The process of taking the antilog of a number is the same as raising 10 to a power equal to that number.

$$\text{antilog } 1.371 = 10^{1.371} = 23.5$$

Many calculators have a key labeled 10^x that allows you to obtain antilogs directly. On others, it will be necessary to press a key labeled INV (for *inverse*), followed by the LOG key.

Natural Logarithms

Logarithms based on the number e are called natural, or base e , logarithms (abbreviated \ln). The natural log of a number is the power to which e (which has the value 2.71828...) must be raised to equal the number. For example, the natural log of 10 equals 2.303.

$$e^{2.303} = 10, \text{ therefore } \ln 10 = 2.303$$

Your calculator probably has a key labeled LN that allows you to obtain natural logarithms. For example, to obtain the natural log of 46.8, you enter 46.8 and press the LN key.

$$\ln 46.8 = 3.846$$

The natural antilog of a number is e raised to a power equal to that number. If your calculator can calculate natural logs, it will also be able to calculate natural antilogs. On some calculators there is a key labeled e^x that allows you to calculate natural antilogs directly; on others, it will be necessary to first press the INV key followed by the LN key. For example, the natural antilog of 1.679 is given by

$$\text{Natural antilog } 1.679 = e^{1.679} = 5.36$$

The relation between common and natural logarithms is as follows:

$$\ln a = 2.303 \log a$$

Notice that the factor relating the two, 2.303, is the natural log of 10, which we calculated earlier.

Mathematical Operations Using Logarithms

Because logarithms are exponents, mathematical operations involving logarithms follow the rules for the use of exponents. For example, the product of z^a and z^b (where z is any number) is given by

$$z^a \cdot z^b = z^{(a+b)}$$

Similarly, the logarithm (either common or natural) of a product equals the *sum* of the logs of the individual numbers.

$$\log ab = \log a + \log b \quad \ln ab = \ln a + \ln b$$

For the log of a quotient,

$$\log(a/b) = \log a - \log b \quad \ln(a/b) = \ln a - \ln b$$

Using the properties of exponents, we can also derive the rules for the logarithm of a number raised to a certain power.

$$\begin{aligned} \log a^n &= n \log a & \ln a^n &= n \ln a \\ \log a^{1/n} &= (1/n) \log a & \ln a^{1/n} &= (1/n) \ln a \end{aligned}$$

pH Problems

One of the most frequent uses for common logarithms in general chemistry is in working pH problems. The pH is defined as $-\log[\text{H}^+]$, where $[\text{H}^+]$ is the hydrogen ion concentration of a solution. ∞ (Section 16.4) The following sample exercise illustrates this application.

SAMPLE EXERCISE 2 Using Logarithms

- (a) What is the pH of a solution whose hydrogen ion concentration is 0.015 M?
 (b) If the pH of a solution is 3.80, what is its hydrogen ion concentration?

SOLUTION

1. We are given the value of $[\text{H}^+]$. We use the LOG key of our calculator to calculate the value of $\log[\text{H}^+]$. The pH is obtained by changing the sign of the value obtained. (Be sure to change the sign *after* taking the logarithm.)

$$\begin{aligned} [\text{H}^+] &= 0.015 \\ \log[\text{H}^+] &= -1.82 \quad (2 \text{ significant figures}) \\ \text{pH} &= -(-1.82) = 1.82 \end{aligned}$$

2. To obtain the hydrogen ion concentration when given the pH, we must take the antilog of $-\text{pH}$.

$$\begin{aligned} \text{pH} &= -\log[\text{H}^+] = 3.80 \\ \log[\text{H}^+] &= -3.80 \\ [\text{H}^+] &= \text{antilog}(-3.80) = 10^{-3.80} = 1.6 \times 10^{-4} \text{ M} \end{aligned}$$

PRACTICE EXERCISE

Perform the following operations: (a) $\log(2.5 \times 10^{-5})$, (b) $\ln 32.7$, (c) $\text{antilog } -3.47$, (d) $e^{-1.89}$.
Answers: (a) -4.60 , (b) 3.487 , (c) 3.4×10^{-4} , (d) 1.5×10^{-1}

A.3 QUADRATIC EQUATIONS

An algebraic equation of the form $ax^2 + bx + c = 0$ is called a *quadratic equation*. The two solutions to such an equation are given by the quadratic formula:

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

Many calculators today can calculate the solutions to a quadratic equation with one or two keystrokes. Most of the time, x corresponds to the concentration of a chemical species in solution. Only one of the solutions will be a positive number, and that is the one you should use; a “negative concentration” has no physical meaning.

SAMPLE EXERCISE 3 Using the Quadratic Formula

Find the values of x that satisfy the equation $2x^2 + 4x = 1$.

SOLUTION

To solve the given equation for x , we must first put it in the form

$$ax^2 + bx + c = 0$$

and then use the quadratic formula. If

$$2x^2 + 4x = 1$$

then

$$2x^2 + 4x - 1 = 0$$

Using the quadratic formula, where $a = 2$, $b = 4$, and $c = -1$, we have

$$\begin{aligned} x &= \frac{-4 \pm \sqrt{(4)(4) - 4(2)(-1)}}{2(2)} \\ &= \frac{-4 \pm \sqrt{16 + 8}}{4} = \frac{-4 \pm \sqrt{24}}{4} = \frac{-4 \pm 4.899}{4} \end{aligned}$$

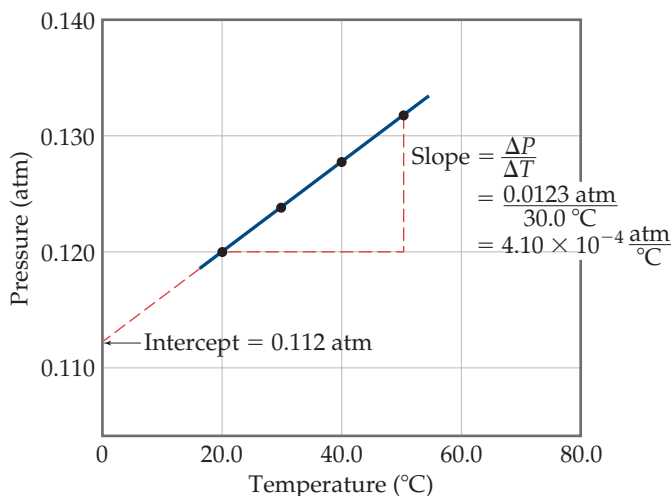

The two solutions are

$$x = \frac{0.899}{4} = 0.225 \quad \text{and} \quad x = \frac{-8.899}{4} = -2.225$$

If this was a problem in which x represented a concentration, we would say $x = 0.225$ (in the appropriate units), since a negative number for concentration has no physical meaning.

TABLE A.1 • Interrelation between Pressure and Temperature

Temperature (°C)	Pressure (atm)
20.0	0.120
30.0	0.124
40.0	0.128
50.0	0.132

▲ FIGURE A.1 A graph of pressure versus temperature yields a straight line for the data.

A.4 GRAPHS

Often the clearest way to represent the interrelationship between two variables is to graph them. Usually, the variable that is being experimentally varied, called the *independent variable*, is shown along the horizontal axis (x -axis). The variable that responds to the change in the independent variable, called the *dependent variable*, is then shown along the vertical axis (y -axis). For example, consider an experiment in which we vary the temperature of an enclosed gas and measure its pressure. The independent variable is temperature, and the dependent variable is pressure. The data shown in ◀ TABLE A.1 can be obtained by means of this experiment. These data are shown graphically in ◀ FIGURE A.1. The relationship between temperature and pressure is linear. The equation for any straight-line graph has the form

$$y = mx + b$$

where m is the slope of the line and b is the intercept with the y -axis. In the case of Figure A.1, we could say that the relationship between temperature and pressure takes the form

$$P = mT + b$$

where P is pressure in atm and T is temperature in °C. As shown in Figure A.1, the slope is 4.10×10^{-4} atm/°C, and the intercept—the point where the line crosses the y -axis—is 0.112 atm. Therefore, the equation for the line is

$$P = \left(4.10 \times 10^{-4} \frac{\text{atm}}{^\circ\text{C}}\right)T + 0.112 \text{ atm}$$

A.5 STANDARD DEVIATION

The standard deviation from the mean, s , is a common method for describing precision in experimentally determined data. We define the standard deviation as

$$s = \sqrt{\frac{\sum_{i=1}^N (x_i - \bar{x})^2}{N - 1}}$$

where N is the number of measurements, \bar{x} is the average (also called the mean) of the measurements, and x_i represents the individual measurements. Electronic calculators with built-in statistical functions can calculate s directly by inputting the individual measurements.

A smaller value of s indicates a higher precision, meaning that the data are more closely clustered around the average. The standard deviation has statistical significance. If a large number of measurements is made, 68% of the measured values is expected to be within one standard deviation of the average, assuming only random errors are associated with the measurements.

SAMPLE EXERCISE 4 Calculating an Average and Standard Deviation

The percent carbon in a sugar is measured four times: 42.01%, 42.28%, 41.79%, and 42.25%. Calculate (a) the average and (b) the standard deviation for these measurements.

SOLUTION

(a) The average is found by adding the quantities and dividing by the number of measurements:

$$\bar{x} = \frac{42.01 + 42.28 + 41.79 + 42.25}{4} = \frac{168.33}{4} = 42.08$$

(b) The standard deviation is found using the preceding equation:

$$s = \sqrt{\frac{\sum_{i=1}^N (x_i - \bar{x})^2}{N - 1}}$$

Let's tabulate the data so the calculation of $\sum_{i=1}^N (x_i - \bar{x})^2$ can be seen clearly.

Percent C	Difference between Measurement and Average, $(x_i - \bar{x})$	Square of Difference, $(x_i - \bar{x})^2$
42.01	$42.01 - 42.08 = -0.07$	$(-0.07)^2 = 0.005$
42.28	$42.28 - 42.08 = 0.20$	$(0.20)^2 = 0.040$
41.79	$41.79 - 42.08 = -0.29$	$(-0.29)^2 = 0.084$
42.25	$42.25 - 42.08 = 0.17$	$(0.17)^2 = 0.029$

The sum of the quantities in the last column is

$$\sum_{i=1}^N (x_i - \bar{x})^2 = 0.005 + 0.040 + 0.084 + 0.029 = 0.16$$

Thus, the standard deviation is

$$s = \sqrt{\frac{\sum_{i=1}^N (x_i - \bar{x})^2}{N - 1}} = \sqrt{\frac{0.16}{4 - 1}} = \sqrt{\frac{0.16}{3}} = \sqrt{0.053} = 0.23$$

Based on these measurements, it would be appropriate to represent the measured percent carbon as 42.08 ± 0.23 .

PROPERTIES OF WATER

Density:	0.99987 g/mL at 0 °C 1.00000 g/mL at 4 °C 0.99707 g/mL at 25 °C 0.95838 g/mL at 100 °C

AQUEOUS EQUILIBRIUM CONSTANTS

TABLE D.1 • Dissociation Constants for Acids at 25 °C

Name	Formula	K_{a1}	K_{a2}	K_{a3}
Acetic acid	CH ₃ COOH (or HC ₂ H ₃ O ₂)	1.8×10^{-5}		
Arsenic acid	H ₃ AsO ₄	5.6×10^{-3}	1.0×10^{-7}	3.0×10^{-12}
Arsenous acid	H ₃ AsO ₃	5.1×10^{-10}		
Ascorbic acid	H ₂ C ₆ H ₆ O ₆	8.0×10^{-5}	1.6×10^{-12}	
Benzoic acid	C ₆ H ₅ COOH (or HC ₇ H ₅ O ₂)	6.3×10^{-5}		
Boric acid	H ₃ BO ₃	5.8×10^{-10}		
Butanoic acid	C ₃ H ₇ COOH (or HC ₄ H ₇ O ₂)	1.5×10^{-5}		
Carbonic acid	H ₂ CO ₃	4.3×10^{-7}	5.6×10^{-11}	
Chloroacetic acid	CH ₂ ClCOOH (or HC ₂ H ₂ O ₂ Cl)	1.4×10^{-3}		
Chlorous acid	HClO ₂	1.1×10^{-2}		
Citric acid	HOCC(OH)(CH ₂ COOH) ₂ (or H ₃ C ₆ H ₅ O ₇)	7.4×10^{-4}	1.7×10^{-5}	4.0×10^{-7}
Cyanic acid	HCNO	3.5×10^{-4}		
Formic acid	HCOOH (or HCHO ₂)	1.8×10^{-4}		
Hydroazoic acid	HN ₃	1.9×10^{-5}		
Hydrocyanic acid	HCN	4.9×10^{-10}		
Hydrofluoric acid	HF	6.8×10^{-4}		
Hydrogen chromate ion	HCrO ₄ ⁻	3.0×10^{-7}		
Hydrogen peroxide	H ₂ O ₂	2.4×10^{-12}		
Hydrogen selenate ion	HSeO ₄ ⁻	2.2×10^{-2}		
Hydrogen sulfide	H ₂ S	9.5×10^{-8}	1×10^{-19}	
Hypobromous acid	HBrO	2.5×10^{-9}		
Hypochlorous acid	HClO	3.0×10^{-8}		
Hypoiodous acid	HIO	2.3×10^{-11}		
Iodic acid	HIO ₃	1.7×10^{-1}		
Lactic acid	CH ₃ CH(OH)COOH (or HC ₃ H ₅ O ₃)	1.4×10^{-4}		
Malonic acid	CH ₂ (COOH) ₂ (or H ₂ C ₃ H ₂ O ₄)	1.5×10^{-3}	2.0×10^{-6}	
Nitrous acid	HNO ₂	4.5×10^{-4}		
Oxalic acid	(COOH) ₂ (or H ₂ C ₂ O ₄)	5.9×10^{-2}	6.4×10^{-5}	
Paraperiodic acid	H ₅ IO ₆	2.8×10^{-2}	5.3×10^{-9}	
Phenol	C ₆ H ₅ OH (or HC ₆ H ₅ O)	1.3×10^{-10}		
Phosphoric acid	H ₃ PO ₄	7.5×10^{-3}	6.2×10^{-8}	4.2×10^{-13}
Propionic acid	C ₂ H ₅ COOH (or HC ₃ H ₅ O ₂)	1.3×10^{-5}		
Pyrophosphoric acid	H ₄ P ₂ O ₇	3.0×10^{-2}	4.4×10^{-3}	2.1×10^{-7}
Selenous acid	H ₂ SeO ₃	2.3×10^{-3}	5.3×10^{-9}	
Sulfuric acid	H ₂ SO ₄	Strong acid	1.2×10^{-2}	
Sulfurous acid	H ₂ SO ₃	1.7×10^{-2}	6.4×10^{-8}	
Tartaric acid	HOOC(CHOH) ₂ COOH (or H ₂ C ₄ H ₄ O ₆)	1.0×10^{-3}		

TABLE D.2 • Dissociation Constants for Bases at 25 °C

Name	Formula	K_b
Ammonia	NH ₃	1.8×10^{-5}
Aniline	C ₆ H ₅ NH ₂	4.3×10^{-10}
Dimethylamine	(CH ₃) ₂ NH	5.4×10^{-4}
Ethylamine	C ₂ H ₅ NH ₂	6.4×10^{-4}
Hydrazine	H ₂ NNH ₂	1.3×10^{-6}
Hydroxylamine	HONH ₂	1.1×10^{-8}
Methylamine	CH ₃ NH ₂	4.4×10^{-4}
Pyridine	C ₅ H ₅ N	1.7×10^{-9}
Trimethylamine	(CH ₃) ₃ N	6.4×10^{-5}

TABLE D.3 • Solubility-Product Constants for Compounds at 25 °C

Name	Formula	K_{sp}	Name	Formula	K_{sp}
Barium carbonate	BaCO ₃	5.0×10^{-9}	Lead(II) fluoride	PbF ₂	3.6×10^{-8}
Barium chromate	BaCrO ₄	2.1×10^{-10}	Lead(II) sulfate	PbSO ₄	6.3×10^{-7}
Barium fluoride	BaF ₂	1.7×10^{-6}	Lead(II) sulfide*	PbS	3×10^{-28}
Barium oxalate	BaC ₂ O ₄	1.6×10^{-6}	Magnesium hydroxide	Mg(OH) ₂	1.8×10^{-11}
Barium sulfate	BaSO ₄	1.1×10^{-10}	Magnesium carbonate	MgCO ₃	3.5×10^{-8}
Cadmium carbonate	CdCO ₃	1.8×10^{-14}	Magnesium oxalate	MgC ₂ O ₄	8.6×10^{-5}
Cadmium hydroxide	Cd(OH) ₂	2.5×10^{-14}	Manganese(II) carbonate	MnCO ₃	5.0×10^{-10}
Cadmium sulfide*	CdS	8×10^{-28}	Manganese(II) hydroxide	Mn(OH) ₂	1.6×10^{-13}
Calcium carbonate (calcite)	CaCO ₃	4.5×10^{-9}	Manganese(II) sulfide*	MnS	2×10^{-53}
Calcium chromate	CaCrO ₄	4.5×10^{-9}	Mercury(I) chloride	Hg ₂ Cl ₂	1.2×10^{-18}
Calcium fluoride	CaF ₂	3.9×10^{-11}	Mercury(I) iodide	Hg ₂ I ₂	1.1×10^{-11}
Calcium hydroxide	Ca(OH) ₂	6.5×10^{-6}	Mercury(II) sulfide*	HgS	2×10^{-53}
Calcium phosphate	Ca ₃ (PO ₄) ₂	2.0×10^{-29}	Nickel(II) carbonate	NiCO ₃	1.3×10^{-7}
Calcium sulfate	CaSO ₄	2.4×10^{-5}	Nickel(II) hydroxide	Ni(OH) ₂	6.0×10^{-16}
Chromium(III) hydroxide	Cr(OH) ₃	1.6×10^{-30}	Nickel(II) sulfide*	NiS	3×10^{-20}
Cobalt(II) carbonate	CoCO ₃	1.0×10^{-10}	Silver bromate	AgBrO ₃	5.5×10^{-13}
Cobalt(II) hydroxide	Co(OH) ₂	1.3×10^{-15}	Silver bromide	AgBr	5.0×10^{-13}
Cobalt(II) sulfide*	CoS	5×10^{-22}	Silver carbonate	Ag ₂ CO ₃	8.1×10^{-12}

CHAPTER 1

1.1 (a) Pure element: i (b) mixture of elements: v, vi (c) pure compound: iv (d) mixture of an element and a compound: ii, iii 1.3 This kind of separation based on solubility differences is called *extraction*. The insoluble grounds are then separated from the coffee solution by *filtration*. 1.5 (a) The aluminum sphere is lightest, then nickel, then silver. (b) The platinum sphere is largest, then gold, then lead. 1.7 (a) 7.5 cm; two significant figures (sig figs) (b) 72 mi/hr (inner scale, two significant figures) or 115 km/hr (outer scale, three significant figures) 1.9 Arrange the conversion factor so that the given unit cancels and the desired unit is in the correct position. 1.11 (a) Heterogeneous mixture (b) homogeneous mixture (heterogeneous if there are undissolved particles) (c) pure substance (d) pure substance. 1.13 (a) S (b) Au (c) K (d) Cl (e) Cu (f) uranium (g) nickel (h) sodium (i) aluminum (j) silicon 1.15 C is a compound; it contains both carbon and oxygen. A is a compound; it contains at least carbon and oxygen. B is not defined by the data given; it is probably also a compound because few elements exist as white solids. 1.17 Physical properties: silvery white; lustrous; melting point = 649 °C; boiling point = 1105 °C; density at 20 °C = 1.738 g/cm³; pounded into sheets; drawn into wires; good conductor. Chemical properties: burns in air; reacts with Cl₂. 1.19 (a) Chemical (b) physical (c) physical (d) chemical (e) chemical 1.21 (a) Add water to dissolve the sugar; filter this mixture, collecting the sand on the filter paper and the sugar water in the flask. Evaporate water from the flask to recover solid sugar. (b) Allow the mixture to settle so that there are two distinct layers. Carefully pour off most of the top oil layer. After the layers reform, use a dropper to remove any remaining oil. Vinegar is in the original vessel and oil is in a second container. 1.23 (a) 1 × 10⁻¹ (b) 1 × 10⁻² (c) 1 × 10⁻¹⁵ (d) 1 × 10⁻⁶ (e) 1 × 10⁶ (f) 1 × 10³ (g) 1 × 10⁻⁹ (h) 1 × 10⁻³ (i) 1 × 10⁻¹² 1.25 (a) 22 °C (b) 422.1 °F (c) 506 K (d) 107 °C (e) 1644 K (f) -459.67 °F 1.27 (a) 1.62 g/mL. Tetrachloroethylene, 1.62 g/mL, is more dense than water, 1.00 g/mL; tetrachloroethylene will sink rather than float on water. (b) 11.7 g 1.29 (a) Calculated density = 0.86 g/mL. The substance is probably toluene, density = 0.866 g/mL. (b) 40.4 mL ethylene glycol (c) 1.11 × 10³ g nickel 1.31 28 Pg 1.33 Exact: (c), (d), and (f) 1.35 (a) 3 (b) 2 (c) 5 (d) 3 (e) 5 (f) 1 1.37 (a) 1.025 × 10² (b) 6.570 × 10⁵ (c) 8.543 × 10⁻³ (d) 2.579 × 10⁻⁴ (e) -3.572 × 10⁻² 1.39 (a) 17.00 (b) 812.0 (c) 8.23 × 10³ (d) 8.69 × 10⁻² 1.41 5 significant figures

1.43 (a) $\frac{1 \times 10^{-3} \text{ m}}{1 \text{ mm}} \times \frac{1 \text{ nm}}{1 \times 10^{-9} \text{ m}}$ (b) $\frac{1 \times 10^{-3} \text{ g}}{1 \text{ mg}} \times \frac{1 \text{ kg}}{1000 \text{ g}}$

(c) $\frac{1000 \text{ m}}{1 \text{ km}} \times \frac{1 \text{ cm}}{1 \times 10^{-2} \text{ m}} \times \frac{1 \text{ in.}}{2.54 \text{ cm}} \times \frac{1 \text{ ft}}{12 \text{ in.}}$ (d) $\frac{(2.54)^3 \text{ cm}^3}{1^3 \text{ in.}^3}$

1.45 (a) 54.7 km/hr (b) 1.3 × 10³ gal (c) 46.0 m (d) 0.984 in/hr 1.47 (a) 4.32 × 10⁵ s (b) 88.5 m (c) \$0.499/L (d) 46.6 km/hr (e) 1.420 L/s (f) 707.9 cm³ 1.49 (a) 1.2 × 10² L (b) 5 × 10² mg (c) 19.9 mi/gal (2 × 10¹ mi/gal for 1 significant figure) (d) 26 mL/g (3 × 10¹ mL/g for 1 significant figure) 1.51 64 kg air 1.53 14-in. shoe < 57-cm string < 1.1-m pipe 1.55 \$6 × 10⁴ 1.59 8.47 g O; the law of constant composition 1.62 (a) Volume (b) area (c) volume (d) density (e) time (f) length (g) temperature 1.65 (a) 1.13 × 10⁵ quarters (b) 6.41 × 10⁵ g (c) \$2.83 × 10⁴ (d) 4.13 × 10⁸ stacks 1.68 The most dense liquid, Hg, will sink; the least dense, cyclohexane, will float; H₂O will be in the middle. 1.71 density of solid = 1.63 g/mL 1.74 (a) Density of peat = 0.13 g/cm³, density of soil = 2.5 g/cm³. It is not correct to say that peat is “lighter” than topsoil. Volumes must be specified in order to compare masses. (b) Buy 16 bags of peat (more than 15 are needed). (Results to 1 significant figure are not meaningful.) 1.77 The inner diameter of the tube is 1.13 cm. 1.79 The separation

is successful if two distinct spots are seen on the paper. To quantify the characteristics of the separation, calculate a reference value for each spot: distance traveled by spot/distance traveled by solvent. If the values for the two spots are fairly different, the separation is successful.

CHAPTER 2

2.1 (a) The path of the charged particle bends because the particle is repelled by the negatively charged plate and attracted to the positively charged plate. (b) (-) (c) increase (d) decrease 2.4 The particle is an ion. ${}_{16}^{32}\text{S}^{2-}$ 2.6 Formula: IF₅; name: iodine pentafluoride; the compound is molecular. 2.9 Postulate 4 of the atomic theory states that the relative number and kinds of atoms in a compound are constant, regardless of the source. Therefore, 1.0 g of pure water should always contain the same relative amounts of hydrogen and oxygen, no matter where or how the sample is obtained. 2.11 (a) 0.5711 g O/1 g N; 1.142 g O/1 g N; 2.284 g O/1 g N; 2.855 g O/1 g N (b) The numbers in part (a) obey the law of multiple proportions. Multiple proportions arise because atoms are the indivisible entities combining, as stated in Dalton's atomic theory. 2.13 (1) Electric and magnetic fields deflected the rays in the same way they would deflect negatively charged particles. (2) A metal plate exposed to cathode rays acquired a negative charge. 2.15 (a) Most of the volume of an atom is empty space in which electrons move. Most alpha particles passed through this space. (b) The few alpha particles that hit the massive, positively charged gold nuclei were strongly repelled and deflected back in the direction they came from. (c) Because the Be nuclei have a smaller volume and a smaller positive charge than the Au nuclei, fewer alpha particles will be scattered and fewer will be strongly back scattered. 2.17 (a) 0.135 nm; 1.35 × 10² or 135 pm (b) 3.70 × 10⁶ Au atoms (c) 1.03 × 10⁻²³ cm³ 2.19 (a) Proton, neutron, electron (b) proton = 1+, neutron = 0, electron = 1- (c) The neutron is most massive. (The neutron and proton have very similar masses.) (d) The electron is least massive. 2.21 (a) Atomic number is the number of protons in the nucleus of an atom. Mass number is the total number of nuclear particles, protons plus neutrons, in an atom. (b) mass number 2.23 (a) ${}^{40}\text{Ar}$: 18 p, 22 n, 18 e (b) ${}^{65}\text{Zn}$: 30 p, 35 n, 30 e (c) ${}^{70}\text{Ga}$: 31 p, 39 n, 31 e (d) ${}^{80}\text{Br}$: 35 p, 45 n, 35 e (e) ${}^{184}\text{W}$: 74 p, 110 n, 74 e (f) ${}^{243}\text{Am}$: 95 p, 148 n, 95e

2.27 (a) ${}^{196}\text{Pt}$ (b) ${}^{84}\text{Kr}$ (c) ${}^{75}\text{As}$ (d) ${}^{24}\text{Mg}$ 2.29 (a) ${}^{12}\text{C}$ (b) Atomic weights are average atomic masses, the sum of the mass of each naturally occurring isotope of an element times its fractional abundance. Each B atom will have the mass of one of the naturally occurring isotopes, while the “atomic weight” is an average value. 2.31 63.55 amu 2.33 (a) In Thomson's cathode-ray experiments and in mass spectrometry, a stream of charged particles is passed through the poles of a magnet. The charged particles are deflected by the magnetic field according to their mass and charge. (b) The x-axis label is atomic weight, and the y-axis label is signal intensity. (c) Uncharged particles are not deflected in a magnetic field. The effect of the magnetic field on charged moving particles is the basis of their separation by mass. 2.35 (a) average atomic mass = 24.31 amu

2.37 (a) Cr, 24 (metal) (b) He, 2 (nonmetal) (c) P, 15 (nonmetal) (d) Zn, 30 (metal) (e) Mg, 12 (metal) (f) Br, 35 (nonmetal) (g) As, 33 (metalloid) 2.39 (a) K, alkali metals (metal) (b) I, halogens (nonmetal) (c) Mg, alkaline earth metals (metal) (d) Ar, noble gases (nonmetal) (e) S, chalcogens (nonmetal) 2.41 An empirical formula shows the simplest mole ratio of elements in a compound. A molecular formula shows the exact number and kinds of atoms in a molecule. A structural formula shows which atoms are attached to which. 2.43 (a) AlBr_3 (b) C_4H_5 (c) $\text{C}_2\text{H}_4\text{O}$ (d) P_2O_5 (e) $\text{C}_3\text{H}_2\text{Cl}$ (f) BNH_2 2.45 (a) 6 (b) 6 (c) 12

2.79

2.82 (a) 2 protons, 1 neutron, 2 electrons (b) tritium, ^3H , is more massive. (c) A precision of 1×10^{-27} g would be required to differentiate between $^3\text{H}^+$ and $^3\text{He}^+$. 2.84 Arrangement A, 4.1×10^{14} atoms/cm² (b) Arrangement B, 4.7×10^{14} atoms/cm² (c) The ratio of atoms going from arrangement B to arrangement A is 1.2 to 1. In three dimensions, arrangement B leads to a greater density for Rb metal. 2.87 (a) ^{16}O , ^{17}O , ^{18}O (b) All isotopes are atoms of the same element, oxygen, with the same atomic number, 8 protons in the nucleus and 8 electrons. We expect their electron arrangements to be the same and their chemical properties to be very similar. Each has a different number of neutrons, a different mass number, and a different atomic mass. 2.90 (a) ^{69}Ga , 31 protons, 38 neutrons; ^{71}Ga , 31 protons, 40 neutrons (b) ^{69}Ga , 60.3%, ^{71}Ga , 39.7%. 2.93 (a) 5 significant figures (b) An electron is 0.05444% of the mass of an ^1H atom. 2.96 Strontium is an alkaline earth metal, similar in chemical properties to calcium and magnesium. Harmful strontium closely mimics essential calcium and magnesium, then behaves badly when the body tries to use it as it uses calcium and

magnesium. **2.98** (a) Nickel(II) oxide, 2+ (b) manganese(IV) oxide, 4+ (c) chromium(III) oxide, 3+ (d) molybdenum(VI) oxide, 6+ **2.101** (a) Perbromate ion (b) selenite ion (c) AsO_4^{3-} (d) HTeO_4^- **2.104** (a) Potassium nitrate (b) sodium carbonate (c) calcium oxide (d) hydrochloric acid (e) magnesium sulfate (f) magnesium hydroxide

CHAPTER 3

3.1 Equation (a) best fits the diagram. **3.3** (a) NO_2 (b) No, because we have no way of knowing whether the empirical and molecular formulas are the same. NO_2 represents the simplest ratio of atoms in a molecule but not the only possible molecular formula. **3.5** (a) $\text{C}_2\text{H}_5\text{NO}_2$ (b) 75.0 g/mol (c) 225 g glycine (d) Mass %N in glycine is 18.7%.

3.7

$\text{N}_2 + 3 \text{H}_2 \longrightarrow 2 \text{NH}_3$. Eight N atoms (4 N_2 molecules) require 24 H atoms (12 H_2 molecules) for complete reaction. Only 9 H_2 molecules are available, so H_2 is the limiting reactant. Nine H_2 molecules (18 H atoms) determine that 6 NH_3 molecules are produced. One N_2 molecule is in excess. **3.9** (a) Conservation of mass (b) Subscripts in chemical formulas should not be changed when balancing equations, because changing the subscript changes the identity of the compound (*law of constant composition*). (c) $\text{H}_2\text{O}(l)$, $\text{H}_2\text{O}(g)$, $\text{NaCl}(aq)$, $\text{NaCl}(s)$

3.15 (a) Determine the formula by balancing the positive and negative charges in the ionic product. All ionic compounds are solids.

The products are $\text{CO}_2(g)$ and $\text{H}_2\text{O}(l)$.

3.21 (a) 63.0 amu (b) 158.0 amu (c) 310.3 amu (d) 60.1 amu (e) 235.7 amu (f) 392.3 amu (g) 137.5 amu **3.23** (a) 16.8% (b) 16.1% (c) 21.1% (d) 28.8% (e) 27.2% (f) 26.5% **3.25** (a) 79.2% (b) 63.2%

(c) 64.6% **3.27** (a) 6.022×10^{23} (b) The formula weight of a substance in amu has the same numerical value as the molar mass expressed in grams. **3.29** 23 g Na contains 1 mol of atoms; 0.5 mol H_2O contains 1.5 mol atoms; 6.0×10^{23} N_2 molecules contain 2 mol of atoms. **3.31** 4.37×10^{25} kg (assuming 160 lb has 3 significant figures). One mole of people weighs 7.31 times as much as Earth. **3.33** (a) 35.9 g $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ (b) 0.75766 mol $\text{Zn}(\text{NO}_3)_2$ (c) 6.0×10^{17} $\text{CH}_3\text{CH}_2\text{OH}$ molecules (d) 2.47×10^{23} N atoms **3.35** (a) 0.373 g $(\text{NH}_4)_3\text{PO}_4$ (b) 5.737×10^{-3} mol Cl^- (c) 0.248 g $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2$ (d) 387 g cholesterol/mol **3.37** (a) Molar mass = 162.3 g (b) 3.08×10^{-5} mol allicin (c) 1.86×10^{19} allicin molecules (d) 3.71×10^{19} S atoms **3.39** (a) 2.500×10^{21} H atoms (b) 2.083×10^{20} $\text{C}_6\text{H}_{12}\text{O}_6$ molecules (c) 3.460×10^{-4} mol $\text{C}_6\text{H}_{12}\text{O}_6$ (d) 0.06227 g $\text{C}_6\text{H}_{12}\text{O}_6$ **3.41** 3.2×10^{-8} mol $\text{C}_2\text{H}_3\text{Cl}/\text{L}$; 1.9×10^{16} molecules/L **3.43** (a) $\text{C}_2\text{H}_6\text{O}$ (b) Fe_2O_3 (c) CH_2O **3.45** (a) CSCl_2 (b) C_3OF_6 (c) Na_3AlF_6 **3.47** 31 g/mol **3.49** (a) C_6H_{12} (b) NH_2Cl **3.51** (a) Empirical formula, CH ; molecular formula, C_8H_8 (b) empirical formula, $\text{C}_4\text{H}_5\text{N}_2\text{O}$; molecular formula, $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2$ (c) empirical formula and molecular formula, $\text{NaC}_5\text{H}_8\text{O}_4\text{N}$ **3.53** (a) C_7H_8 (b) The empirical and molecular formulas are $\text{C}_{10}\text{H}_{20}\text{O}$. **3.55** The molecular formula from the model is $\text{C}_8\text{H}_{16}\text{O}_2$, which corresponds to an empirical formula of $\text{C}_4\text{H}_8\text{O}$. The results from combustion analysis are consistent with this empirical formula. **3.57** $x = 10$; $\text{Na}_2\text{CO}_3 \cdot 10 \text{H}_2\text{O}$ **3.59** If the equation is not balanced, the mole ratios derived from the coefficients will be incorrect and lead to erroneous calculated amounts of products. **3.61** (a) 2.40 mol HF (b) 5.25 g NaF (c) 0.610 g Na_2SiO_3 **3.63** (a) $\text{Al}(\text{OH})_3(s) + 3 \text{HCl}(aq) \longrightarrow \text{AlCl}_3(aq) + 3 \text{H}_2\text{O}(l)$ (b) 0.701 g HCl (c) 0.855 g AlCl_3 ; 0.347 g H_2O (d) Mass of reactants = 0.500 g + 0.701 g = 1.201 g; mass of products = 0.855 g + 0.347 g = 1.202 g. Mass is conserved, within the precision of the data. **3.65** (a) $\text{Al}_2\text{S}_3(s) + 6 \text{H}_2\text{O}(l) \longrightarrow 2 \text{Al}(\text{OH})_3(s) + 3 \text{H}_2\text{S}(g)$ (b) 14.7 g $\text{Al}(\text{OH})_3$ **3.67** (a) 2.25 mol N_2 (b) 15.5 g NaN_3 (c) 548 g NaN_3 **3.69** (a) 5.50×10^{-3} mol Al (b) 1.47 g AlBr_3 **3.71** (a) The limiting reactant determines the maximum number of product moles resulting from a chemical reaction; any other reactant is an excess reactant. (b) The limiting reactant regulates the amount of products because it is completely used up during the reaction; no more product can be made when one of the reactants is unavailable. (c) Combining ratios are molecule and mole ratios. Since different molecules have different masses, comparing initial masses of reactants will not provide a comparison of numbers of molecules or moles. **3.73** (a) 2255 bicycles (b) 50 frames left over, 305 wheels left over (c) the handlebars **3.75** NaOH is the limiting reactant; 0.925 mol Na_2CO_3 can be produced; 0.075 mol CO_2 remains. **3.77** (a) NaHCO_3 is the limiting reactant. (b) 0.524 g CO_2 (c) 0.238 g citric acid remains **3.79** 0.00 g AgNO_3 (limiting reactant), 1.94 g Na_2CO_3 , 4.06 g Ag_2CO_3 , 2.50 g NaNO_3 **3.81** (a) The theoretical yield is 60.3 g $\text{C}_6\text{H}_5\text{Br}$. (b) 70.1% yield **3.83** 28 g S_8 actual yield **3.85** (a) $\text{C}_2\text{H}_4\text{O}_2(l) + 2 \text{O}_2(g) \longrightarrow 2 \text{CO}_2(g) + 2 \text{H}_2\text{O}(l)$ (b) $\text{Ca}(\text{OH})_2(s) \longrightarrow \text{CaO}(s) + \text{H}_2\text{O}(g)$ (c) $\text{Ni}(s) + \text{Cl}_2(g) \longrightarrow \text{NiCl}_2(s)$ **3.89** (a) 8×10^{-20} g Si (b) 2×10^3 Si atoms (with 2 significant figures, 1700 Si atoms) (c) 1×10^3 Ge atoms (with 2 significant figures, 1500 Ge atoms) **3.93** $\text{C}_8\text{H}_8\text{O}_3$ **3.97** (a) 1.19×10^{-5} mol NaI (b) 8.1×10^{-3} g NaI **3.101** 7.5 mol H_2 and 4.5 mol N_2 present initially **3.105** 6.46×10^{24} O atoms **3.107** (a) 88 kg CO_2 (b) 4×10^2 (400) kg CO_2 **3.109** (a) $\text{S}(s) + \text{O}_2(g) \longrightarrow \text{SO}_2(g)$; $\text{SO}_2(g) + \text{CaO}(s) \longrightarrow \text{CaSO}_3(s)$ (b) 7.9×10^7 g CaO (c) 1.7×10^8 g CaSO_3

CHAPTER 4

4.1 Diagram (c) represents Li_2SO_4 **4.3** (a) HCOOH is a weak electrolyte. (b) HNO_3 is a strong electrolyte. (c) $\text{CH}_3\text{CH}_2\text{OH}$ is a non-electrolyte. **4.5** BaCl_2 **4.7** (b) NO_3^- and (c) NH_4^+ will always be spectator ions. **4.9** In a redox reaction, electrons are transferred from the oxidized substance to the reduced substance. In an acid-base reaction, protons are transferred from an acid to a base. **4.11** No. Electrolyte solutions conduct electricity because the dissolved ions carry charge through the solution from one electrode to the other. **4.13** Although H_2O molecules are electrically neutral, there is an unequal distribution of electrons throughout the molecule. The partially

positive ends of H₂O molecules are attracted to anions in the solid, while the partially negative ends are attracted to cations. Thus, both cations and anions in an ionic solid are surrounded and separated (dissolved) by H₂O. We do not expect ionic compounds to be soluble in molecular liquids such as Br₂(l) or Hg(l). There is a symmetrical charge distribution in Hg atoms and Br₂ molecules, so there are no attractive forces to stabilize the separated ions of an ionic solid.

4.17 HCOOH molecules, H⁺ ions, and HCOO⁻ ions;
 $\text{HCOOH}(aq) \rightleftharpoons \text{H}^+(aq) + \text{HCOO}^-(aq)$ **4.19** (a) Soluble
 (b) insoluble (c) soluble (d) soluble (e) soluble **4.21** (a) $\text{Na}_2\text{CO}_3(aq) + 2\text{AgNO}_3(aq) \longrightarrow \text{Ag}_2\text{CO}_3(s) + 2\text{NaNO}_3(aq)$

(b) No precipitate (c) $\text{FeSO}_4(aq) + \text{Pb}(\text{NO}_3)_2(aq) \longrightarrow \text{PbSO}_4(s) + \text{Fe}(\text{NO}_3)_2(aq)$ **4.23** (a) Na⁺, SO₄²⁻ (b) Na⁺, NO₃⁻ (c) NH₄⁺, Cl⁻
4.25 The solution contains Pb²⁺

4.27

Compound	Ba(NO ₃) ₂ Result	NaCl Result
AgNO ₃ (aq)	No ppt	AgCl ppt
CaCl ₂ (aq)	No ppt	No ppt
Al ₂ (SO ₄) ₃ (aq)	BaSO ₄ ppt	No ppt

This sequence of tests would definitely identify the bottle contents.

4.29 LiOH is a strong base, HI is a strong acid, and CH₃OH is a molecular compound and nonelectrolyte. The strong acid HI will have the greatest concentration of solvated protons. **4.31** (a) A monoprotic acid has one ionizable (acidic) H, whereas a diprotic acid has two.

(b) A strong acid is completely ionized in aqueous solution, whereas only a fraction of weak acid molecules are ionized. (c) An acid is an H⁺ donor, and a base is an H⁺ acceptor. **4.33** When each of the strong acids in Table 4.2 dissociates, the anions formed are the same ones that normally form soluble ionic compounds (Table 4.1). The one exception is acetate, CH₃COO⁻, the anion of a weak acid. **4.35** (a) Acid, mixture of ions and molecules (weak electrolyte) (b) none of the above, entirely molecules (nonelectrolyte) (c) salt, entirely ions (strong electrolyte) (d) base, entirely ions (strong electrolyte) **4.37** (a) H₂SO₃, weak electrolyte (b) C₂H₅OH, nonelectrolyte (c) NH₃, weak electrolyte (d) KClO₃, strong electrolyte (e) Cu(NO₃)₂, strong electrolyte

4.39 (a) $2\text{HBr}(aq) + \text{Ca}(\text{OH})_2(aq) \longrightarrow \text{CaBr}_2(aq) + 2\text{H}_2\text{O}(l)$;
 $\text{H}^+(aq) + \text{OH}^-(aq) \longrightarrow \text{H}_2\text{O}(l)$ (b) $\text{Cu}(\text{OH})_2(s) + 2\text{HClO}_4(aq) \longrightarrow \text{Cu}(\text{ClO}_4)_2(aq) + 2\text{H}_2\text{O}(l)$;
 $\text{Cu}(\text{OH})_2(s) + 2\text{H}^+(aq) \longrightarrow 2\text{H}_2\text{O}(l) + \text{Cu}^{2+}(aq)$ (c) $\text{Al}(\text{OH})_3(s) + 3\text{HNO}_3(aq) \longrightarrow \text{Al}(\text{NO}_3)_3(aq) + 3\text{H}_2\text{O}(l)$;
 $\text{Al}(\text{OH})_3(s) + 3\text{H}^+(aq) \longrightarrow 3\text{H}_2\text{O}(l) + \text{Al}^{3+}(aq)$ **4.41** (a) $\text{CdS}(s) + \text{H}_2\text{SO}_4(aq) \longrightarrow \text{CdSO}_4(aq) + \text{H}_2\text{S}(g)$;
 $\text{CdS}(s) + 2\text{H}^+(aq) \longrightarrow \text{H}_2\text{S}(g) + \text{Cd}^{2+}(aq)$

(b) $\text{MgCO}_3(s) + 2\text{HClO}_4(aq) \longrightarrow \text{Mg}(\text{ClO}_4)_2(aq) + \text{H}_2\text{O}(l) + \text{CO}_2(g)$;
 $\text{MgCO}_3(s) + 2\text{H}^+(aq) \longrightarrow \text{H}_2\text{O}(l) + \text{CO}_2(g) + \text{Mg}^{2+}(aq)$

4.43 (a) $\text{MgCO}_3(s) + 2\text{HCl}(aq) \longrightarrow \text{MgCl}_2(aq) + \text{H}_2\text{O}(l) + \text{CO}_2(g)$;
 $\text{MgCO}_3(s) + 2\text{H}^+(aq) \longrightarrow \text{Mg}^{2+}(aq) + \text{H}_2\text{O}(l) + \text{CO}_2(g)$;
 $\text{MgO}(s) + 2\text{HCl}(aq) \longrightarrow \text{MgCl}_2(aq) + \text{H}_2\text{O}(l)$;
 $\text{MgO}(s) + 2\text{H}^+(aq) \longrightarrow \text{Mg}^{2+}(aq) + \text{H}_2\text{O}(l)$;
 $\text{Mg}(\text{OH})_2(s) + 2\text{HCl}(aq) \longrightarrow \text{MgCl}_2(aq) + 2\text{H}_2\text{O}(l)$;
 $\text{Mg}(\text{OH})_2(s) + 2\text{H}^+(aq) \longrightarrow \text{Mg}^{2+}(aq) + 2\text{H}_2\text{O}(l)$ (b) Yes. The reaction involving magnesium carbonate, MgCO₃(s), produces CO₂(g), which appears as bubbles. The other two reactions are calm. (c) If excess HCl(aq) is added in each case, the identity of the ions in the clear product solution is the same. The ions are Mg²⁺(aq); Cl⁻(aq); and H⁺(aq). **4.45** (a) In terms of electron transfer, oxidation is the loss of electrons by a substance and reduction is the gain of electrons (LEO says GER). (b) Relative to oxidation numbers, when a substance is oxidized, its oxidation number increases. When a substance is reduced, its oxidation number decreases. **4.47** Metals in region A are most easily oxidized. Nonmetals in region D are least easily oxidized.

4.49 (a) +4 (b) +4 (c) +7 (d) +1 (e) 0 (f) -1

4.51 (a) N₂ → 2 NH₃, N is reduced; 3 H₂ → 2 NH₃, H is oxidized (b) Fe²⁺ → Fe, Fe is reduced; Al → Al³⁺, Al is oxidized (c) Cl₂ → 2 Cl⁻, Cl is reduced; 2 I⁻ → I₂, I is oxidized (d) S²⁻ → SO₄²⁻, S is oxidized; H₂O₂ → H₂O, O is reduced

4.53 (a) $\text{Mn}(s) + \text{H}_2\text{SO}_4(aq) \longrightarrow \text{MnSO}_4(aq) + \text{H}_2(g)$;

$\text{Mn}(s) + 2\text{H}^+(aq) \longrightarrow \text{Mn}^{2+}(aq) + \text{H}_2(g)$

(b) $2\text{Cr}(s) + 6\text{HBr}(aq) \longrightarrow 2\text{CrBr}_3(aq) + 3\text{H}_2(g)$;

$2\text{Cr}(s) + 6\text{H}^+(aq) \longrightarrow 2\text{Cr}^{3+}(aq) + 3\text{H}_2(g)$

(c) $\text{Sn}(s) + 2\text{HCl}(aq) \longrightarrow \text{SnCl}_2(aq) + \text{H}_2(g)$;

$\text{Sn}(s) + 2\text{H}^+(aq) \longrightarrow \text{Sn}^{2+}(aq) + \text{H}_2(g)$

(d) $2\text{Al}(s) + 6\text{HCOOH}(aq) \longrightarrow 2\text{Al}(\text{HCOO})_3(aq) + 3\text{H}_2(g)$;

$2\text{Al}(s) + 6\text{HCOOH}(aq) \longrightarrow 2\text{Al}^{3+}(aq) + 6\text{HCOO}^-(aq) + 3\text{H}_2(g)$

4.55 (a) $\text{Fe}(s) + \text{Cu}(\text{NO}_3)_2(aq) \longrightarrow \text{Fe}(\text{NO}_3)_2(aq) + \text{Cu}(s)$

(b) NR (c) $\text{Sn}(s) + 2\text{HBr}(aq) \longrightarrow \text{SnBr}_2(aq) + \text{H}_2(g)$ (d) NR

(e) $2\text{Al}(s) + 3\text{CoSO}_4(aq) \longrightarrow \text{Al}_2(\text{SO}_4)_3(aq) + 3\text{Co}(s)$

4.57 (a) i. $\text{Zn}(s) + \text{Cd}^{2+}(aq) \longrightarrow \text{Cd}(s) + \text{Zn}^{2+}(aq)$;

ii. $\text{Cd}(s) + \text{Ni}^{2+}(aq) \longrightarrow \text{Ni}(s) + \text{Cd}^{2+}(aq)$ (b) Cd is between Zn and Ni on the activity series. (c) Place an iron strip in CdCl₂(aq). If Cd(s) is deposited, Cd is less active than Fe; if there is no reaction, Cd is more active than Fe. Do the same test with Co if Cd is less active than Fe or with Cr if Cd is more active than Fe. **4.59** (a) Intensive; the ratio of amount of solute to total amount of solution is the same, regardless of how much solution is present. (b) The term 0.50 mol HCl defines an amount (~18 g) of the pure substance HCl. The term 0.50 M HCl is a ratio; it indicates that there is 0.50 mol of HCl solute in 1.0 liter of solution. **4.61** (a) 1.17 M ZnCl₂ (b) 0.158 mol HNO₃ (c) 54.2 mL of 6.00 M NaOH **4.63** 16 g Na⁺(aq) **4.65** BAC of 0.08 = 0.02 M CH₃CH₂OH (alcohol) **4.67** (a) 5.21 g KBr (b) 0.06537 M Ca(NO₃)₂ (c) 10.2 mL of 1.50 M Na₃PO₄ **4.69** (a) 0.15 M K₂CrO₄ has the highest K⁺ concentration. (b) 30.0 mL of 0.15 M K₂CrO₄ has more K⁺ ions. **4.71** (a) 0.25 M Na⁺, 0.25 M NO₃⁻ (b) 1.3 × 10⁻² M Mg²⁺, 1.3 × 10⁻² M SO₄²⁻ (c) 0.0150 M C₆H₁₂O₆ (d) 0.111 M Na⁺, 0.111 M Cl⁻, 0.0292 M NH₄⁺, 0.0146 M CO₃²⁻

4.73 (a) 16.9 mL 14.8 M NH₃ (b) 0.296 M NH₃ **4.75** (a) Add 21.4 g C₁₂H₂₂O₁₁ to a 250-mL volumetric flask, dissolve in a small volume of water, and add water to the mark on the neck of the flask. Agitate thoroughly to ensure total mixing. (b) Thoroughly rinse, clean, and fill a 50-mL buret with the 1.50 M C₁₂H₂₂O₁₁. Dispense 23.3 mL of this solution into a 350-mL volumetric container, add water to the mark, and mix thoroughly. **4.77** 1.398 M CH₃COOH **4.79** 0.227 g KCl **4.81** (a) 38.0 mL of 0.115 M HClO₄ (b) 769 mL of 0.128 M HCl (c) 0.408 M AgNO₃ (d) 0.275 g KOH **4.83** 27 g NaHCO₃

4.85 (a) Molar mass of metal hydroxide is 103 g/mol. (b) Rb⁺ **4.87** (a) $\text{NiSO}_4(aq) + 2\text{KOH}(aq) \longrightarrow \text{Ni}(\text{OH})_2(s) + \text{K}_2\text{SO}_4(aq)$ (b) Ni(OH)₂ (c) KOH is the limiting reactant. (d) 0.927 g Ni(OH)₂ (e) 0.0667 M Ni²⁺(aq), 0.0667 M K⁺(aq), 0.100 M SO₄²⁻(aq) **4.89** 91.40% Mg(OH)₂ **4.92** The precipitate is CdS(s). Na⁺(aq) and NO₃⁻(aq) remain in solution, along with any excess reactant ions. The net ionic equation is $\text{Cd}^{2+}(aq) + \text{S}^{2-}(aq) \longrightarrow \text{CdS}(s)$. **4.94** (a, b) Expt. 1: NR; Expt. 2: $2\text{Ag}^+(aq) + \text{CrO}_4^{2-}(aq) \longrightarrow \text{Ag}_2\text{CrO}_4(s)$ red precipitate; Expt. 3: $2\text{Ca}^{2+}(aq) + \text{CrO}_4^{2-}(aq) \longrightarrow \text{CaCrO}_4(s)$ yellow precipitate; Expt. 4: $2\text{Ag}^+(aq) + \text{C}_2\text{O}_4^{2-}(aq) \longrightarrow \text{Ag}_2\text{C}_2\text{O}_4(s)$ white precipitate; Expt. 5: $\text{Ca}^{2+}(aq) + \text{C}_2\text{O}_4^{2-}(aq) \longrightarrow \text{CaC}_2\text{O}_4(s)$ white precipitate; Expt. 6: $\text{Ag}^+(aq) + \text{Cl}^-(aq) \longrightarrow \text{AgCl}(s)$ white precipitate. **4.96** $4\text{NH}_3(g) + 5\text{O}_2(g) \longrightarrow 4\text{NO}(g) + 6\text{H}_2\text{O}(g)$. (a) redox reaction (b) N is oxidized, O is reduced. $2\text{NO}(g) + \text{O}_2(g) \longrightarrow 2\text{NO}_2(g)$. (a) redox reaction (b) N is oxidized, O is reduced. $3\text{NO}_2(g) + \text{H}_2\text{O}(l) \longrightarrow \text{HNO}_3(aq) + \text{NO}(g)$. (a) redox reaction (b) N is both oxidized and reduced. **4.99** 1.42 M KBr **4.100** (a) 2.2×10^{-9} M Na⁺ (b) 1.3×10^{12} Na⁺ ions

4.103 (a) 1.718 M Sr(OH)₂ (b) $2\text{HNO}_3(aq) + \text{Sr}(\text{OH})_2(s) \longrightarrow \text{Sr}(\text{NO}_3)_2(aq) + 2\text{H}_2\text{O}(l)$ (c) 2.61 M HNO₃ **4.106** (a) The molar-mass of the acid is 136 g/mol. (b) The molecular formula is C₈H₈O₂. **4.109** (a) $\text{Mg}(\text{OH})_2(s) + 2\text{HNO}_3(aq) \longrightarrow \text{Mg}(\text{NO}_3)_2(aq) + 2\text{H}_2\text{O}(l)$ (b) HNO₃ is the limiting reactant. (c) 0.0923 mol Mg(OH)₂, 0 mol HNO₃, and 0.00250 mol Mg(NO₃)₂ are present. **4.112** 1.766% Cl⁻ by mass **4.114** 1.5×10^{-5} g Na₃AsO₄ in 1.00 L H₂O

CHAPTER 5

5.1 (a) As the book falls, potential energy decreases and kinetic energy increases. (b) 71 J, assuming no transfer of energy as heat (c) A heavier book falling from the same shelf has greater kinetic energy when it hits the floor. 5.5 (a) No. The distance traveled to the top of a mountain depends on the path taken by the hiker. Distance is a path function, not a state function. (b) Yes. Change in elevation depends only on the location of the base camp and the height of the mountain, not on the path to the top. Change in elevation is a state function, not a path function. 5.8 (a) The sign of w is (+). (b) The internal energy of the system increases during the change; the sign of ΔE is (+). 5.11 (a) $\Delta H_A = \Delta H_B + \Delta H_C$. The diagram and equation both show that the net enthalpy change for a process is independent of path, that ΔH is a state function. (b) $\Delta H_Z = \Delta H_X + \Delta H_Y$. (c) Hess's law states that the enthalpy change for net reaction Z is the sum of the enthalpy changes for steps X and Y , regardless of whether the reaction actually occurs via this path. The diagrams are a visual statement of Hess's law. 5.13 An object can possess energy by virtue of its motion or position. Kinetic energy depends on the mass of the object and its velocity. Potential energy depends on the position of the object relative to the body with which it interacts. 5.15 (a) 1.9×10^5 J (b) 4.6×10^4 cal (c) As the automobile brakes to a stop, its speed (and hence its kinetic energy) drops to zero. The kinetic energy of the automobile is primarily transferred to friction between brakes and wheels and somewhat to deformation of the tire and friction between the tire and road. 5.17 1 Btu = 1054 J 5.19 (a) The *system* is the well-defined part of the universe whose energy changes are being studied. (b) A *closed system* can exchange heat but not mass with its surroundings. (c) Any part of the universe not part of the system is called the surroundings. 5.21 (a) Work is a force applied over a distance. (b) The amount of work done is the magnitude of the force times the distance over which it is applied. $w = F \times d$. 5.23 (a) Gravity; work is done because the force of gravity is opposed and the pencil is lifted. (b) Mechanical force; work is done because the force of the coiled spring is opposed as the spring is compressed over a distance. 5.25 (a) In any chemical or physical change, energy can be neither created nor destroyed; energy is conserved. (b) The *internal energy* (E) of a system is the sum of all the kinetic and potential energies of the system components. (c) Internal energy of a closed system increases when work is done on the system and when heat is transferred to the system. 5.27 (a) $\Delta E = -0.077$ kJ, endothermic (b) $\Delta E = -22.1$ kJ, exothermic (c) $\Delta E = 7.25$ kJ, endothermic 5.29 (a) Since no work is done by the system in case (2), the gas will absorb most of the energy as heat; the case (2) gas will have the higher temperature. (b) In case (2) $w = 0$ and $q = 100$ J. In case (1) energy will be used to do work on the surroundings ($-w$), but some will be absorbed as heat ($+q$). (c) ΔE is greater for case (2) because the entire 100 J increases the internal energy of the system rather than a part of the energy doing work on the surroundings. 5.31 (a) A *state function* is a property that depends only on the physical state (pressure, temperature, etc.) of the system, not on the route used to get to the current state. (b) Internal energy is a state function; heat is not a state function. (c) Volume is a state function. The volume of a system depends only on conditions (pressure, temperature, amount of substance), not the route or method used to establish that volume. 5.33 (a) ΔH is usually easier to measure than ΔE because at constant pressure, $\Delta H = q_p$. The heat flow associated with a process at constant pressure can easily be measured as a change in temperature, while measuring ΔE requires a means to measure both q and w . (b) H is a static quantity that depends only on the specific conditions of the system. q is an energy *change* that, in the general case, does depend on how the change occurs. We can equate change in enthalpy, ΔH , with heat, q_p , only for the specific conditions of constant pressure and exclusively P - V work. (c) The process is endothermic. 5.35 At constant pressure, $\Delta E = \Delta H - P\Delta V$. The values of either P and ΔV or T and Δn must be known to calculate ΔE from ΔH . 5.37 $\Delta E = 1.47$ kJ; $\Delta H = 0.824$ kJ 5.39 (a) $C_2H_5OH(l) + 3 O_2(g) \longrightarrow 3 H_2O + 2 CO_2(g)$, $\Delta H = -1235$ kJ

5.41 (a) $\Delta H = -142.3$ kJ/mol $O_3(g)$ (b) $2 O_3(g)$ has the higher enthalpy. 5.43 (a) Exothermic (b) -87.9 kJ heat transferred (c) 15.7 g MgO produced (d) 602 kJ heat absorbed 5.45 (a) -29.5 kJ (b) -4.11 kJ (c) 60.6 J 5.47 (a) $\Delta H = 726.5$ kJ (b) $\Delta H = -1453$ kJ (c) The exothermic forward reaction is more likely to be thermodynamically favored. (d) Vaporization is endothermic. If the product were $H_2O(g)$, the reaction would be more endothermic and would have a less negative ΔH . 5.49 (a) J/mol \cdot °C or J/mol \cdot K (b) J/g \cdot °C or J/g \cdot K (c) To calculate heat capacity from specific heat, the mass of the particular piece of copper pipe must be known. 5.51 (a) 4.184 J/g \cdot K (b) 75.40 J/mol \cdot °C (c) 774 J/°C (d) 904 kJ 5.53 (a) 2.66×10^3 J (b) It will require more heat to increase the temperature of one mole of octane, $C_8H_{18}(l)$, by a certain amount than to increase the temperature of one mole of water, $H_2O(l)$, by the same amount. 5.55 $\Delta H = -44.4$ kJ/mol NaOH 5.57 $\Delta H_{rxn} = -25.5$ kJ/g $C_6H_4O_2$ or -2.75×10^3 kJ/mol $C_6H_4O_2$ 5.59 (a) Heat capacity of the complete calorimeter = 14.4 kJ/°C (b) 7.56 °C 5.61 Hess's law is a consequence of the fact that enthalpy is a state function. Since ΔH is independent of path, we can describe a process by any series of steps that adds up to the overall process. ΔH for the process is the sum of ΔH values for the steps. 5.63 $\Delta H = -1300.0$ kJ 5.65 $\Delta H = -2.49 \times 10^3$ kJ 5.67 (a) *Standard conditions* for enthalpy changes are $P = 1$ atm and some common temperature, usually 298 K. (b) *Enthalpy of formation* is the enthalpy change that occurs when a compound is formed from its component elements. (c) *Standard enthalpy of formation* ΔH_f° is the enthalpy change that accompanies formation of one mole of a substance from elements in their standard states. 5.69 (a) $\frac{1}{2} N_2(g) + O_2(g) \longrightarrow NO_2(g)$, $\Delta H_f^\circ = 33.84$ kJ (b) $S(s) + 3/2 O_2(g) \longrightarrow SO_3(g)$, $\Delta H_f^\circ = -395.2$ kJ (c) $Na(s) + \frac{1}{2} Br_2(l) \longrightarrow NaBr(s)$, $\Delta H_f^\circ = -361.4$ kJ (d) $Pb(s) + N_2(g) + 3 O_2(g) \longrightarrow Pb(NO_3)_2(s)$, $\Delta H_f^\circ = -451.9$ kJ 5.71 $\Delta H_{rxn}^\circ = -847.6$ kJ 5.73 (a) $\Delta H_{rxn}^\circ = -196.6$ kJ (b) $\Delta H_{rxn}^\circ = 37.1$ kJ (c) $\Delta H_{rxn}^\circ = -976.94$ kJ (d) $\Delta H_{rxn}^\circ = -68.3$ kJ 5.75 $\Delta H_f^\circ = -248$ kJ 5.77 (a) $C_8H_{18}(l) + \frac{25}{2} O_2(g) \longrightarrow 8 CO_2(g) + 9 H_2O(g)$, $\Delta H = -5064.9$ kJ (b) $8 C(s, \text{graphite}) + 9 H_2(g) \longrightarrow C_8H_{18}(l)$ (c) $\Delta H_f^\circ = -259.5$ kJ 5.79 (a) $C_2H_5OH(l) + 3 O_2(g) \longrightarrow 2 CO_2(g) + 3 H_2O(g)$ (b) $\Delta H_{rxn}^\circ = -1234.8$ kJ (c) 2.11×10^4 kJ/L heat produced (d) 0.071284 g CO_2 /kJ heat emitted 5.81 (a) *Fuel value* is the amount of energy produced when 1 g of a substance (fuel) is combusted. (b) 5 g of fat (c) These products of metabolism are expelled as waste via the alimentary tract, $H_2O(l)$ primarily in urine and feces, and $CO_2(g)$ as gas. 5.83 108 or 1×10^2 Cal/serving (b) Sodium does not contribute to the calorie content of the food because it is not metabolized by the body. 5.85 59.7 Cal 5.87 (a) $\Delta H_{comb} = -1850$ kJ/mol C_3H_4 , -1926 kJ/mol C_3H_6 , -2044 kJ/mol C_3H_8 (b) $\Delta H_{comb} = -4.616 \times 10^4$ kJ/kg C_2H_4 , -4.578×10^4 kJ/kg C_3H_6 , -4.635×10^4 kJ/kg C_3H_8 (c) These three substances yield nearly identical quantities of heat per unit mass, but propane is marginally higher than the other two. 5.89 1×10^{12} kg $C_6H_{12}O_6$ /yr 5.91 (a) 469.4 m/s (b) 5.124×10^{-21} J (c) 3.086 kJ/mol 5.93 The spontaneous air bag reaction is probably exothermic, with $-\Delta H$ and thus $-q$. When the bag inflates, work is done by the system, so the sign of w is also negative. 5.97 $\Delta H = 38.95$ kJ; $\Delta E = 36.48$ kJ 5.102 (a) $\Delta H_{rxn}^\circ = -353.0$ kJ (b) 1.2 g Mg needed 5.106 (a) $\Delta H^\circ = -631.3$ kJ (b) 3 mol of acetylene gas has greater enthalpy. (c) Fuel values are 50 kJ/g $C_2H_2(g)$, 42 kJ/g $C_6H_6(l)$. 5.109 If all work is used to increase the man's potential energy, the stair climbing uses 58 Cal and will not compensate for the extra order of 245 Cal fries. (More than 58 Cal will be required to climb the stairs because some energy is used to move limbs and some will be lost as heat.)

5.112 (a) 1.479×10^{-18} J/molecule (b) 1×10^{-15} J/photon. The X-ray has approximately 1000 times more energy than is produced by the combustion of 1 molecule of $\text{CH}_4(\text{g})$. **5.114** (a) ΔH° for neutralization of the acids is HNO_3 , -55.8 kJ; HCl , -56.1 kJ; NH_4^+ , -4.1 kJ. (b) $\text{H}^+(\text{aq}) + \text{OH}^-(\text{aq}) \longrightarrow \text{H}_2\text{O}(\text{l})$ is the net ionic equation for the first two reactions. $\text{NH}_4^+(\text{aq}) + \text{OH}^-(\text{aq}) \longrightarrow \text{NH}_3(\text{aq}) + \text{H}_2\text{O}(\text{l})$ (c) The ΔH° values for the first two reactions are nearly identical, -55.8 kJ and -56.1 kJ. Since spectator ions do not change during a reaction and these two reactions have the same net ionic equation, it is not surprising that they have the same ΔH° . (d) Strong acids are more likely than weak acids to donate H^+ . Neutralization of the two strong acids is energetically favorable, while the third reaction is barely so. NH_4^+ is likely a weak acid. **5.116** (a) $\Delta H^\circ = -65.7$ kJ (b) ΔH° for the complete molecular equation will be the same as ΔH° for the net ionic equation. Since the overall enthalpy change is the enthalpy of products minus the enthalpy of reactants, the contributions of spectator ions cancel. (c) ΔH_f° for $\text{AgNO}_3(\text{aq})$ is -100.4 kJ/mol.

CHAPTER 6

6.2 (a) 0.1 m or 10 cm (b) No. Visible radiation has wavelengths much shorter than 0.1 m. (c) Energy and wavelength are inversely proportional. Photons of the longer 0.1-m radiation have less energy than visible photons. (d) Radiation with $\lambda = 0.1$ m is in the low-energy portion of the microwave region. The appliance is probably a microwave oven. **6.5** (a) Increase (b) decrease (c) the light from the hydrogen discharge tube is a line spectrum, so not all visible wavelengths will be in our "hydrogen discharge rainbow." Starting on the inside, the rainbow will be violet, then blue and blue-green. After a gap, the final band will be red. **6.8** (a) 1 (b) p (c) For the $n = 4$ shell, the lobes in the contour representation would extend farther along the y -axis. **6.11** (a) Meters (b) 1/second (c) meters/second **6.13** (a) True (b) False. Ultraviolet light has shorter wavelengths than visible light. (c) False. X-rays travel at the same speed as microwaves. (d) False. Electromagnetic radiation and sound waves travel at different speeds. **6.15** Wavelength of X-rays $<$ ultraviolet $<$ green light $<$ red light $<$ infrared $<$ radio waves **6.17** (a) $3.0 \times 10^{13} \text{ s}^{-1}$ (b) $5.45 \times 10^{-7} \text{ m} = 545 \text{ nm}$ (c) The radiation in (b) is visible; the radiation in (a) is not. (d) $1.50 \times 10^4 \text{ m}$ **6.19** $5.64 \times 10^{14} \text{ s}^{-1}$; green. **6.21** Quantization means that energy changes can happen only in certain allowed increments. If the human growth quantum is one foot, growth occurs instantaneously in one-foot increments. The child experiences growth spurts of one foot; her height can change only by one-foot increments. **6.23** (a) $4.47 \times 10^{-21} \text{ J}$ (b) $6.17 \times 10^{-19} \text{ J}$ (c) 69.2 nm **6.25** (a) $\lambda = 3.3 \mu\text{m}$, $E = 6.0 \times 10^{-20} \text{ J}$; $\lambda = 0.154 \text{ nm}$, $E = 1.29 \times 10^{-15} \text{ J}$ (b) The 3.3- μm photon is in the infrared region and the 0.154-nm photon is in the X-ray region; the X-ray photon has the greater energy. **6.27** (a) $6.11 \times 10^{-19} \text{ J/photon}$ (b) 368 kJ/mol (c) 1.64×10^{15} photons (d) 368 kJ/mol **6.29** (a) The $\sim 1 \times 10^{-6} \text{ m}$ radiation is in the infrared portion of the spectrum. (b) 8.1×10^{16} photons/s **6.31** (a) $E_{\text{min}} = 7.22 \times 10^{-19} \text{ J}$ (b) $\lambda = 275 \text{ nm}$ (c) $E_{120} = 1.66 \times 10^{-18} \text{ J}$. The excess energy of the 120-nm photon is converted into the kinetic energy of the emitted electron. $E_k = 9.3 \times 10^{-19} \text{ J/electron}$. **6.33** When applied to atoms, the notion of quantized energies means that only certain values of ΔE are allowed. These are represented by the lines in the emission spectra of excited atoms. **6.35** (a) Emitted (b) absorbed (c) emitted **6.37** (a) $E_2 = -5.45 \times 10^{-19} \text{ J}$; $E_6 = -0.606 \times 10^{-19} \text{ J}$; $\Delta E = 4.84 \times 10^{-19} \text{ J}$; $\lambda = 410 \text{ nm}$ (b) visible, violet **6.39** (a) Only lines with $n_f = 2$ represent ΔE values and wavelengths that lie in the visible portion of the spectrum. Lines with $n_f = 1$ have shorter wavelengths and lines with $n_f > 2$ have longer wavelengths than visible radiation. (b) $n_i = 3$, $n_f = 2$; $\lambda = 6.56 \times 10^{-7} \text{ m}$; this is the red line at 656 nm. $n_i = 4$, $n_f = 2$; $\lambda = 4.86 \times 10^{-7} \text{ m}$; this is the blue-green line at 486 nm. $n_i = 5$, $n_f = 2$; $\lambda = 4.34 \times 10^{-7} \text{ m}$; this is the blue-violet line at 434 nm. **6.41** (a) Ultraviolet region (b) $n_i = 6$, $n_f = 1$ **6.43** (a) $\lambda = 5.6 \times 10^{-37} \text{ m}$ (b) $\lambda = 2.65 \times 10^{-34} \text{ m}$ (c) $\lambda = 2.3 \times 10^{-13} \text{ m}$ (d) $\lambda = 1.51 \times 10^{-11} \text{ m}$ **6.45** $4.14 \times 10^3 \text{ m/s}$ **6.47** (a) $\Delta x \geq 4 \times 10^{-27} \text{ m}$ (b) $\Delta x \geq 3 \times 10^{-10} \text{ m}$ **6.49** (a) The uncertainty principle states that there is a limit to how precisely we can simultaneously

know the position and momentum (a quantity related to energy) of an electron. The Bohr model states that electrons move about the nucleus in precisely circular orbits of known radius and energy. This violates the uncertainty principle. (b) De Broglie stated that electrons demonstrate the properties of both particles and waves and that each moving particle has a wave associated with it. A wave function is the mathematical description of the matter wave of an electron. (c) Although we cannot predict the exact location of an electron in an allowed energy state, we can determine the probability of finding an electron at a particular position. This statistical knowledge of electron location is the *probability density* and is a function of Ψ^2 , the square of the wave function Ψ . **6.51** (a) $n = 4$, $l = 3, 2, 1, 0$ (b) $l = 2$, $m_l = -2, -1, 0, 1, 2$ (c) $m_l = 2$, $l \geq 2$ or $l = 2, 3$ or 4 **6.53** (a) $3p$: $n = 3$, $l = 1$ (b) $2s$: $n = 2$, $l = 0$ (c) $4f$: $n = 4$, $l = 3$ (d) $5d$: $n = 5$, $l = 2$ **6.55** (a) impossible, $1p$ (b) possible (c) possible (d) impossible, $2d$

6.59 (a) The hydrogen atom 1s and 2s orbitals have the same overall spherical shape, but the 2s orbital has a larger radial extension and one more node than the 1s orbital. (b) A single 2p orbital is directional in that its electron density is concentrated along one of the three Cartesian axes of the atom. The $d_{x^2-y^2}$ orbital has electron density along both the x - and y -axes, while the p_x orbital has density only along the x -axis. (c) The average distance of an electron from the nucleus in a 3s orbital is greater than for an electron in a 2s orbital. (d) $1s < 2p < 3d < 4f < 6s$ **6.61** (a) In the hydrogen atom, orbitals with the same principal quantum number, n , have the same energy. (b) In a many-electron atom, for a given n value, orbital energy increases with increasing l value: $s < p < d < f$. **6.63** (a) There are two main pieces of experimental evidence for electron "spin." The Stern-Gerlach experiment shows that atoms with a single unpaired electron interact differently with an inhomogeneous magnetic field. Examination of the fine details of emission line spectra of multi-electron atoms reveals that each line is really a close pair of lines. Both observations can be rationalized if electrons have the property of spin.

6.65 (a) 6 (b) 10 (c) 2 (d) 14 **6.67** (a) "Valence electrons" are those involved in chemical bonding. They are part or all of the outer-shell electrons listed after the core. (b) "Core electrons" are inner-shell electrons that have the electron configuration of the nearest noble-gas element. (c) Each box represents an orbital. (d) Each half-arrow in an orbital diagram represents an electron. The direction of the half-arrow represents electron spin. **6.69** (a) Cs, $[\text{Xe}]6s^1$ (b) Ni, $[\text{Ar}]4s^23d^8$ (c) Se, $[\text{Ar}]4s^23d^{10}4p^4$ (d) Cd, $[\text{Kr}]5s^24d^{10}$ (e) U, $[\text{Rn}]5f^36d^17s^2$ (f) Pb, $[\text{Xe}]6s^24f^{14}5d^{10}6p^2$ **6.71** (a) Be, 0 unpaired electrons (b) O, 2 unpaired electrons (c) Cr, 6 unpaired electrons (d) Te, 2 unpaired electrons **6.73** (a) The fifth electron would fill the 2p subshell before the 3s. (b) Either the core is $[\text{He}]$, or the outer electron configuration should be $3s^23p^3$. (c) The 3p subshell would fill before the 3d. **6.75** (a) $\lambda_A = 3.6 \times 10^{-8} \text{ m}$, $\lambda_B = 8.0 \times 10^{-8} \text{ m}$ (b) $\nu_A = 8.4 \times 10^{15} \text{ s}^{-1}$, $\nu_B = 3.7 \times 10^{15} \text{ s}^{-1}$ (c) A, ultraviolet; B, ultraviolet **6.78** 66.7 min **6.82** 1.6×10^7 photons/s, $5.1 \times 10^{-12} \text{ J/s}$ **6.85** (a) The Paschen series lies in the infrared. (b) $n_i = 4$, $\lambda = 1.87 \times 10^{-6} \text{ m}$; $n_i = 5$, $\lambda = 1.28 \times 10^{-6} \text{ m}$; $n_i = 6$, $\lambda = 1.09 \times 10^{-6} \text{ m}$ **6.90** (a) l (b) n and l (c) m_l (d) m_l **6.92** (a) The nodal plane of the p_z orbital is the xy -plane. (b) The two nodal planes of the d_{xy} orbital are the ones where

$x = 0$ and $y = 0$. These are the yz - and xz -planes. (c) The two nodal planes of the $d_{x^2-y^2}$ orbital are the ones that bisect the x - and y -axes and contain the z -axis. **6.94** If m_l had three allowed values instead of two, each orbital would hold three electrons instead of two. Assuming that there is no change in the n , l , and m_l values, the number of elements in each of the first four rows would be 1st row, 3 elements; 2nd row, 12 elements; 3rd row, 12 elements; 4th row, 27 elements. **6.97** (a) 1.7×10^{28} photons (b) 34 s **6.101** (a) Bohr's theory was based on the Rutherford nuclear model of the atom: a dense positive charge at the center and a diffuse negative charge surrounding it. Bohr's theory then specified the nature of the diffuse negative charge. The prevailing theory before the nuclear model was Thomson's plum pudding model: discrete electrons scattered about a diffuse positive charge cloud. Bohr's theory could not have been based on the Thomson model of the atom. (b) De Broglie's hypothesis is that electrons exhibit both particle and wave properties. Thomson's conclusion that electrons have mass is a particle property, while the nature of cathode rays is a wave property. De Broglie's hypothesis actually rationalizes these two seemingly contradictory observations about the properties of electrons.

CHAPTER 7

7.3 (a) The bonding atomic radius of A, r_A , is $d_1/2$; $r_x = d_2 - (d_1/2)$. (b) The length of the X—X bond is $2r_x$ or $2d_2 - d_1$. **7.6** (a) $X + 2F_2 \rightarrow XF_4$ (b) X in the diagram has about the same bonding radius as F, so it is likely to be a nonmetal. **7.7** The number of columns in the various blocks of the periodic chart corresponds to the maximum number of electrons that can occupy the various kinds of atomic orbitals: 2 columns on the left for 2 electrons in s orbitals, 10 columns in the transition metals for 10 electrons in d orbitals, 6 columns on the right for 6 electrons in p orbitals, 14-member rows below for 14 electrons in f orbitals. The order of blocks corresponds to the filling order of atomic orbitals, and the row number corresponds to the principal quantum number of the valence electrons of elements in that row, ns , np , $(n-1)d$, $(n-2)f$. **7.9** In general, elements are discovered according to their ease of isolation in elemental form. **7.11** (a) *Effective nuclear charge*, Z_{eff} , is a representation of the average electrical field experienced by a single electron. It is the average environment created by the nucleus and the other electrons in the molecule, expressed as a net positive charge at the nucleus. (b) Going from left to right across a period, effective nuclear charge increases. **7.13** (a) For both Na and K, $Z_{\text{eff}} = 1$. (b) For both Na and K, $Z_{\text{eff}} = 2.2$. (c) Slater's rules give values closer to the detailed calculations: Na, 2.51; K, 3.49. (d) Both approximations give the same value of Z_{eff} for Na and K; neither accounts for the gradual increase in Z_{eff} moving down a group. (e) Following the trend from detailed calculations, we predict a Z_{eff} value of approximately 4.5. **7.15** The $n = 3$ electrons in Kr experience a greater effective nuclear charge and thus have a greater probability of being closer to the nucleus. **7.17** (a) Atomic radii are determined by measuring distances between atoms in various situations. (b) Bonding radii are calculated from the internuclear separation of two atoms joined by a covalent chemical bond. Nonbonding radii are calculated from the internuclear separation between two gaseous atoms that collide and move apart but do not bond. (c) For a given element, the nonbonding radius is always larger than the bonding radius. (d) If a free atom reacts to become part of a covalent molecule, its radius changes from nonbonding to bonding and the atom gets smaller. **7.19** (a) 1.37 Å (b) The distance between W atoms will decrease. **7.21** From the sum of the atomic radii, $As-I = 2.52$ Å. This is very close to the experimental value of 2.55 Å. **7.23** (a) Decrease (b) increase (c) $O < Si < Ge < I$ **7.25** (a) $Cs > K > Li$ (b) $Pb > Sn > Si$ (c) $N > O > F$ **7.27** (a) False (b) true (c) false **7.29** The red sphere is a metal; its size decreases on reaction, characteristic of the change in radius when a metal atom forms a cation. The blue sphere is a nonmetal; its size increases on reaction, characteristic of the change in radius when a nonmetal atom forms an anion. **7.31** (a) An isoelectronic series is a group of atoms or ions that have the same number of electrons and the same electron configuration. (b) Ga^{3+} : Ar; Zr^{4+} : Kr; Mn^{7+} : Ar; I^- : Xe; Pb^{2+} : Hg **7.33** (a) Ar (b) Ar (c) There is no neutral atom isoelectronic with Fe^{2+} . Because transition metals fill the s subshell first but

also lose s electrons first when they form ions, many transition metal ions do not have isoelectronic neutral atoms. (d) No isoelectronic neutral atom; same reason as part (c). (e) No isoelectronic neutral atom; same reason as part (c). **7.35** (a) K^+ is smaller. (b) Cl^- , $Z_{\text{eff}} = 7$; K^+ , $Z_{\text{eff}} = 9$ (c) Cl^- : $Z_{\text{eff}} = 5.75$; K^+ , $Z_{\text{eff}} = 7.75$ (d) For isoelectronic ions, as nuclear charge (Z) increases, effective nuclear charge (Z_{eff}) increases and ionic radius decreases. **7.37** (a) $Se < Se^{2-} < Te^{2-}$ (b) $Co^{3+} < Fe^{3+} < Fe^{2+}$ (c) $Ti^{4+} < Sc^{3+} < Ca$ (d) $Be^{2+} < Na^+ < Ne$ **7.39** $Al(g) \rightarrow Al^+(g) + e^-$; $Al^+(g) \rightarrow Al^{2+}(g) + e^-$; $Al^{2+}(g) \rightarrow Al^{3+}(g) + e^-$. The process for the first ionization energy requires the least amount of energy. **7.41** (a) False. Ionization energies are always positive quantities. (b) False. F has a greater first ionization energy than O. (c) True. **7.43** (a) The smaller the atom, the larger its first ionization energy. (b) Of the nonradioactive elements, He has the largest and Cs the smallest first ionization energy. **7.45** (a) Cl (b) Ca (c) K (d) Ge (e) Sn **7.47** (a) Fe^{2+} , $[Ar]3d^6$ (b) Hg^{2+} , $[Xe]4f^{14}5d^{10}$ (c) Mn^{2+} , $[Ar]3d^5$ (d) Pt^{2+} , $[Xe]4f^{14}5d^8$ (e) P^{3-} , $[Ne]3s^23p^6$ **7.49** Ni^{2+} , $[Ar]3d^8$; Pd^{2+} , $[Kr]4d^8$; Pt^{2+} , $[Xe]4f^{14}5d^8$ **7.51** (a) Positive, endothermic, values for ionization energy and electron affinity mean that energy is required to either remove or add electrons. Valence electrons in Ar experience the largest Z_{eff} of any element in the third row, resulting in a large, positive ionization energy. When an electron is added to Ar, the $n = 3$ electrons become core electrons that screen the extra electron so effectively that Ar^- has a higher energy than an Ar atom and a free electron. This results in a large positive electron affinity. (b) kJ/mol **7.53** Electron affinity of Br: $Br(g) + 1e^- \rightarrow Br^-(g)$; $[Ar]4s^23d^{10}4p^5 \rightarrow [Ar]4s^23d^{10}4p^6$; electron affinity of Kr: $Kr(g) + 1e^- \rightarrow Kr^-(g)$; $[Ar]4s^23d^{10}4p^6 \rightarrow [Ar]4s^23d^{10}4p^65s^1$. Br^- adopts the stable electron configuration of Kr; the added electron experiences essentially the same Z_{eff} and stabilization as the other valence electrons and electron affinity is negative. In Kr^- ion, the added electron occupies the higher energy $5s$ orbital. A $5s$ electron is farther from the nucleus, effectively shielded by the spherical Kr core and not stabilized by the nucleus; electron affinity is positive. **7.55** (a) Ionization energy (I_1) of Ne: $Ne(g) \rightarrow Ne^+(g) + 1e^-$; $[He]2s^22p^6 \rightarrow [He]2s^22p^5$; electron affinity (E_1) of F: $F(g) + 1e^- \rightarrow F^-(g)$; $[He]2s^22p^5 \rightarrow [He]2s^22p^6$. (b) I_1 of Ne is positive; E_1 of F is negative. (c) One process is apparently the reverse of the other, with one important difference. Ne has a greater Z and Z_{eff} , so we expect I_1 for Ne to be somewhat greater in magnitude and opposite in sign to E_1 for F. **7.57** The smaller the first ionization energy of an element, the greater the metallic character of that element. **7.59** Agree. When forming ions, all metals form cations. The only nonmetallic element that forms cations is the metalloid Sb, which is likely to have significant metallic character. **7.61** Ionic: SnO_2 , Al_2O_3 , Li_2O , Fe_2O_3 ; molecular: CO_2 , H_2O . Ionic compounds are formed by combining a metal and a nonmetal; molecular compounds are formed by two or more nonmetals. **7.63** (a) An *acidic oxide* dissolved in water produces an acidic solution; a *basic oxide* dissolved in water produces a basic solution. (b) Oxides of nonmetals, such as SO_3 , are acidic; oxides of metals, such as CaO , are basic. **7.65** (a) Dichlorineheptoxide (b) $2Cl_2(g) + 7O_2(g) \rightarrow 2Cl_2O_7(l)$ (c) While most nonmetal oxides we have seen, such as CO_2 or SO_2 , are gases, a boiling point of $81^\circ C$ is expected for a large molecule like Cl_2O_7 . (d) Cl_2O_7 is an acidic oxide, so it will be more reactive to base, OH^- . (e) The oxidation state of Cl in Cl_2O_7 is +7; the corresponding electron configuration for Cl is $[He]2s^22p^6$ or $[Ne]$. **7.67** (a) $BaO(s) + H_2O(l) \rightarrow Ba(OH)_2(aq)$ (b) $FeO(s) + 2HClO_4(aq) \rightarrow Fe(ClO_4)_2(aq) + H_2O(l)$ (c) $SO_3(g) + H_2O(l) \rightarrow H_2SO_4(aq)$ (d) $CO_2(g) + 2NaOH(aq) \rightarrow Na_2CO_3(aq) + H_2O(l)$ **7.69** Yes, the reactivity of a metal correlates with its first ionization energy. Since metals lose electrons when they form ions, the less energy required for this process, the more reactive the metal. However, we usually observe reactivity of metals in the solid state and ionization energy is a gas phase property, so there are differences between the two properties. **7.71** (a) Ca is more reactive because it has a lower ionization energy than Mg. (b) K is more reactive because it has a lower ionization energy than Ca. **7.73** (a) $2K(s) + Cl_2(g) \rightarrow 2KCl(s)$ (b) $SrO(s) + H_2O(l) \rightarrow Sr(OH)_2(aq)$ (c) $4Li(s) + O_2(g) \rightarrow 2Li_2O(s)$ (d) $2Na(s) + S(l) \rightarrow Na_2S(s)$ **7.75** (a) Both classes of reaction are redox

reactions where either hydrogen or the halogen gains electrons and is reduced. The product is an ionic solid, where either hydride ion, H^- , or a halide ion, X^- , is the anion. (b) $\text{Ca}(s) + \text{F}_2(g) \longrightarrow \text{CaF}_2(s)$; $\text{Ca}(s) + \text{H}_2(g) \longrightarrow \text{CaH}_2(s)$. Both products are ionic solids containing Ca^{2+} and the corresponding anion in a 1:2 ratio. **7.77** (a) Br, $[\text{Ar}]4s^24p^5$; Cl, $[\text{Ne}]3s^23p^5$ (b) Br and Cl are in the same group, and both adopt a $1-$ ionic charge. (c) The ionization energy of Br is smaller than that of Cl, because the $4p$ valence electrons in Br are farther from the nucleus and less tightly held than the $3p$ electrons of Cl. (d) Both react slowly with water to form $\text{HX} + \text{HOX}$. (e) The electron affinity of Br is less negative than that of Cl, because the electron added to the $4p$ orbital in Br is farther from the nucleus and less tightly held than the electron added to the $3p$ orbital of Cl. (f) The atomic radius of Br is larger than that of Cl, because the $4p$ valence electrons in Br are farther from the nucleus and less tightly held than the $3p$ electrons of Cl. **7.79** (a) The term *inert* was dropped because it no longer described all the Group 8A elements. (b) In the 1960s, scientists discovered that Xe would react with substances having a strong tendency to remove electrons, such as F_2 . Thus, Xe could not be categorized as an “inert” gas. (c) The group is now called the noble gases. **7.81** (a) $2\text{O}_3(g) \longrightarrow 3\text{O}_2(g)$ (b) $\text{Xe}(g) + \text{F}_2(g) \longrightarrow \text{XeF}_2(g)$; $\text{Xe}(g) + 2\text{F}_2(g) \longrightarrow \text{XeF}_4(s)$; $\text{Xe}(g) + 3\text{F}_2(g) \longrightarrow \text{XeF}_6(s)$ (c) $\text{S}(s) + (\text{d}) 2\text{F}_2(g) + 2\text{H}_2\text{O}(l) \longrightarrow 4\text{HF}(aq) + \text{O}_2(g)$ **7.83** Up to $Z = 82$, there are three instances where atomic weights are reversed relative to atomic numbers: Ar and K; Co and Ni; Te and I. In each case the most abundant isotope of the element with the larger atomic number has one more proton but fewer neutrons than the element with the smaller atomic number. The smaller number of neutrons causes the element with the larger Z to have a smaller than expected atomic weight. **7.85** (a) $5+$ (b) $4.8+$ (c) Shielding is greater for $3p$ electrons, owing to penetration by $3s$ electrons, so Z_{eff} for $3p$ electrons is less than that for $3s$ electrons. (d) The first electron lost is a $3p$ electron because it has a smaller Z_{eff} and experiences less attraction for the nucleus than a $3s$ electron does. **7.88** (a) The estimated distances are a bit longer than the measured distances. This probably shows a systematic bias in either the estimated radii or in the method of obtaining the measured values. (b) The principal quantum number of the outer electrons and thus the average distance of these electrons from the nucleus increase from P($n = 3$) to As($n = 4$) to Sb($n = 5$). This causes the systematic increase in M–H distance. **7.92** (a) $2\text{Sr}(s) + \text{O}_2(g) \longrightarrow 2\text{SrO}(s)$ (b) Based on ionic radii, the length of the side of the cube is 5.16 \AA . (c) There are four SrO units in the cube.

(b) O^{3-} , $[\text{Ne}]3s^1$. The third electron would be added to the $3s$ orbital, which is farther from the nucleus and more strongly shielded by the $[\text{Ne}]$ core. The overall attraction of this $3s$ electron for the oxygen nucleus is not large enough for O^{3-} to be a stable particle. **7.98** (a) For both H and the alkali metals, the added electron will complete an ns subshell, so shielding and repulsion effects will be similar. For the halogens, the electron is added to an np subshell, so the energy change is likely to be quite different. (b) True. The electron configuration of H is $1s^1$. The single $1s$ electron experiences no repulsion from other electrons and feels the full unshielded nuclear charge. The outer electrons of all other elements that form compounds are shielded by a spherical inner core of electrons and are less strongly attracted to the nucleus, resulting in larger bonding atomic radii. (c) Both H and the halogens have large ionization energies. The relatively large effective nuclear charge experienced by np electrons of the halogens is similar to the unshielded nuclear charge experienced by the H $1s$ electron. For the alkali metals, the ns electron being removed is effectively shielded by the core electrons, so ionization energies are low. (d) ionization energy of hydride, $\text{H}^-(g) \longrightarrow \text{H}(g) + 1e^-$ (e) electron affinity of hydrogen, $\text{H}(g) + 1e^- \longrightarrow \text{H}^-(g)$. The value for the ionization energy of hydride is equal in magnitude but opposite in sign to the electron affinity of hydrogen. **7.103** Electron configuration, $[\text{Rn}]7s^25f^46d^{10}7p^5$; first

ionization energy, 805 kJ/mol ; electron affinity, -235 kJ/mol ; atomic size, 1.65 \AA ; common oxidation state, -1 **7.106** (a) Li, $[\text{He}]2s^1$; $Z_{\text{eff}} \approx 1+$ (b) $I_1 \approx 5.45 \times 10^{-19} \text{ J/mol} \approx 328 \text{ kJ/mol}$ (c) The estimated value of 328 kJ/mol is less than the Table 7.4 value of 520 kJ/mol . Our estimate for Z_{eff} was a lower limit; the $[\text{He}]$ core electrons do not perfectly shield the $2s$ electron from the nuclear charge. (d) Based on the experimental ionization energy, $Z_{\text{eff}} = 1.26$. This value is greater than the estimate from part (a) but agrees well with the “Slater” value of 1.3 and is consistent with the explanation in part (c). **7.108** (a) 9.8902 \AA . (b) For Hg, the first ionization energy is 1007 kJ/mol , while the XPS energy of the $4f$ electron is $10,100 \text{ kJ/mol}$. The energy required to remove a $4f$ core electron is 10 times the energy required to remove a $6s$ valence electron. For O, the first ionization energy is 1314 kJ/mol , while the XPS energy of a $1s$ electron is $51,200 \text{ kJ/mol}$. The energy required to remove a $1s$ core electron is 40 times that required to remove a $2p$ valence electron. (c) Hg^{2+} , $[\text{Xe}]4f^{14}5d^{10}$; valence electrons are $5d$. O^{2-} , $[\text{He}]2s^22p^6$ or $[\text{Ne}]$; valence electrons are $2p$ (d) $\text{Hg}^{2+}5d$, $Z_{\text{eff}} = 18.85$; $\text{Hg}^{2+}4f$, $Z_{\text{eff}} = 43.85$; $\text{O}^{2-}4f$, $Z_{\text{eff}} = 3.85$. **7.110** (a) Mg_3N_2 (b) $\text{Mg}_3\text{N}_2(s) + 3\text{H}_2\text{O}(l) \longrightarrow 3\text{MgO}(s) + 2\text{NH}_3(g)$; the driving force is the production of $\text{NH}_3(g)$. (c) $17\% \text{ Mg}_3\text{N}_2$ (d) $3\text{Mg}(s) + 2\text{NH}_3(g) \longrightarrow \text{Mg}_3\text{N}_2(s) + 3\text{H}_2(g)$. NH_3 is the limiting reactant and 0.46 g H_2 is formed. (e) $\Delta H_{\text{rxn}}^\circ = -368.70 \text{ kJ}$

CHAPTER 8

8.1 (a) Group 4A or 14 (b) Group 2A or 2 (c) Group 5A or 15 **8.4** (a) Ru (b) $[\text{Kr}]5s^24d^6$. **8.7** (a) Moving from left to right along the molecule, the first C needs 2 H atoms, the second needs 1, the third needs none, and the fourth needs 1. (b) In order of increasing bond length: $3 < 1 < 2$ (c) In order of increasing bond enthalpy: $2 < 1 < 3$ **8.9** (a) Valence electrons are those that take part in chemical bonding. This usually means the electrons beyond the core noble-gas configuration of the atom, although it is sometimes only the outer-shell electrons. (b) A nitrogen atom has 5 valence electrons. (c) The atom (Si) has 4 valence electrons. **8.11** Si, $1s^22s^22p^63s^23p^2$. The $n = 3$ electrons are valence electrons; the others are nonvalence electrons. Valence electrons participate in chemical bonding; the others do not.

8.17 (a) AlF_3 (b) K_2S (c) Y_2O_3 (d) Mg_3N_2 **8.19** (a) Sr^{2+} , $[\text{Ar}]4s^23d^{10}4p^6 = [\text{Kr}]$, noble-gas configuration (b) Ti^{2+} , $[\text{Ar}]3d^2$ (c) Se^{2-} , $[\text{Ar}]4s^23d^{10}4p^6 = [\text{Kr}]$, noble-gas configuration (d) Ni^{2+} , $[\text{Ar}]3d^8$ (e) Br^- , $[\text{Ar}]4s^23d^{10}4p^6 = [\text{Kr}]$, noble-gas configuration (f) Mn^{3+} , $[\text{Ar}]3d^4$ **8.21** (a) *Lattice energy* is the energy required to totally separate one mole of solid ionic compound into its gaseous ions. (b) The magnitude of the lattice energy depends on the magnitudes of the charges of the two ions, their radii, and the arrangement of ions in the lattice. **8.23** KF, 808 kJ/mol ; CaO, 3414 kJ/mol ; ScN, 7547 kJ/mol . The interionic distances in the three compounds are similar. For compounds with similar ionic separations, the lattice energies should be related as the product of the charges of the ions. The lattice energies above are approximately related as $1 : 4 : 9$. Slight variations are due to the small differences in ionic separations. **8.25** Since the ionic charges are the same in the two compounds, the K—Br and Cs—Cl separations must be approximately equal. **8.27** The large attractive energy between oppositely charged Ca^{2+} and O^{2-} more than compensates for the energy required to form Ca^{2+} and O^{2-} from the neutral atoms. **8.29** The lattice energy of $\text{RbCl}(s)$ is $+692 \text{ kJ/mol}$. This value is smaller than the lattice energy for NaCl because Rb^+ has a larger ionic radius than Na^+ and therefore cannot approach Cl^- as closely as Na^+ can. **8.31** (a) A *covalent bond* is the bond formed when two atoms share one or more pairs of electrons. (b) Any simple compound whose component atoms are nonmetals, such as H_2 , SO_2 , and CCl_4 , are molecular and have covalent bonds between atoms. (c) Covalent, because it is a gas at room temperature and below.

8.33

8.35 (a) $\ddot{\text{O}}=\ddot{\text{O}}$ (b) A double bond is required because there are not enough electrons to satisfy the octet rule with single bonds and unshared pairs. (c) The greater the number of shared electron pairs between two atoms, the shorter the distance between the atoms. An $\text{O}=\text{O}$ double bond is shorter than an $\text{O}-\text{O}$ single bond. 8.37 (a) *Electronegativity* is the ability of an atom in a molecule to attract electrons to itself. (b) The range of electronegativities on the Pauling scale is 0.7–4.0. (c) Fluorine is the most electronegative element. (d) Cesium is the least electronegative element that is not radioactive. 8.39 (a) Mg (b) S (c) C (d) As 8.41 The bonds in (a), (c), and (d) are polar. The more electronegative element in each polar bond is (a) F (c) O (d) I. 8.43 (a) The calculated charge on H and Br is $0.12e$. (b) From Sample Exercise 8.5, the calculated charge on H and Cl in HCl is $0.178e$. HBr has a smaller dipole moment and longer bond length than HCl; these properties both contribute to the smaller charge separation in HBr. 8.45 (a) SiCl_4 , molecular, silicon tetrachloride; LaF_3 , ionic, lanthanum(III) fluoride (b) FeCl_2 , ionic, iron(II) chloride; ReCl_6 , molecular (metal in high oxidation state), rhenium hexachloride. (c) PbCl_4 , molecular (by contrast to the distinctly ionic RbCl), lead tetrachloride; RbCl , ionic, rubidium chloride

8.49 (a) *Formal charge* is the charge on each atom in a molecule, assuming all atoms have the same electronegativity. (b) Formal charges are not actual charges. They are a bookkeeping system that assumes perfect covalency, one extreme for the possible electron distribution in a molecule. (c) Oxidation numbers are a bookkeeping system that assumes the more electronegative element holds all electrons in a bond. The true electron distribution is some composite of the two extremes. 8.51 Formal charges are shown on the Lewis structures; oxidation numbers are listed below each structure.

(b) O_3 is isoelectronic with NO_2^- ; both have 18 valence electrons. (c) Since each $\text{N}-\text{O}$ bond has partial double-bond character, the $\text{N}-\text{O}$ bond length in NO_2^- should be shorter than an $\text{N}-\text{O}$ single bond. 8.55 The more electron pairs shared by two atoms, the shorter

the bond. Thus, the $\text{C}-\text{O}$ bond lengths vary in the order $\text{CO} < \text{CO}_2 < \text{CO}_3^{2-}$. 8.57 (a) Two equally valid Lewis structures can be drawn for benzene.

The concept of resonance dictates that the true description of bonding is some hybrid or blend of these two Lewis structures. The most obvious blend of these two resonance structures is a molecule with six equivalent $\text{C}-\text{C}$ bonds with equal lengths. (b) This model predicts a uniform $\text{C}-\text{C}$ bond length that is shorter than a single bond but longer than a double bond. 8.59 (a) The octet rule states that atoms will gain, lose, or share electrons until they are surrounded by eight valence electrons. (b) The octet rule applies to atoms in a covalent compound and the individual ions in an ionic compound. In the ionic compound CCl_4 , the atoms share electrons in order to surround themselves with an octet. In the ionic compound MgCl_2 , Mg loses $2e^-$ to become Mg^{2+} with the electron configuration of Ne. Each Cl atom gains one electron to form Cl^- with the electron configuration of Ar. 8.61 No chlorine oxide will obey the octet rule. Chlorine has seven valence electrons, and oxygen has six. For neutral chlorine oxides, regardless of the number of oxygen atoms in the molecule, the total number of valence electrons will be an (odd + even) sum, which is always an odd number. 8.63

Other resonance structures that minimize formal charges but violate the octet rule can be drawn. The octet rule versus formal charge debate is ongoing.

6 electrons around Al

10 electrons around Sb

This structure violates the octet rule.

(c) Formal charges are minimized on the structure that violates the octet rule; this form is probably dominant. 8.67 Three resonance structures for HSO_3^- are shown here. Because the ion has a $1-$ charge, the sum of the formal charges of the atoms is -1 .

The structure with no double bonds obeys the octet rule for all atoms, but does not lead to minimized formal charges. The structures with one and two double bonds both minimize formal charge but do not obey the octet rule. Of these two, the structure with one double bond is preferred because the formal charge is localized on the more electronegative oxygen atom.

8.69 (a) $\Delta H = -304$ kJ (b) $\Delta H = -82$ kJ (c) $\Delta H = -467$ kJ
8.71 (a) $\Delta H = -321$ kJ (b) $\Delta H = -103$ kJ (c) $\Delta H = -203$ kJ
8.73 (a) -97 kJ; exothermic (b) The ΔH calculated from bond enthalpies (-97 kJ) is slightly more exothermic (more negative) than that obtained using ΔH_f° values (-92.38 kJ). **8.75** The average Ti—Cl bond enthalpy is 430 kJ/mol. **8.77** (a) Six (nonradioactive) elements. Yes, they are in the same family, assuming H is placed with the alkali metals. The Lewis symbol represents the number of valence electrons of an element, and all elements in the same family have the same number of valence electrons. By definition of a family, all elements with the same Lewis symbol must be in the same family. **8.81** The charge on M is likely to be $3+$. The range of lattice energies for ionic compounds with the general formula MX and a charge of $2+$ on the metal is $3\text{--}4 \times 10^3$ kJ/mol. The lattice energy of 6×10^3 kJ/mol indicates that the charge on M must be greater than $2+$. **8.85** (a) B—O. The most polar bond will be formed by the two elements with the greatest difference in electronegativity. (b) Te—I. These elements have the two largest covalent radii among this group. (c) TeI₂. The octet rule is satisfied for all three atoms. (d) P₂O₃. Each P atom needs to share $3e^-$ and each O atom $2e^-$ to achieve an octet. And B₂O₃. Although this is not a purely ionic compound, it can be understood in terms of gaining and losing electrons to achieve a noble-gas configuration. If each B atom were to lose $3e^-$ and each O atom were to gain $2e^-$, charge balance and the octet rule would be satisfied. **8.90** (a) $+1$ (b) -1 (c) $+1$ (assuming the odd electron is on N) (d) 0 (e) $+3$ **8.95** An experimentally determined molecular structure will reveal bond lengths and angles of the B—A=B molecule. If resonance structures are important, the two B—A bond lengths will be identical. If the molecule features one single and one double bond, the lengths will be significantly different. **8.98** (a) $\Delta H = 7.85$ kJ/g nitroglycerine (b) $4\text{C}_7\text{H}_5\text{N}_3\text{O}_6(\text{s}) \rightarrow 6\text{N}_2(\text{g}) + 7\text{CO}_2(\text{g}) + 10\text{H}_2\text{O}(\text{g}) + 21\text{C}(\text{s})$
8.101 (a) Ti²⁺, [Ar]3d²; Ca, [Ar]4s². Yes. The 2 valence electrons in Ti²⁺ and Ca are in different principal quantum levels and different subshells. (b) In Ca the 4s is lower in energy than the 3d, while in Ti²⁺ the 3d is lower in energy than the 4s. (c) No. There is only one 4s orbital, so the 2 valence electrons in Ca are paired; there are 5 degenerate 3d orbitals, so the 2 valence electrons in Ti²⁺ are unpaired. **8.107** (a) Azide ion is N₃⁻. (b) Resonance structures with formal charges are shown.

(c) The structure with two double bonds minimizes formal charges and is probably the main contributor. (d) The N—N distances will be equal and have the approximate length of a N—N double bond, 1.24 Å. **8.112** (a) D(Br—Br)(l) = 223.6 kJ; D(Br—Br)(g) = 193 kJ (b) D(C—Cl)(l) = 336.1 kJ; D(C—Cl)(g) = 328 kJ (c) D(O—O)(l) = 192.7 kJ; D(O—O)(g) = 146 kJ (d) Breaking bonds in the liquid requires more energy than breaking bonds in the gas phase. Bond dissociation in the liquid phase can be thought of in two steps, vaporization of the liquid followed by bond dissociation in the gas phase. The greater bond dissociation enthalpy in the liquid phase is due to the contribution from the enthalpy of vaporization.

CHAPTER 9

9.1 Removing an atom from the equatorial plane of the trigonal bipyramid in Figure 9.3 creates a seesaw shape. **9.3** (a) 2 electron-domain geometries, linear and trigonal bipyramidal (b) 1 electron-domain

geometry, trigonal bipyramidal (c) 1 electron-domain geometry, octahedral (c) 1 electron-domain geometry, octahedral (d) 1 electron domain geometry, octahedral (e) 1 electron domain geometry, octahedral (f) 1 electron-domain geometry, trigonal bipyramidal (This triangular pyramid is an unusual molecular geometry not listed in Table 9.3. It could occur if the equatorial substituents on the trigonal bipyramid were extremely bulky, causing the nonbonding electron pair to occupy an axial position.) **9.5** (a) Zero energy corresponds to two separate, noninteracting Cl atoms. This infinite Cl—Cl distance is beyond the right extreme of the horizontal axis on the diagram. (b) According to the valence bond model, valence orbitals on the approaching atoms overlap, allowing two electrons to mutually occupy space between the two nuclei and be stabilized by two nuclei rather than one. (c) The Cl—Cl distance at the energy minimum on the plot is the Cl—Cl bond length. (d) At interatomic separations shorter than the bond distance, the two nuclei begin to repel each other, increasing the overall energy of the system. (e) The y -coordinate of the minimum point on the plot is a good estimate of the Cl—Cl bond energy or bond strength. **9.6** SiCl₄, 109° ; PF₃, 107° ; SF₂, 105° . Each molecule has tetrahedral electron domain geometry, but the number of nonbonding electron pairs increases from 0 to 2, respectively. Because nonbonding electron pairs occupy more space than bonding pairs, we expect the bond angles to decrease in the series. **9.9** (a) i, Two s atomic orbitals; ii, two p atomic orbitals overlapping end to end; iii, two p atomic orbitals overlapping side to side (b) i, σ -type MO; ii, σ -type MO; iii, π -type MO (c) i, antibonding; ii, bonding; iii, antibonding (d) i, the nodal plane is between the atom centers, perpendicular to the interatomic axis and equidistant from each atom. ii, there are two nodal planes; both are perpendicular to the interatomic axis. One is left of the left atom and the second is right of the right atom. iii, there are two nodal planes; one is between the atom centers, perpendicular to the interatomic axis and equidistant from each atom. The second contains the interatomic axis and is perpendicular to the first. **9.11** (a) Yes. The stated shape defines the bond angle and the bond length tells the size. (b) No. Atom A could have 2, 3, or 4 nonbonding electron pairs. **9.13** A molecule with tetrahedral molecular geometry has an atom at each vertex of the tetrahedron. A trigonal-pyramidal molecule has one vertex of the tetrahedron occupied by a nonbonding electron pair rather than an atom. **9.15** (a) An *electron domain* is a region in a molecule where electrons are most likely to be found. (b) Like the balloons in Figure 9.5, each electron domain occupies a finite volume of space, so they also adopt an arrangement where repulsions are minimized. **9.17** (a) The number of electron domains in a molecule or ion is the number of bonds (double and triple bonds count as one domain) plus the number of nonbonding electron pairs. (b) A *bonding electron domain* is a region between two bonded atoms that contains one or more pairs of bonding electrons. A *nonbonding electron domain* is localized on a single atom and contains one pair of nonbonding electrons. **9.19** (a) No effect on molecular shape (b) 1 nonbonding pair on P influences molecular shape (c) no effect (d) no effect (e) 1 nonbonding pair on S influences molecular shape **9.21** (a) 2 (b) 1 (c) none (d) 3 **9.23** The electron-domain geometry indicated by VSEPR describes the arrangement of all bonding and nonbonding electron domains. The molecular geometry describes just the atomic positions. In H₂O there are 4 electron domains around oxygen, so the electron-domain geometry is tetrahedral. Because there are 2 bonding and 2 nonbonding domains, the molecular geometry is bent. We make this distinction because all electron domains must be considered when describing the atomic arrangement and bond angles in a molecule but the molecular geometry or shape is a description of just the atom positions. **9.25** (a) Tetrahedral, tetrahedral (b) trigonal bipyramidal, T-shaped (c) octahedral, square pyramidal (d) octahedral, square planar **9.27** (a) Linear, linear (b) tetrahedral, trigonal pyramidal (c) trigonal bipyramidal, seesaw (d) octahedral, octahedral (e) tetrahedral, tetrahedral (f) linear, linear **9.29** (a) i, trigonal planar; ii, tetrahedral; iii, trigonal bipyramidal (b) i, 0; ii, 1; iii, 2 (c) N and P (d) Cl (or Br or I). This T-shaped molecular geometry arises from a trigonal-bipyramidal electron-domain geometry with 2 nonbonding domains. Assuming each F atom has 3 nonbonding domains and forms only single bonds with A, A must have 7 valence electrons and be in or below the third row of the periodic table

to produce these electron-domain and molecular geometries. **9.31** (a) 1–109°, 2–109° (b) 3–109°, 4–109° (c) 5–180° (d) 6–120°, 7–109°, 8–109° **9.33** The two molecules with trigonal-bipyramidal electron-domain geometry, PF₅ and SF₆, have more than one F—A—F bond angle. **9.35** (a) Although both ions have 4 bonding electron domains, the 6 total domains around Br require octahedral domain geometry and square-planar molecular geometry, while the 4 total domains about B lead to tetrahedral domain and molecular geometry. (b) The less electronegative the central atom, the larger the non-bonding electron domain, and the greater the effect of repulsive forces on adjacent bonding domains. The less electronegative the central atom, the greater the deviation from ideal tetrahedral angles. The angles will vary as H₂O > H₂S > H₂Se. **9.37** A bond dipole is the asymmetric charge distribution between two bonded atoms with unequal electronegativities. A molecular dipole moment is the three-dimensional sum of all the bond dipoles in a molecule. **9.39** (a) Yes. The net dipole moment vector points along the Cl—S—Cl angle bisector. (b) No, BeCl₂ does not have a dipole moment. **9.41** (a) In Exercise 9.29, molecules (ii) and (iii) will have nonzero dipole moments. Molecule (i) has no nonbonding electron pairs on A, and the 3 A—F bond dipoles are oriented so that they cancel. Molecules (ii) and (iii) have nonbonding electron pairs on A and their bond dipoles do not cancel. (b) In Exercise 9.30, molecules (i) and (ii) have a zero dipole moment. **9.43** (a) IF (d) PCl₃ and (f) IF₅ are polar.

9.45 (a) Lewis structures

Molecular geometries

(b) The middle isomer has a zero net dipole moment. (c) C₂H₃Cl has only one isomer, and it has a dipole moment. **9.47** (a) *Orbital overlap* occurs when valence atomic orbitals on two adjacent atoms share the same region of space. (b) A chemical bond is a concentration of electron density between the nuclei of two atoms. This concentration can take place because orbitals on the two atoms overlap. **9.49** (a) H—Mg—H, linear electron domain and molecular geometry (b) The linear electron-domain geometry in MgH₂ requires *sp* hybridization.

9.51

Molecule	Electron-Domain Geometry	Hybridization of Central Atom	Dipole Moment? Yes or No
CO ₂	Linear	<i>sp</i>	No
NH ₃	Tetrahedral	<i>sp</i> ³	Yes
CH ₄	Tetrahedral	<i>sp</i> ³	No
BH ₃	Trigonal planar	<i>sp</i> ²	No
SF ₄	Trigonal bipyramidal	Not applicable	Yes
SF ₆	Octahedral	Not applicable	No
H ₂ CO	Trigonal planar	<i>sp</i> ²	Yes
PF ₅	Trigonal bipyramidal	Not applicable	No
XeF ₂	Trigonal bipyramidal	Not applicable	No

9.53 (a) B, [He]2s²2p¹. One 2s electron is “promoted” to an empty 2p orbital. The 2s and two 2p orbitals that each contain one electron are

hybridized to form three equivalent hybrid orbitals in a trigonal-planar arrangement. (b) *sp*² (d) A single 2p orbital is unhybridized. It lies perpendicular to the trigonal plane of the *sp*² hybrid orbitals. **9.55** (a) *sp*² (b) *sp*³ (c) *sp* (d) *sp*³ **9.57** No hybrid orbitals discussed in this chapter form angles of 90° with each other; p atomic orbitals are perpendicular to each other. 109.5°, *sp*³; 120°, *sp*²

(c) A σ bond is generally stronger than a π bond because there is more extensive orbital overlap. (d) No. Overlap of two s orbitals results in electron density along the internuclear axis, while a π bond has none.

(b) *sp*³, *sp*², *sp* (c) nonplanar, planar, planar (d) 7 σ , 0 π ; 5 σ , 1 π ; 3 σ , 2 π (e) The Si analogs would have the same hybridization as the C compounds given in part (b). That Si is in the row below C means it has a larger bonding atomic radius and atomic orbitals than C. The close approach of Si atoms required to form strong, stable π bonds in Si₂H₄ and Si₂H₂ is not possible and these Si analogs do not readily form. **9.63** (a) 18 valence electrons (b) 16 valence electrons form σ bonds. (c) 2 valence electrons form π bonds. (d) No valence electrons are nonbonding. (e) The left and central C atoms are *sp*² hybridized; the right C atom is *sp*³ hybridized. **9.65** (a) ~109° about the leftmost C, *sp*³; ~120° about the right-hand C, *sp*² (b) The doubly bonded O can be viewed as *sp*², and the other as *sp*³; the nitrogen is *sp*³ with approximately 109° bond angles. (c) nine σ bonds, one π bond **9.67** (a) In a localized π bond, the electron density is concentrated between the two atoms forming the bond. In a delocalized π bond, the electron density is spread over all the atoms that contribute p orbitals to the network. (b) The existence of more than one resonance form is a good indication that a molecule will have delocalized π bonding. (c) delocalized

9.69 (a) Linear (b) The two central C atoms each have trigonal planar geometry with ~120° bond angles about them. The C and O atoms lie in a plane with the H atoms free to rotate in and out of this plane. (c) The molecule is planar with ~120° bond angles about the two N atoms. **9.71** (a) Hybrid orbitals are mixtures of atomic orbitals from a single atom and remain localized on that atom. Molecular orbitals are combinations of atomic orbitals from two or more atoms and are delocalized over at least two atoms. (b) Each MO can hold a maximum of two electrons. (c) Antibonding molecular orbitals can have electrons in them.

(b) There is one electron in H₂⁺. (c) σ_{1s}^1 (d) BO = $\frac{1}{2}$ (e) Fall apart. If the single electron in H₂⁺ is excited to the σ_{1s}^* orbital, its energy is higher than the energy of an H 1s atomic orbital and H₂⁺ will decompose into a hydrogen atom and a hydrogen ion.

9.75

(a) 1 σ bond (b) 2 π bonds (c) 1 σ^* and 2 π^* **9.77** (a) When comparing the same two bonded atoms, bond order and bond energy are

directly related, while bond order and bond length are inversely related. When comparing different bonded nuclei, there are no simple relationships. (b) Be_2 is not expected to exist; it has a bond order of zero and is not energetically favored over isolated Be atoms. Be_2^+ has a bond order of 0.5 and is slightly lower in energy than isolated Be atoms. It will probably exist under special experimental conditions.

9.79 (a, b) Substances with no unpaired electrons are weakly repelled by a magnetic field. This property is called *diamagnetism*. (c) O_2^{2-} , Be_2^{2+} **9.81** (a) B_2^+ , $\sigma_{2s}^2\sigma_{2s}^*\pi_{2p}^1$, increase (b) Li_2^+ , $\sigma_{1s}^2\sigma_{1s}^*\sigma_{2s}^1$, increase (c) N_2^+ , $\sigma_{2s}^2\sigma_{2s}^*\pi_{2p}^4\sigma_{2p}^1$, increase (d) Ne_2^{2+} , $\sigma_{2s}^2\sigma_{2s}^*\sigma_{2p}^2\pi_{2p}^4\pi_{2p}^4$, decrease **9.83** CN, $\sigma_{2s}^2\sigma_{2s}^*\sigma_{2p}^2\pi_{2p}^3$, bond order = 2.5; CN^+ , $\sigma_{2s}^2\sigma_{2s}^*\sigma_{2p}^2\pi_{2p}^2$, bond order = 2.0; CN^- , $\sigma_{2s}^2\sigma_{2s}^*\sigma_{2p}^2\pi_{2p}^4$, bond order = 3.0. (a) CN^- (b) CN, CN^+ **9.85** (a) $3s, 3p_x, 3p_y, 3p_z$ (b) π_{3p} (c) 2 (d) If the MO diagram for P_2 is similar to that of N_2 , P_2 will have no unpaired electrons and be diamagnetic. **9.89** SiF_4 is tetrahedral, SF_4 is seesaw, XeF_4 is square planar. The shapes are different because the number of nonbonding electron domains is different in each molecule, even though all have four bonding electron domains. Bond angles and thus molecular shape are determined by the total number of electron domains. **9.92** (a) 2 σ bonds, 2 π bonds (b) 3 σ bonds, 4 π bonds (c) 3 σ bonds, 1 π bond (d) 4 σ bonds, 1 π bond **9.94** BF_3 is trigonal planar, the B—F bond dipoles cancel and the molecule is nonpolar. PF_3 has a tetrahedral electron-domain geometry with one position occupied by a nonbonding electron pair. The nonbonding electron pair ensures an asymmetrical electron distribution and the molecule is polar. **9.99**

(a) The molecule is nonplanar. (b) Allene has no dipole moment. (c) The bonding in allene would not be described as delocalized. The π electron clouds of the two adjacent $\text{C}=\text{C}$ are mutually perpendicular, so there is no overlap and no delocalization of π electrons. **9.101** (a) All O atoms have sp^2 hybridization. (b) The two σ bonds are formed by overlap of sp^2 hybrid orbitals, the π bond is formed by overlap of atomic p orbitals, one nonbonded pair is in a p atomic orbital and the other five nonbonded pairs are in sp^2 hybrid orbitals. (c) unhybridized p atomic orbitals (d) four, two from the π bond and two from the nonbonded pair in the p atomic orbital **9.104** $\sigma_{2s}^2\sigma_{2s}^*\pi_{2p}^4\sigma_{2p}^1\pi_{2p}^*$ (a) Paramagnetic (b) The bond order of N_2 in the ground state is 3; in the first excited state it has a bond order of 2. Owing to the reduction in bond order, N_2 in the first excited state has a weaker N—N bond. **9.110** (a) $2\text{SF}_4(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 2\text{OSF}_4(\text{g})$

(c) $\Delta H = -551 \text{ kJ}$, exothermic (d) The electron-domain geometry is trigonal bipyramidal. The O atom can be either equatorial or axial. (e) Since F is more electronegative than O, the structure that minimizes $90^\circ \text{F}-\text{S}-\text{F}$ angles, the one with O axial, is preferred.

CHAPTER 10

10.1 It would be much easier to drink from a straw on Mars. When a straw is placed in a glass of liquid, the atmosphere exerts equal pressure inside and outside the straw. When we drink through a straw, we withdraw air, thereby reducing the pressure on the liquid inside. If only 0.007 atm is exerted on the liquid in the glass, a very small reduction in pressure inside the straw will cause the liquid to rise. **10.4** (a) As the reaction proceeds at constant temperature and pressure, the number of particles decreases and the container volume decreases. (b) As the reaction proceeds at constant volume and temperature, the number of particles decreases and pressure decreases. **10.7** (a) $P_{\text{red}} < P_{\text{yellow}} < P_{\text{blue}}$

(b) $P_{\text{red}} = 0.28 \text{ atm}$; $P_{\text{yellow}} = 0.42 \text{ atm}$; $P_{\text{blue}} = 0.70 \text{ atm}$ **10.10** (a) $P(\text{ii}) < P(\text{i}) = P(\text{iii})$ (b) $P_{\text{He}}(\text{iii}) < P_{\text{He}}(\text{ii}) < P_{\text{He}}(\text{i})$ (c) $d(\text{ii}) < d(\text{i}) < d(\text{iii})$ (d) The average kinetic energies of the particles in the three containers are equal. **10.13** (a) A gas is much less dense than a liquid. (b) A gas is much more compressible than a liquid. (c) All mixtures of gases are homogenous. Similar liquid molecules form homogeneous mixtures, while very dissimilar molecules form heterogeneous mixtures. (d) Both gases and liquids conform to the shape of their container. A gas also adopts the volume of its container, while a liquid maintains its own volume. **10.15** (a) $1.8 \times 10^3 \text{ kPa}$ (b) 18 atm (c) $2.6 \times 10^2 \text{ lb/in.}^2$ **10.17** (a) 10.3 m (b) 2.1 atm **10.19** (a) The tube can have any cross-sectional area. (b) At equilibrium the force of gravity per unit area acting on the mercury column is not equal to the force of gravity per unit area acting on the atmosphere. (c) The column of mercury is held up by the pressure of the atmosphere applied to the exterior pool of mercury. (d) If you took the mercury barometer with you on a trip from the beach to high mountains, the height of the mercury column would decrease with elevation. **10.21** (a) 0.349 atm (b) 265 mm Hg (c) $3.53 \times 10^4 \text{ Pa}$ (d) 0.353 bar (e) 5.13 psi **10.23** (a) $P = 773.4 \text{ torr}$ (b) $P = 1.018 \text{ atm}$ (c) The pressure in Chicago is greater than standard atmospheric pressure, and so it makes sense to classify this weather system as a “high-pressure system.” **10.25** (i) 0.31 atm (ii) 1.88 atm (iii) 0.136 atm **10.27** (a) If V decreases by a factor of 4, P increases by a factor of 4. (b) If T decreases by a factor of 2, P decreases by a factor of 2. (c) If n decreases by a factor of 4, P decreases by a factor of 4. **10.29** (a) If equal volumes of gases at the same temperature and pressure contain equal numbers of molecules and molecules react in the ratios of small whole numbers, it follows that the volumes of reacting gases are in the ratios of small whole numbers. (b) Since the two gases are at the same temperature and pressure, the ratio of the numbers of atoms is the same as the ratio of volumes. There are 1.5 times as many Xe atoms as Ne atoms. (c) Yes. By definition, one mole of an ideal gas contains Avogadro’s number of particles. At a given temperature and pressure, equal numbers of particles occupy the same volume, so one mole of an ideal gas will always occupy the same volume at the given temperature and pressure. **10.31** (a) An ideal gas exhibits pressure, volume, and temperature relationships described by the equation $PV = nRT$. (b) Boyle’s law, $V = \text{constant}/P$; Charles’s law, $V = \text{constant} \times T$; Avogadro’s law, $V = \text{constant} \times n$. Collect all the equalities: $V = (\text{constant} \times T \times n)/P$. Call the constant R and multiply both sides of the equation by P , $PV = nRT$. (c) $PV = nRT$; P in atmospheres, V in liters, n in moles, T in kelvins. (d) $R = 0.08315 \text{ L}\cdot\text{bar}/\text{mol}\cdot\text{K}$. **10.33** Flask A contains the gas with $\mathcal{M} = 30 \text{ g/mol}$, and flask B contains the gas with $\mathcal{M} = 60 \text{ g/mol}$.

10.35

P	V	n	T
2.00 atm	1.00 L	0.500 mol	48.7 K
0.300 atm	0.250 L	$3.05 \times 10^{-3} \text{ mol}$	27 °C
650 torr	11.2 L	0.333 mol	350 K
10.3 atm	585 mL	0.250 mol	295 K

10.37 $8.2 \times 10^2 \text{ kg He}$ **10.39** (a) 5.15×10^{22} molecules (b) 6.5 kg air **10.41** (a) 91 atm (b) $2.3 \times 10^2 \text{ L}$ **10.43** (a) 29.8 g Cl_2 (b) 9.42 L (c) 501 K (d) 2.28 atm **10.45** (a) $n = 2 \times 10^{-4} \text{ mol O}_2$ (b) The roach needs $8 \times 10^{-3} \text{ mol O}_2$ in 48 h, approximately 100% of the O_2 in the jar. **10.47** (a) $1.32 \times 10^7 \text{ L}$ (b) $5.1 \times 10^8 \text{ mol Hg}$ **10.49** For gas samples at the same conditions, molar mass determines density. Of the three gases listed, (c) Cl_2 has the largest molar mass. **10.51** (c) Because the helium atoms are of lower mass than the average air molecule, the helium gas is less dense than air. The balloon thus weighs less than the air displaced by its volume. **10.53** (a) $d = 1.77 \text{ g/L}$ (b) $\mathcal{M} = 80.1 \text{ g/mol}$ **10.55** $\mathcal{M} = 89.4 \text{ g/mol}$ **10.57** $4.1 \times 10^{-9} \text{ g Mg}$ **10.59** (a) 21.4 L CO_2 (b) 40.7 L O_2 **10.61** 0.402 g Zn **10.63** (a) When the stopcock is opened, the volume occupied by $\text{N}_2(\text{g})$ increases from 2.0 L to 5.0 L. $P_{\text{N}_2} = 0.40 \text{ atm}$ (b) When the gases mix, the volume of $\text{O}_2(\text{g})$ increases from 3.0 L to 5.0 L. $P_{\text{O}_2} = 1.2 \text{ atm}$ (c) $P_t = 1.6 \text{ atm}$

10.65 (a) $P_{\text{He}} = 1.87 \text{ atm}$, $P_{\text{Ne}} = 0.807 \text{ atm}$, $P_{\text{Ar}} = 0.269 \text{ atm}$, (b) $P_t = 2.95 \text{ atm}$ **10.67** $\chi_{\text{CO}_2} = 0.00039$ **10.69** $P_{\text{CO}_2} = 0.305 \text{ atm}$, $P_t = 1.232 \text{ atm}$ **10.71** $P_{\text{N}_2} = 1.3 \text{ atm}$, $P_{\text{O}_2} = 0.54 \text{ atm}$, $P_{\text{CO}_2} = 0.27 \text{ atm}$ **10.73** 2.5 mole % O_2 **10.75** $P_t = 2.47 \text{ atm}$ **10.77** (a) Increase in temperature at constant volume or decrease in volume or increase in pressure (b) decrease in temperature (c) increase in volume, decrease in pressure (d) increase in temperature **10.79** The fact that gases are readily compressible supports the assumption that most of the volume of a gas sample is empty space. **10.81** Average speed is the sum of the speeds of all particles divided by the total number of particles. The root mean square speed is the speed of a molecule with the same kinetic energy as the average kinetic energy of the sample. The root mean square speed is larger for a given gas sample at a fixed temperature, but the difference between the two is small. **10.83** (a) Average kinetic energy of the molecules increases. (b) Root mean square speed of the molecules increases. (c) Strength of an average impact with the container walls increases. (d) Total collisions of molecules with walls per second increases. **10.85** (a) In order of increasing speed and decreasing molar mass: $\text{HBr} < \text{NF}_3 < \text{SO}_2 < \text{CO} < \text{Ne}$ (b) $u_{\text{NF}_3} = 324 \text{ m/s}$ (c) The most probable speed of an ozone molecule in the stratosphere is 306 m/s. **10.87** Effusion is the escape of gas molecules through a tiny hole. Diffusion is the distribution of a gas throughout space or throughout another substance. **10.89** The order of increasing rate of effusion is ${}^2\text{H}^{37}\text{Cl} < {}^1\text{H}^{37}\text{Cl} < {}^2\text{H}^{35}\text{Cl} < {}^1\text{H}^{35}\text{Cl}$. **10.91** As_4S_6 **10.93** (a) Non-ideal-gas behavior is observed at very high pressures and low temperatures. (b) The real volumes of gas molecules and attractive intermolecular forces between molecules cause gases to behave nonideally. (c) According to the ideal-gas law, the ratio PV/RT should be constant for a given gas sample at all combinations of pressure, volume, and temperature. If this ratio changes with increasing pressure, the gas sample is not behaving ideally. **10.95** Ar ($a = 1.34$, $b = 0.0322$) will behave more like an ideal gas than CO_2 ($a = 3.59$, $b = 0.427$) at high pressures. **10.97** (a) $P = 4.89 \text{ atm}$ (b) $P = 4.69 \text{ atm}$ (c) Qualitatively, molecular attractions are more important as the amount of free space decreases and the number of molecular collisions increases. Molecular volume is a larger part of the total volume as the container volume decreases. **10.99** From the value of b for Xe, the nonbonding radius is 2.72 Å. From Figure 7.6, the bonding atomic radius of Xe is 1.30 Å. We expect the bonding radius of an atom to be smaller than its nonbonding radius, but this difference is quite large. **10.101** $V = 3.1 \text{ mm}^3$ **10.105** (a) 13.4 mol $\text{C}_3\text{H}_8(\text{g})$ (b) $1.47 \times 10^3 \text{ mol C}_3\text{H}_8(\text{l})$ (c) The ratio of moles liquid to moles gas is 110. Many more molecules and moles of liquid fit in a container of fixed volume because there is much less space between molecules in the liquid phase. **10.108** $P_t = 5.3 \times 10^2 \text{ torr}$ **10.111** 42.2 g O_2 **10.115** $T_2 = 687^\circ\text{C}$ **10.120** (a) $P(\text{ideal}) = 177 \text{ atm}$ (b) $P(\text{van der Waals}) = 187.4 \text{ atm}$ (c) Under the conditions of this problem (large number of moles of gas), the correction for the real volume of molecules dominates. **10.123** (a) 44.58% C, 6.596% H, 16.44% Cl, 32.38% N (b) $\text{C}_8\text{H}_{14}\text{N}_5\text{Cl}$ (c) Molar mass of the compound is required in order to determine molecular formula when the empirical formula is known. **10.128** (a) $5.02 \times 10^8 \text{ L CH}_3\text{OH}(\text{l})$ (b) $\text{CH}_4(\text{g}) + 2 \text{O}_2(\text{g}) \longrightarrow \text{CO}_2(\text{g}) + 2 \text{H}_2\text{O}(\text{l})$, $\Delta H^\circ = -890.4 \text{ kJ}$; ΔH for combustion of the methane is $-1.10 \times 10^{13} \text{ kJ}$. $\text{CH}_3\text{OH}(\text{l}) + 3/2 \text{O}_2(\text{g}) \longrightarrow \text{CO}_2(\text{g}) + 2 \text{H}_2\text{O}(\text{l})$, $\Delta H^\circ = -726.6 \text{ kJ}$; ΔH for combustion of the methanol is $-9.00 \times 10^{12} \text{ kJ}$. (c) The enthalpy change upon combustion of 1.00 L of $\text{CH}_4(\text{l})$ is $-2.59 \times 10^4 \text{ kJ}$ and for 1.00 L of $\text{CH}_3\text{OH}(\text{l})$, $-1.79 \times 10^4 \text{ kJ}$. Clearly $\text{CH}_4(\text{l})$ has the higher enthalpy of combustion per unit volume.

CHAPTER 11

11.1 The diagram best describes a liquid. The particles are close together, mostly touching, but there is no regular arrangement or order. This rules out a gaseous sample, where the particles are far apart, and a crystalline solid, which has a regular repeating structure in all three directions. **11.4** (a) In its final state, methane is a gas at 185°C . **11.5** (a) 385 mm Hg (b) 22°C (c) 47°C **11.6** The stronger the inter-

molecular forces, the higher the boiling point of a liquid. Propanol, $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$, has hydrogen bonding and the higher boiling point. **11.7** (a) Normal boiling point, 360 K; normal freezing point, 260 K (b) (i) gas (ii) solid (iii) liquid (c) The triple point is approximately 185 K at 0.45 atm. **11.9** (a) Solid < liquid < gas (b) gas < liquid < solid (c) Matter in the gaseous state is most easily compressed because particles are far apart and there is much empty space. **11.11** $\text{Ar} < \text{CCl}_4 < \text{Si}$ **11.13** (a) The molar volumes of Cl_2 and NH_3 are nearly the same because they are both gases. (b) On cooling to 160 K, both compounds condense from the gas phase to the solid-state, so we expect a significant decrease in the molar volume. (c) The molar volumes are 0.0351 L/mol Cl_2 and 0.0203 L/mol NH_3 (d) Solid-state molar volumes are not as similar as those in the gaseous state, because most of the empty space is gone and molecular characteristics determine properties. $\text{Cl}_2(\text{s})$ is heavier, has a longer bond distance and weaker intermolecular forces, so it has a significantly larger molar volume than $\text{NH}_3(\text{s})$. (e) There is little empty space between molecules in the liquid state, so we expect their molar volumes to be closer to those in the solid state than those in the gaseous state. **11.15** (a) London dispersion forces (b) dipole-dipole and London dispersion forces (c) dipole-dipole forces and in certain cases hydrogen bonding **11.17** (a) SO_2 , dipole-dipole and London dispersion forces (b) CH_3COOH , London dispersion, dipole-dipole, and hydrogen bonding (c) H_2Se , dipole-dipole and London dispersion forces (but not hydrogen bonding) **11.19** (a) *Polarizability* is the ease with which the charge distribution in a molecule can be distorted to produce a transient dipole. (b) Sb is most polarizable because its valence electrons are farthest from the nucleus and least tightly held. (c) in order of increasing polarizability: $\text{CH}_4 < \text{SiH}_4 < \text{SiCl}_4 < \text{GeCl}_4 < \text{GeBr}_4$ (d) The magnitudes of London dispersion forces and thus the boiling points of molecules increase as polarizability increases. The order of increasing boiling points is the order of increasing polarizability given in (c). **11.21** (a) H_2S (b) CO_2 (c) GeH_4 **11.23** Both rodlike butane molecules and spherical 2-methylpropane molecules experience dispersion forces. The larger contact surface between butane molecules facilitates stronger forces and produces a higher boiling point. **11.25** (a) A molecule must contain H atoms, bound to either N, O, or F atoms, in order to participate in hydrogen bonding with like molecules. (b) CH_3NH_2 and CH_3OH **11.27** (a) Replacing a hydroxyl hydrogen with a CH_3 group eliminates hydrogen bonding in that part of the molecule. This reduces the strength of intermolecular forces and leads to a lower boiling point. (b) $\text{CH}_3\text{OCH}_2\text{CH}_2\text{OCH}_3$ is a larger, more polarizable molecule with stronger London dispersion forces and thus a higher boiling point.

11.29

Physical Property	H_2O	H_2S
Normal boiling point, $^\circ\text{C}$	100.00	-60.7
Normal melting point, $^\circ\text{C}$	0.00	-85.5

(a) Based on its much higher normal melting point and boiling point, H_2O has much stronger intermolecular forces. H_2O has hydrogen bonding, while H_2S has dipole-dipole forces. (b) H_2S is probably a typical compound with less empty space in the ordered solid than the liquid, so that the solid is denser than the liquid. For H_2O , maximizing the number of hydrogen bonds to each molecule in the solid requires more empty space than in the liquid, and the solid is less dense. (c) Specific heat is the energy required to raise the temperature of one gram of the substance one degree Celsius. Hydrogen bonding in water is such a strong attractive interaction that the energy required to disrupt it and increase molecular motion is large. **11.31** SO_4^{2-} has a greater negative charge than BF_4^- , so ion-ion electrostatic attractions are greater in sulfate salts and they are less likely to form liquids. **11.33** (a) As temperature increases, the number of molecules with sufficient kinetic energy to overcome intermolecular attractive forces increases, and viscosity and surface tension decrease. (b) The same attractive forces that cause surface molecules to be difficult to separate

(high surface tension) cause molecules elsewhere in the sample to resist movement relative to each other (high viscosity). **11.35** (a) CHBr_3 has a higher molar mass, is more polarizable, and has stronger dispersion forces, so the surface tension is greater. (b) As temperature increases, the viscosity of the oil decreases because the average kinetic energy of the molecules increases. (c) Adhesive forces between polar water and nonpolar car wax are weak, so the large surface tension of water draws the liquid into the shape with the smallest surface area, a sphere. (d) Adhesive forces between nonpolar oil and nonpolar car wax are similar to cohesive forces in oil, so the oil drops spread out on the waxed car hood. **11.37** (a) The three molecules have similar structures and experience the same types of intermolecular forces. As molar mass increases, the strength of dispersion forces increases and the boiling points, surface tension, and viscosities all increase. (b) Ethylene glycol has an $-\text{OH}$ group at both ends of the molecule. This greatly increases the possibilities for hydrogen bonding; the overall intermolecular attractive forces are greater and the viscosity of ethylene glycol is much greater. (c) Water has the highest surface tension but lowest viscosity because it is the smallest molecule in the series. There is no hydrocarbon chain to inhibit their strong attraction to molecules in the interior of the drop, resulting in high surface tension. The absence of an alkyl chain also means the molecules can move around each other easily, resulting in the low viscosity. **11.39** (a) Melting, endothermic (b) evaporation, endothermic (c) deposition, exothermic (d) condensation, exothermic **11.41** Melting does not require separation of molecules, so the energy requirement is smaller than for vaporization, where molecules must be separated. **11.43** $2.3 \times 10^3 \text{ g H}_2\text{O}$ **11.45** (a) 39.3 kJ (b) 60 kJ **11.47** (a) The critical pressure is the pressure required to cause liquefaction at the critical temperature. (b) As the force of attraction between molecules increases, the critical temperature of the compound increases. (c) All the gases in Table 11.5 can be liquefied at the temperature of liquid nitrogen, given sufficient pressure. **11.49** (a) No effect (b) no effect (c) Vapor pressure decreases with increasing intermolecular attractive forces because fewer molecules have sufficient kinetic energy to overcome attractive forces and escape to the vapor phase. (d) Vapor pressure increases with increasing temperature because average kinetic energies of molecules increase. (e) Vapor pressure decreases with increasing density because attractive intermolecular forces increase. **11.51** (a) $\text{CBr}_4 < \text{CHBr}_3 < \text{CH}_2\text{Br}_2 < \text{CH}_2\text{Cl}_2 < \text{CH}_3\text{Cl} < \text{CH}_4$. The trend is dominated by dispersion forces even though four of the molecules are polar. The order of increasing volatility is the order of increasing vapor pressure, decreasing molar mass, and decreasing strength of dispersion forces. (b) Boiling point increases as the strength of intermolecular forces increases; this is the order of decreasing volatility and the reverse of the order in part (a). $\text{CH}_4 < \text{CH}_3\text{Cl} < \text{CH}_2\text{Cl}_2 < \text{CH}_2\text{Br}_2 < \text{CHBr}_3 < \text{CBr}_4$ **11.53** (a) The temperature of the water in the two pans is the same. (b) Vapor pressure does not depend on either volume or surface area of the liquid. At the same temperature, the vapor pressures of water in the two containers are the same. **11.55** (a) Approximately 48°C (b) approximately 340 torr (c) approximately 17°C (d) approximately 1000 torr **11.57** (a) The critical point is the temperature and pressure beyond which the gas and liquid phases are indistinguishable. (b) The line that separates the gas and liquid phases ends at the critical point because at conditions beyond the critical temperature and pressure, there is no distinction between gas and liquid. In experimental terms a gas cannot be liquefied at temperatures higher than the critical temperature, regardless of pressure. **11.59** (a) $\text{H}_2\text{O}(\text{g})$ will condense to $\text{H}_2\text{O}(\text{s})$ at approximately 4 torr; at a higher pressure, perhaps 5 atm or so, $\text{H}_2\text{O}(\text{s})$ will melt to form $\text{H}_2\text{O}(\text{l})$. (b) At 100°C and 0.50 atm, water is in the vapor phase. As it cools, water vapor condenses to the liquid at approximately 82°C , the temperature where the vapor pressure of liquid water is 0.50 atm. Further cooling results in freezing at approximately 0°C . The freezing point of water increases with decreasing pressure, so at 0.50 atm the freezing temperature is very slightly above 0°C . **11.61** (a) 24 K (b) Neon sublimates at pressures less than the triple point pressure, 0.43 atm. (c) No **11.63** (a) Methane on the surface of Titan is likely to exist in both solid and liquid forms. (b) As

pressure decreases upon moving away from the surface of Titan, $\text{CH}_4(\text{l})$ (at -178°C) will vaporize to $\text{CH}_4(\text{g})$, and $\text{CH}_4(\text{s})$ (at temperatures below -180°C) will sublime to $\text{CH}_4(\text{g})$. **11.65** In a nematic liquid crystalline phase, molecules are aligned along their long axes, but the molecular ends are not aligned. Molecules are free to translate in all dimensions, but they cannot tumble or rotate out of the molecular plane, or the order of the nematic phase is lost and the sample becomes an ordinary liquid. In an ordinary liquid, molecules are randomly oriented and free to move in any direction. **11.67** The presence of polar groups or nonbonded electron pairs leads to relatively strong dipole-dipole interactions between molecules. These are a significant part of the orienting forces necessary for liquid crystal formation. **11.69** Because order is maintained in at least one dimension, the molecules in a liquid-crystalline phase are not totally free to change orientation. This makes the liquid-crystalline phase more resistant to flow, more viscous, than the isotropic liquid. **11.71** Melting provides kinetic energy sufficient to disrupt molecular alignment in one dimension in the solid, producing a smectic phase with ordering in two dimensions. Additional heating of the smectic phase provides kinetic energy sufficient to disrupt alignment in another dimension, producing a nematic phase with one-dimensional order. **11.73** (a) Decrease (b) increase (c) increase (d) increase (e) increase (f) increase (g) increase **11.77** When a halogen is substituted for H in benzene, molar mass, polarizability and strength of dispersion forces increase; the order of increasing molar mass is the order of increasing boiling points for the first three compounds. $\text{C}_6\text{H}_5\text{OH}$ experiences hydrogen bonding, the strongest force between neutral molecules, so it has the highest boiling point. **11.82** (a) Evaporation is an endothermic process. The heat required to vaporize sweat is absorbed from your body, helping to keep it cool. (b) The vacuum pump reduces the pressure of the atmosphere above the water until atmospheric pressure equals the vapor pressure of water and the water boils. Boiling is an endothermic process, and the temperature drops if the system is not able to absorb heat from the surroundings fast enough. As the temperature of the water decreases, the water freezes. **11.86** At low Antarctic temperatures, molecules in the liquid crystalline phase have less kinetic energy due to temperature, and the applied voltage may not be sufficient to overcome orienting forces among the ends of molecules. If some or all of the molecules do not rotate when the voltage is applied, the display will not function properly. **11.90**

(a) Molar mass: Compounds (i) and (ii) have similar rodlike structures. The longer chain in (ii) leads to greater molar mass, stronger London dispersion forces, and higher heat of vaporization. (b) Molecular shape: Compounds (iii) and (v) have the same chemical formula and molar mass but different molecular shapes. The more rodlike shape of (v) leads to more contact between molecules, stronger dispersion forces, and higher heat of vaporization. (c) Molecular polarity: Compound (iv) has a smaller molar mass than (ii) but a larger heat of vaporization, which must be due to the presence of dipole-dipole forces. (d) Hydrogen bonding interactions: Molecules (v) and (vi) have similar structures. Even though (v) has larger molar mass and dispersion forces, hydrogen bonding causes (vi) to have the higher heat of vaporization. **11.93** $P(\text{benzene vapor}) = 98.7 \text{ torr}$

CHAPTER 12

12.1

Two-dimensional structure

	(i)	(ii)
(a) unit cell		
(b) lattice	square	square
(c) cell contents	one black, one white	one black

12.3 (a) 1 Re and 3 O atoms per unit cell (b) 3.92 Å (c) 6.46 g/cm³

12.5 We expect linear polymer (a), with ordered regions, to be denser and have a higher melting point than branched polymer (b). 12.7 In molecular solids, relatively weak intermolecular forces bind the molecules in the lattice, so relatively little energy is required to disrupt these forces. In covalent-network solids, covalent bonds join atoms into an extended network. Melting or deforming a covalent-network solid means breaking covalent bonds, which requires a large amount of energy. 12.9 (a) Hydrogen bonding, dipole-dipole forces, London dispersion forces (b) covalent chemical bonds (c) ionic bonds (d) metallic bonds 12.11 (a) Ionic (b) metallic (c) covalent-network (It could also be characterized as ionic with some covalent character to the bonds.) (d) molecular (e) molecular (f) molecular 12.13 Because of its relatively high melting point and properties as a conducting solution, the solid must be ionic.

12.15

12.17

Two-dimensional structure

	(i)	(ii)
(a) unit cell		
(b) γ, a, b	$\lambda = 90^\circ, a = b$	$\lambda = 120^\circ, a = b$
(c) lattice type	square	hexagonal

12.19 (a) Orthorhombic (d) tetragonal 12.21 Triclinic, rhombohedral 12.23 There is a minimum of two (metal) atoms in a body-centered cubic unit cell. 12.25 (a) Primitive hexagonal unit cell (b) NiAs 12.27 Moving left to right in the period, atomic mass and Z_{eff} increase. The increase in Z_{eff} leads to smaller bonding atomic radii and atomic volume. Mass increases, volume decreases, and density increases in the series. The variation in densities reflects shorter metal-metal bond distances and an increase in the extent of metal-metal bonding. The strength of metal-metal bonds in the series

is probably the most important factor influencing the increase in density. 12.29 (a) Structure types A and C have equally dense packing and are more densely packed than structure type B. (b) Structure type B is least densely packed. 12.31 (a) The radius of an Ir atom is 1.355 Å. (b) The density of Ir is 22.67 g/cm³ 12.33 (a) 4 Al atoms per unit cell (b) coordination number = 12 (c) $a = 4.04 \text{ \AA}$ or $4.04 \times 10^{-8} \text{ cm}$ (d) density = 2.71 g/cm³ 12.35 An alloy contains atoms of more than one element and has the properties of a metal. In a solution alloy the components are randomly dispersed. In a heterogeneous alloy the components are not evenly dispersed and can be distinguished at a macroscopic level. In an intermetallic compound the components have interacted to form a compound substance, as in Cu₃As. 12.37 (a) Interstitial alloy (b) substitutional alloy (c) intermetallic compound 12.39 (a) True (b) false (c) false 12.41 (a) Nickel or palladium, substitutional alloy (b) copper, substitutional alloy (c) indium, intermetallic compound (d) silver, substitutional alloy 12.43 In the electron-sea model, valence electrons move about the metallic lattice, while metal atoms remain more or less fixed in position. Under the influence of an applied potential, the electrons are free to move throughout the structure, giving rise to thermal and electrical conductivity.

12.45

(a) Six AOs require six MOs (b) zero nodes in the lowest energy orbital (c) five nodes in highest energy orbital (d) two nodes in the HOMO (e) three nodes in the LUMO. 12.47 (a) Ag (b) Zn. Ductility decreases as the strength of metal-metal bonding increases, producing a stiffer lattice, less susceptible to distortion. 12.49 Moving from Y to Mo, the number of valence electrons, occupancy of the bonding band, and strength of metallic bonding increase. Stronger metallic bonding requires more energy to break bonds and mobilize atoms, resulting in higher melting points. 12.51 (a) SrTiO₃ (b) Each Sr atom is coordinated to twelve O atoms in eight unit cells that contain the Sr atom. 12.53 (a) $a = 4.70 \text{ \AA}$ (b) 2.69 g/cm³ 12.55 (a) 7.711 g/cm³ (b) We expect Se²⁻ to have a larger ionic radius than S²⁻, so HgSe will occupy a larger volume and the unit cell edge will be longer. (c) The density of HgSe is 8.241 g/cm³. The greater mass of Se accounts for the greater density of HgSe. 12.57 (a) Cs⁺ and I⁻ have the most similar radii and will adopt the CsCl-type structure. The radii of Na⁺ and I⁻ are somewhat different; NaI will adopt the NaCl-type structure. The radii of Cu⁺ and I⁻ are very different; CuI has the ZnS-type structure. (b) CsI, 8; NaI, 6; CuI, 4 12.59 (a) 6 (b) 3 (c) 6 12.61 (a) False (b) true 12.63 (a) Ionic solids are much more likely to dissolve in water. (b) Covalent-network solids can become electrical conductors via chemical substitution. 12.65 (a) CdS (b) GaN (c) GaAs 12.67 Ge or Si (Ge is closer to Ga in bonding atomic radius.) 12.69 (a) A 1.1 eV photon corresponds to a wavelength of $1.1 \times 10^{-6} \text{ m}$. (b) According to the figure, Si can absorb a portion of the visible light that comes from the sun. 12.71 $\lambda = 560 \text{ nm}$ 12.73 The band gap is approximately 1.85 eV, which corresponds to a wavelength of 672 nm. 12.75 Monomers are small molecules with low molecular mass that are joined together to form polymers. Three monomers mentioned in this chapter are

Propylene
(propene)Styrene
(phenyl ethene)Isoprene
(2-methyl-1,3-butadiene)

12.77

If a dicarboxylic acid and a dialcohol are combined, there is the potential for propagation of the polymer chain at both ends of both monomers.

12.81

12.83 Flexibility of molecular chains causes flexibility of the bulk polymer. Flexibility is enhanced by molecular features that inhibit order, such as branching, and diminished by features that encourage order, such as cross-linking or delocalized π electron density. Cross-linking, the formation of chemical bonds between polymer chains, reduces flexibility of the molecular chains, increases the hardness of the material, and decreases the chemical reactivity of the polymer. 12.85 No. The function of the polymer determines whether high molecular mass and high degree of crystallinity are desirable properties. If the polymer will be used as a flexible wrapping or fiber, rigidity that is due to high molecular mass is an undesirable property. 12.87 If a solid has nanoscale dimensions of 1–10 nm, there may not be enough atoms contributing atomic orbitals to produce continuous energy bands of molecular orbitals. 12.89 (a) False. As particle size decreases, the band gap increases. (b) False. As particle size decreases, wavelength decreases. 12.91 2.47×10^5 Au atoms 12.94 The face-centered structure will have the greater density. 12.98 (a) CsCl, primitive cubic lattice (b) Au, face-centered cubic lattice (c) NaCl, face-centered cubic lattice (d) Po, primitive cubic lattice, rare for metals (e) ZnS, face-centered cubic lattice 12.99 White tin has a structure characteristic of a metal, while gray tin has the diamond structure characteristic of group 4A semiconductors. Metallic white tin has the

longer bond distance because the valence electrons are shared with twelve nearest neighbors rather than being localized in four bonds as in gray tin.

12.103

Teflon™ is formed by addition polymerization. 12.105 Diffraction, the phenomenon that enables us to measure interatomic distances in crystals, is most efficient when the wavelength of light is similar to or smaller than the size of the object doing the diffracting. Atom sizes are on the order of 1–10 Å, and the wavelengths of X-rays are also in this range. Visible light, 400–700 nm or 4000–7000 Å, is too long to be diffracted effectively by atoms (electrons) in crystals. 12.107 In a diffraction experiment, we expect a Ge crystal to diffract X-rays at a smaller θ angle than a Si crystal, assuming the X-rays have the same wavelength. 12.109 (a) The bonds in a semiconductor will be weakened by n -type doping. (b) The bonds in a semiconductor will also be weakened by p -type doping. 12.112 (a) 109° (b) 120° 12.113 (a) $\Delta H = -82$ kJ/mol (b) $\Delta H = -14$ kJ/mol (of either reactant) (c) $\Delta H = 0$ kJ

CHAPTER 13

13.1 (a) $<$ (b) $<$ (c) 13.3 The greater the lattice energy of an ionic solid, the more endothermic the dissolving process and the less soluble the salt in water. 13.7 Vitamin B₆ is largely water soluble because of its small size and capacity for extensive hydrogen-bonding interactions. Vitamin E is largely fat soluble. The long, rodlike hydrocarbon chain will lead to strong dispersion forces among vitamin E and mostly nonpolar fats. 13.9 (a) Yes, the molarity changes with a change in temperature. Molarity is defined as moles solute per unit volume of solution. A change of temperature changes solution volume and molarity. (b) No, molarity does not change with change in temperature. Molality is defined as moles solute per kilogram of solvent. Temperature affects neither mass nor moles. 13.13 If the magnitude of ΔH_{mix} is small relative to the magnitude of ΔH_{solute} , ΔH_{soln} will be large and endothermic (energetically unfavorable) and not much solute will dissolve. 13.15 (a) Dispersion (b) hydrogen bonding (c) ion–dipole (d) dipole–dipole 13.17 Very soluble. In order for ΔH_{soln} to be negative, ΔH_{mix} must have a greater magnitude than $(\Delta H_{\text{solute}} + \Delta H_{\text{solvent}})$. The entropy of mixing always encourages solubility. In this case, the enthalpy of the system decreases and the entropy increases, so the ionic compound dissolves. 13.19 (a) ΔH_{solute} (b) ΔH_{mix} 13.21 (a) Since the solute and solvent experience very similar London dispersion forces, the energy required to separate them individually and the energy released when they are mixed are approximately equal. $\Delta H_{\text{solute}} + \Delta H_{\text{solvent}} \approx -\Delta H_{\text{mix}}$. Thus, ΔH_{soln} is nearly zero. (b) Since no strong intermolecular forces prevent the molecules from mixing, they do so spontaneously because of the increase in randomness. 13.23 (a) Supersaturated (b) Add a seed crystal. A seed crystal provides a nucleus of prealigned molecules, so that ordering of the dissolved particles (crystallization) is more facile. 13.25 (a) Unsaturated (b) saturated (c) saturated (d) unsaturated 13.27 The liquids water and glycerol form homogenous mixtures (solutions) regardless of the relative amounts of the two components. The —OH groups of glycerol facilitate strong hydrogen bonding similar to that in water; like dissolves like. 13.29 Toluene, C₆H₅CH₃, is the best solvent for nonpolar solutes. Without polar groups or nonbonding electron pairs, it forms only dispersion interactions with itself and other molecules. 13.31 (a) Dispersion interactions among nonpolar CH₃(CH₂)₁₆— chains dominate the properties of stearic acid, causing

it to be more soluble in nonpolar CCl_4 . (b) Dioxane can act as a hydrogen bond acceptor, so it will be more soluble than cyclohexane in water. **13.33** (a) CCl_4 is more soluble because dispersion forces among nonpolar CCl_4 molecules are similar to dispersion forces in hexane. (b) C_6H_6 is a nonpolar hydrocarbon and will be more soluble in the similarly nonpolar hexane. (c) The long, rodlike hydrocarbon chain of octanoic acid forms strong dispersion interactions and causes it to be more soluble in hexane. **13.35** (a) A sealed container is required to maintain a partial pressure of $\text{CO}_2(\text{g})$ greater than 1 atm above the beverage. (b) Since the solubility of gases increases with decreasing temperature, more $\text{CO}_2(\text{g})$ will remain dissolved in the beverage if it is kept cool. **13.37** $S_{\text{He}} = 5.6 \times 10^{-4} \text{ M}$, $S_{\text{N}_2} = 9.0 \times 10^{-4} \text{ M}$ **13.39** (a) 2.15% Na_2SO_4 by mass (b) 3.15 ppm Ag **13.41** (a) $X_{\text{CH}_3\text{OH}} = 0.0427$ (b) 7.35% CH_3OH by mass (c) 2.48 *m* CH_3OH **13.43** (a) $1.46 \times 10^{-2} \text{ M Mg}(\text{NO}_3)_2$ (b) 1.12 *M* $\text{LiClO}_4 \cdot 3 \text{ H}_2\text{O}$ (c) 0.350 *M* HNO_3 **13.45** (a) 4.70 *m* C_6H_6 (b) 0.235 *m* NaCl **13.47** (a) 43.01% H_2SO_4 by mass (b) $X_{\text{H}_2\text{SO}_4} = 0.122$ (c) 7.69 *m* H_2SO_4 (d) 5.827 *M* H_2SO_4 **13.49** (a) $X_{\text{CH}_3\text{OH}} = 0.227$ (b) 7.16 *m* CH_3OH (c) 4.58 *M* CH_3OH **13.51** (a) 0.150 mol SrBr_2 (b) 1.56×10^{-2} mol KCl (c) 4.44×10^{-2} mol $\text{C}_6\text{H}_{12}\text{O}_6$ **13.53** (a) Weigh out 1.3 g KBr , dissolve in water, dilute with stirring to 0.75 L. (b) Weigh out 2.62 g KBr , dissolve it in 122.38 g H_2O to make exactly 125 g of 0.180 *m* solution. (c) Dissolve 244 g KBr in water, dilute with stirring to 1.85 L. (d) Weigh 10.1 g KBr , dissolve it in a small amount of water, and dilute to 0.568 L. **13.55** 71% HNO_3 by mass **13.57** (a) 3.82 *m* Zn (b) 26.8 *M* Zn **13.59** $1.8 \times 10^{-3} \text{ MCO}_2$ **13.61** Freezing point depression, $\Delta T_f = K_f(m)$; boiling-point elevation, $\Delta T_b = K_b(m)$; osmotic pressure, $\Pi = MRT$; vapor pressure lowering, $P_A = X_A P_A^\circ$ **13.63** (a) Sucrose has a greater molar mass than glucose, so the sucrose solution will contain fewer particles and have a higher vapor pressure. **13.65** (a) $P_{\text{H}_2\text{O}} = 186.4$ torr (b) 78.9 g $\text{C}_3\text{H}_8\text{O}_2$ **13.67** (a) $X_{\text{Eth}} = 0.2812$ (b) $P_{\text{soln}} = 238$ torr (c) X_{Eth} in vapor = 0.472 **13.69** (a) Because NaCl is a strong electrolyte, one mole of NaCl produces twice as many dissolved particles as one mole of the molecular solute $\text{C}_6\text{H}_{12}\text{O}_6$. Boiling-point elevation is directly related to total moles of dissolved particles, so 0.10 *m* NaCl has the higher boiling point. (b) 0.10 *m* NaCl : $\Delta T_b = 0.101^\circ\text{C}$, $T_b = 100.1^\circ\text{C}$; 0.10 *m* $\text{C}_6\text{H}_{12}\text{O}_6$: $\Delta T_b = 0.051^\circ\text{C}$, $T_b = 100.1^\circ\text{C}$ (c) Interactions between ions in solution result in nonideal behavior. **13.71** 0.050 *m* LiBr < 0.120 *m* glucose < 0.050 *m* $\text{Zn}(\text{NO}_3)_2$ **13.73** (a) $T_f = -115.0^\circ\text{C}$, $T_b = 78.7^\circ\text{C}$ (b) $T_f = -67.3^\circ\text{C}$, $T_b = 64.2^\circ\text{C}$ (c) $T_f = -0.4^\circ\text{C}$, $T_b = 100.1^\circ\text{C}$ (c) $T_f = -0.6^\circ\text{C}$, $T_b = 100.2^\circ\text{C}$ **13.75** 167 g $\text{C}_2\text{H}_6\text{O}_2$ **13.77** $\Pi = 0.0168 \text{ atm} = 12.7 \text{ torr}$ **13.79** Experimental molar mass of adrenaline is $1.8 \times 10^2 \text{ g}$. The structure shows a molecular formula of $\text{C}_9\text{H}_{13}\text{NO}_3$, with a molar mass of 183 g. The two values agree to two significant figures, the precision of the experiment. **13.81** Molar mass of lysozyme = $1.39 \times 10^4 \text{ g}$ **13.83** (a) $i = 2.8$ (b) The more concentrated the solution, the greater the ion pairing and the smaller the measured value of i . **13.85** (a) In the gaseous state, particles are far apart and intermolecular attractive forces are small. When two gases combine, all terms in Equation 13.1 are essentially zero and the mixture is always homogeneous. (b) To determine whether Faraday's dispersion is a true solution or a colloid, shine a beam of light on it. If light is scattered, the dispersion is a colloid. **13.87** (a) Hydrophobic (b) hydrophilic (c) hydrophobic (d) hydrophobic (but stabilized by adsorbed charges). **13.89** When electrolytes are added to a suspension of proteins, dissolved ions form ion pairs with the protein surface charges, effectively neutralizing them. The protein's capacity for ion-dipole interactions with water is diminished and the colloid separates into a protein layer and a water layer. **13.91** The periphery of the BHT molecule is mostly hydrocarbon-like groups, such as $-\text{CH}_3$. The one $-\text{OH}$ group is rather buried inside and probably does little to enhance solubility in water. Thus, BHT is more likely to be soluble in the nonpolar hydrocarbon hexane, C_6H_{14} , than in polar water. **13.94** (a) $k_{\text{Rn}} = 7.27 \times 10^{-3} \text{ mol/L-atm}$ (b) $P_{\text{Rn}} = 1.1 \times 10^{-4} \text{ atm}$; $S_{\text{Rn}} = 8.1 \times 10^{-7} \text{ M}$ **13.98** (a) 2.69 *m* LiBr (b) $X_{\text{LiBr}} = 0.0994$ (c) 81.1% LiBr by mass **13.100** $X_{\text{H}_2\text{O}} = 0.808$; 0.0273 mol ions; 0.0136 mol NaCl **13.103** (a) -0.6°C (b) -0.4°C **13.106** (a) CF_4 , $1.7 \times 10^{-4} \text{ m}$; CClF_3 , $9 \times 10^{-4} \text{ m}$; CCl_2F_2 , $2.3 \times 10^{-2} \text{ m}$; CHClF_2 ,

$3.5 \times 10^{-2} \text{ m}$ (b) Molality and molarity are numerically similar when kilograms solvent and liters solution are nearly equal. This is true when solutions are dilute and when the density of the solvent is nearly 1 g/mL, as in this exercise. (c) Water is a polar solvent; the solubility of solutes increases as their polarity increases. Nonpolar CF_4 has the lowest solubility and the most polar fluorocarbon, CHClF_2 , has the greatest solubility in H_2O . (d) The Henry's law constant for CHClF_2 is $3.5 \times 10^{-2} \text{ mol/L-atm}$. This value is greater than the Henry's law constant for $\text{N}_2(\text{g})$ because $\text{N}_2(\text{g})$ is nonpolar and of lower molecular mass than CHClF_2 .

13.109

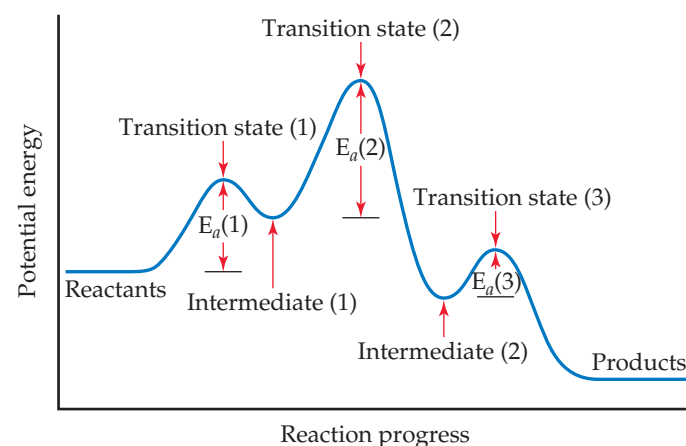

(a) cation (g) + anion (g) + solvent

(b) Lattice energy (U) is inversely related to the distance between ions, so salts with large cations like $(\text{CH}_3)_4\text{N}^+$ have smaller lattice energies than salts with simple cations like Na^+ . Also the $-\text{CH}_3$ groups in the large cation are capable of dispersion interactions with nonpolar groups of the solvent molecules, resulting in a more negative solvation energy of the gaseous ions. Overall, for salts with larger cations, lattice energy is smaller (less positive), the solvation energy of the gaseous ions is more negative, and ΔH_{soln} is less endothermic. These salts are more soluble in polar nonaqueous solvents. **13.112** The freezing point of the $\text{LiOH}(\text{aq})$ solution is essentially zero, $T_f = -0.00058^\circ\text{C}$.

CHAPTER 14

14.1 Vessel 2 **14.3** Equation (d) **14.9** (1) Total potential energy of the reactants (2) E_a , activation energy of the reaction (3) ΔE , net energy change for the reaction (4) total potential energy of the products **14.12** (a) $\text{NO}_2 + \text{F}_2 \longrightarrow \text{NO}_2\text{F} + \text{F}$; $\text{NO}_2 + \text{F} \longrightarrow \text{NO}_2\text{F}$ (b) $2\text{NO}_2 + \text{F}_2 \longrightarrow 2\text{NO}_2\text{F}$ (c) F (atomic fluorine) is the intermediate (d) rate = $k[\text{NO}_2][\text{F}_2]$

14.16

14.17 (a) Reaction rate is the change in the amount of products or reactants in a given amount of time. (b) Rates depend on concentration of reactants, surface area of reactants, temperature, and presence of catalyst. (c) The stoichiometry of the reaction (mole ratios of reactants and products) must be known to relate rate of disappearance of reactants to rate of appearance of products.

14.19

Time (min)	Mol A	(a) Mol B	[A] (mol/L)	$\Delta[A]$ (mol/L)	(b) Rate (M/s)
0	0.065	0.000	0.65		
10	0.051	0.014	0.51	-0.14	2.3×10^{-4}
20	0.042	0.023	0.42	-0.09	1.5×10^{-4}
30	0.036	0.029	0.36	-0.06	1.0×10^{-4}
40	0.031	0.034	0.31	-0.05	0.8×10^{-4}

(c) $\Delta[B]_{\text{avg}}/\Delta t = 1.3 \times 10^{-4} \text{ M/s}$

14.21 (a)

Time (s)	Time Interval (s)	Concentration (M)	ΔM	Rate (M/s)
0		0.0165		
2,000	2,000	0.0110	-0.0055	28×10^{-7}
5,000	3,000	0.00591	-0.0051	17×10^{-7}
8,000	3,000	0.00314	-0.00277	9.23×10^{-7}
12,000	4,000	0.00137	-0.00177	4.43×10^{-7}
15,000	3,000	0.00074	-0.00063	2.1×10^{-7}

(b) The average rate of reaction is $1.05 \times 10^{-6} \text{ M/s}$. (c) From the slopes of the tangents to the graph, the rates are $12 \times 10^{-7} \text{ M/s}$ at 5000 s, $5.8 \times 10^{-7} \text{ M/s}$ at 8000 s.

14.23

(a) $-\Delta[\text{H}_2\text{O}_2]/\Delta t = \Delta[\text{H}_2]/\Delta t = \Delta[\text{O}_2]/\Delta t$ (b) $-\frac{1}{2}\Delta[\text{N}_2\text{O}]/\Delta t = \frac{1}{2}\Delta[\text{N}_2]/\Delta t = \Delta[\text{O}_2]/\Delta t$ (c) $-\Delta[\text{N}_2]/\Delta t = -1/3\Delta[\text{H}_2]/\Delta t = -1/2\Delta[\text{NH}_3]/2\Delta t$ (d) $-\Delta[\text{C}_2\text{H}_5\text{NH}_2]/\Delta t = \Delta[\text{C}_2\text{H}_4]/\Delta t = \Delta[\text{NH}_3]/\Delta t$ 14.25 (a) $-\Delta[\text{O}_2]/\Delta t = 0.24 \text{ mol/s}$; $\Delta[\text{H}_2\text{O}]/\Delta t = 0.48 \text{ mol/s}$ (b) P_{total} decreases by 28 torr/min. 14.27 (a) If $[\text{A}]$ doubles, there is no change in the rate or the rate constant. The overall rate is unchanged because $[\text{A}]$ does not appear in the rate law; the rate constant changes only with a change in temperature. (b) The reaction is zero order in A, second order in B, and second order overall. (c) units of $k = \text{M}^{-1}\text{s}^{-1}$ 14.29 (a) Rate = $k[\text{N}_2\text{O}_5]$ (b) Rate = $1.16 \times 10^{-4} \text{ M/s}$ (c) When the concentration of N_2O_5 doubles, the rate doubles. (d) When the concentration of N_2O_5 is halved, the rate doubles.14.31 (a, b) $k = 1.7 \times 10^2 \text{ M}^{-1}\text{s}^{-1}$ (c) If $[\text{OH}^-]$ is tripled, the rate triples. (d) If $[\text{OH}^-]$ and $[\text{CH}_3\text{Br}]$ both triple, the rate increases by a factor of 9. 14.33 (a) Rate = $k[\text{OCl}^-][\text{I}^-]$ (b) $k = 60 \text{ M}^{-1}\text{s}^{-1}$ (c) Rate = $6.0 \times 10^{-5} \text{ M/s}$ 14.35 (a) Rate = $k[\text{BF}_3][\text{NH}_3]$ (b) The reaction is second order overall. (c) $k_{\text{avg}} = 3.41 \text{ M}^{-1}\text{s}^{-1}$ (d) 0.170 M/s 14.37 (a) Rate = $k[\text{NO}]^2[\text{Br}_2]$ (b) $k_{\text{avg}} = 1.2 \times 10^4 \text{ M}^{-2}\text{s}^{-1}$ (c) $\frac{1}{2}\Delta[\text{NOBr}]/\Delta t = -\Delta[\text{Br}_2]/\Delta t$ (d) $-\Delta[\text{Br}_2]/\Delta t = 8.4 \text{ M/s}$ 14.39 (a) $[\text{A}]_0$ is the molar concentration of reactant A at time zero. $[\text{A}]_t$ is the molar concentration of reactant A at time t . $t_{1/2}$ is the time required to reduce $[\text{A}]_0$ by a factor of 2. k is the rate constant for a particular reaction. (b) A graph of $\ln[\text{A}]$ versus time yields a straight line for a first-order reaction. (c) On a graph of $\ln[\text{A}]$ versus time, the rate constant is the (-slope) of the straight line. 14.41 Plot $[\text{A}]$ versus time. 14.43 (a) $k = 3.0 \times 10^{-6} \text{ s}^{-1}$ (b) $t_{1/2} = 3.2 \times 10^4 \text{ s}$ 14.45 (a) $P = 30 \text{ torr}$ (b) $t = 51 \text{ s}$ 14.47 Plot $(\ln P_{\text{SO}_2\text{Cl}_2})$ versus time, $k = -\text{slope} = 2.19 \times 10^{-5} \text{ s}^{-1}$ 14.49 (a) The plot of $1/[\text{A}]$ versus time is linear, so the reaction is second order in $[\text{A}]$.(b) $k = 0.040 \text{ M}^{-1}\text{min}^{-1}$ (c) $t_{1/2} = 38 \text{ min}$ 14.51 (a) The plot of $1/[\text{NO}_2]$ versus time is linear, so the reaction is second order in NO_2 .(b) $k = \text{slope} = 10 \text{ M}^{-1}\text{s}^{-1}$ (c) rate at $0.200 \text{ M} = 0.400 \text{ M/s}$; rate at $0.100 \text{ M} = 0.100 \text{ M/s}$; rate at $0.050 \text{ M} = 0.025 \text{ M/s}$ 14.53 (a) The energy of the collision and the orientation of the molecules when they collide determine whether a reaction will occur. (b) At a higher temperature, there are more total collisions and each collision is moreenergetic. (c) The rate constant usually increases with an increase in reaction temperature. 14.55 $f = 4.94 \times 10^{-2}$. At 400 K approximately 1 out of 20 molecules has this kinetic energy.

14.57 (a)

(b) E_a (reverse) = 73 kJ 14.59 (a) False. If you compare two reactions with similar collision factors, the one with the larger activation energy will be slower. (b) False. A reaction that has a small rate constant will have either a small frequency factor, a large activation energy, or both. (c) True. 14.61 Reaction (b) is fastest and reaction (c) is slowest. 14.63 (a) $k = 1.1 \text{ s}^{-1}$ (b) $k = 13 \text{ s}^{-1}$ (c) The method in parts (a) and (b) assumes that the collision model and thus the Arrhenius equation describe the kinetics of the reactions. That is, activation energy is constant over the temperature range under consideration.14.65 A plot of $\ln k$ versus $1/T$ has a slope of -5.71×10^3 ; $E_a = -R(\text{slope}) = 47.5 \text{ kJ/mol}$. 14.67 The reaction will occur 88 times faster at 50°C , assuming equal initial concentrations.14.69 (a) An elementary reaction is a process that occurs in a single event; the order is given by the coefficients in the balanced equation for the reaction. (b) A unimolecular elementary reaction involves only one reactant molecule; a bimolecular elementary reaction involves two reactant molecules. (c) A reaction mechanism is a series of elementary reactions that describes how an overall reaction occurs and explains the experimentally determined rate law. 14.71 A transition state is a high-energy complex formed when one or more reactants collide and distort in a way that can lead to formation of product(s). An intermediate is the product of an early elementary reaction in a multistep reaction mechanism. 14.73 (a) Unimolecular, rate = $k[\text{Cl}_2]$ (b) bimolecular, rate = $k[\text{OCl}^-][\text{H}_2\text{O}]$ (c) bimolecular, rate = $k[\text{NO}][\text{Cl}_2]$ 14.75 (a) Two intermediates, B and C. (b) three transition states (c) $\text{C} \rightarrow \text{D}$ is fastest. (d) endothermic 14.77 (a) $\text{H}_2(\text{g}) + 2\text{ICl}(\text{g}) \rightarrow \text{I}_2(\text{g}) + 2\text{HCl}(\text{g})$ (b) HI is the intermediate. (c) If the first step is slow, the observed rate law is rate = $k[\text{H}_2][\text{ICl}]$. 14.79 The graph of $1/[\text{NO}]$ versus time is linear with positive slope, indicating that the reaction is second order in $[\text{NO}]$. The rate law obtained by assuming the second step is rate determining is rate = $[\text{NO}]^2[\text{Cl}_2]$. The two-step mechanism is consistent with the data. 14.81 (a) A catalyst is a substance that changes (usually increases) the speed of a chemical reaction without undergoing a permanent chemical change itself. (b) A homogeneous catalyst is in the same phase as the reactants, while a heterogeneous catalyst is in a different phase. (c) A catalyst has no effect on the overall enthalpy change for a reaction, but it does affect activation energy. It can also affect the frequency factor. 14.83 (a) 270 Pt atoms in a 2.0-nm sphere (b) 200 Pt atoms on the surface of a 2.0-nm sphere (c) 74% Pt atoms on the surface (d) 4300 Pt atoms in a 5.0-nm sphere; 1300 Pt atoms on the surface; 30% Pt atoms on the surface (e) The 2-nm sphere will definitely be more catalytically active because it has a much greater percentage of its atoms on the surface where they can participate in the chemical reaction. 14.85 (a) Multiply the coefficients in the first reaction by 2 and sum. (b) $\text{NO}_2(\text{g})$ is a catalyst because it is consumed and then reproduced in the reaction sequence. (c) This is a homogeneous catalysis. 14.87 (a) Use of chemically stable supports makes it possible to obtain very large surface areas per unit mass of the precious metal catalyst because the metal can be deposited in a very thin, even monomolecular, layer on the surface of the support. (b) The greater the surface area of the catalyst, the more reaction sites, the greater the rate of the catalyzed reaction. 14.89 To put

two D atoms on a single carbon, it is necessary that one of the already existing C—H bonds in ethylene be broken while the molecule is adsorbed, so that the H atom moves off as an adsorbed atom and is replaced by a D atom. This requires a larger activation energy than simply adsorbing C₂H₄ and adding one D atom to each carbon.

14.91 (a) Living organisms operate efficiently in a very narrow temperature range; the role of enzymes as homogeneous catalysts that speed up desirable reactions, without heating and undesirable side effects, is crucial for biological systems. (b) catalase: $2\text{H}_2\text{O}_2 \longrightarrow 2\text{H}_2\text{O} + \text{O}_2$; nitrogenase: $\text{N}_2 \longrightarrow 2\text{NH}_3$ (nitrogen fixation) (c) This model assumes that the rate of the bound substrate being chemically transformed into bound product is slow and rate determining. **14.93** Carbonic anhydrase lowers the activation energy of the reaction by 42 kJ. **14.95** (a) The catalyzed reaction is approximately 10,000,000 times faster at 25 °C. (b) The catalyzed reaction is 180,000 times faster at 125 °C. **14.99** (a) Rate = $4.7 \times 10^{-5} \text{ M/s}$ (b, c) $k = 0.84 \text{ M}^{-2}\text{s}^{-1}$ (d) If the [NO] is increased by a factor of 1.8, the rate would increase by a factor of 3.2. **14.101** The reaction is second order in NO₂. If $[\text{NO}_2]_0 = 0.100 \text{ M}$ and $[\text{NO}_2]_t = 0.025 \text{ M}$, use the integrated form of the second-order rate equation to solve for t . $t = 48 \text{ s}$ **14.105** (a) The half-life of ²⁴¹Am is $4.3 \times 10^2 \text{ yr}$, that of ¹²⁵I is 63 days (b) ¹²⁵I decays at a much faster rate. (c) 0.13 mg of each isotope remains after 3 half-lives. (d) The amount of ²⁴¹Am remaining after 4 days is 1.00 mg. The amount of ¹²⁵I remaining after 4 days is 0.957 grams. **14.109** The plot of $1/[\text{C}_5\text{H}_6]$ versus time is linear and the reaction is second order. $k = 0.167 \text{ M}^{-1}\text{s}^{-1}$ **14.112** (a) When the two elementary reactions are added, N₂O₂(g) appears on both sides and cancels, resulting in the overall reaction. $2\text{NO}(\text{g}) + \text{H}_2(\text{g}) \longrightarrow \text{N}_2\text{O}(\text{g}) + \text{H}_2\text{O}(\text{g})$ (b) First reaction, $-\frac{[\text{NO}]}{\Delta t} = k[\text{NO}]^2$; second reaction, $-\frac{[\text{H}_2]}{\Delta t} = k[\text{H}_2][\text{N}_2\text{O}_2]$ (c) N₂O₂ is the intermediate. (d) Since [H₂] appears in the rate law, the second step must be slow relative to the first. **14.115** (a) $\text{Cl}_2(\text{g}) + \text{CHCl}_3(\text{g}) \longrightarrow \text{HCl}(\text{g}) + \text{CCl}_4(\text{g})$ (b) Cl(g), CCl₃(g) (c) reaction 1, unimolecular; reaction 2, bimolecular; reaction 3, bimolecular (d) Reaction 2 is rate determining. (e) Rate = $k[\text{CHCl}_3][\text{Cl}_2]^{1/2}$. **14.122** (a) $k = 8 \times 10^7 \text{ M}^{-1}\text{s}^{-1}$

(b) $\text{:}\ddot{\text{N}}=\ddot{\text{O}}\text{:}$

(c) NOF is bent with a bond angle of approximately 120°.

(e) The electron-deficient NO molecule is attracted to electron-rich F₂, so the driving force for formation of the transition state is greater than simple random collisions.

CHAPTER 15

15.1 $k_f > k_r$ (b) The equilibrium constant is greater than 1. **15.7** From the smallest to the largest equilibrium constant, (c) < (b) < (a). **15.11** K_c decreases as T increases, so the reaction is exothermic. **15.13** (a) $K_p = K_c = 8.1 \times 10^{-3}$. (b) Since $k_f < k_r$, in order for the two rates to be equal, [A] must be greater than [B], and the partial pressure of A is greater than the partial pressure of B. **15.15** (a) $K_c = \frac{[\text{N}_2\text{O}][\text{NO}_2]}{[\text{NO}]^3}$; homogeneous (b) $K_c = \frac{[\text{CS}_2][\text{H}_2]^4}{[\text{CH}_4][\text{H}_2\text{S}]^2}$; homogeneous (c) $K_c = \frac{[\text{CO}]^4}{[\text{Ni}(\text{CO})_4]}$; heterogeneous (d) $K_c = \frac{[\text{H}^+][\text{F}^-]}{[\text{HF}]}$; homogeneous (e) $K_c = \frac{[\text{Ag}^+]^2}{[\text{Zn}^{2+}]}$; heterogeneous (f) $K_c = \frac{[\text{H}^+][\text{OH}^-]}{[\text{H}_2\text{O}]}$; homogeneous (g) $K_c = \frac{[\text{H}^+][\text{OH}^-]}{[\text{H}_2\text{O}]}$; homogeneous **15.17** (a) Mostly reactants (b) mostly products **15.19** No, the equilibrium constant can never be a negative number. The equilibrium constant is a ratio of rate constants (or a ratio of concentrations), which are never negative. **15.21** $K_p = 1.0 \times 10^{-3}$ **15.23** (a) The equilibrium favors NO and Br₂ at this temperature. (b) $K_c = 77$ (c) $K_c = 8.8$ **15.25** (a) $K_p = 0.541$ (b) $K_p = 3.42$ (c) $K_c = 281$ **15.27** $K_c = 0.14$ **15.29** Pure solids

and liquids are normally excluded from equilibrium-constant expressions because their concentrations, the ratio of moles of a substance to volume occupied by the substance, are constant.

15.31 (a) $K_p = P_{\text{O}_2}$ (b) $K_c = [\text{Hg}(\text{soln})]^4[\text{O}_2(\text{soln})]$ **15.33** $K_c = 10.5$ **15.35** (a) $K_p = 51$ (b) $K_c = 2.1 \times 10^5$ **15.37** (a) $[\text{H}_2] = 0.012 \text{ M}$, $[\text{N}_2] = 0.019 \text{ M}$, $[\text{H}_2\text{O}] = 0.138 \text{ M}$ (b) $K_c = 653.7 = 7 \times 10^2$ **15.39** (a) $P_{\text{CO}_2} = 4.10 \text{ atm}$, $P_{\text{H}_2} = 2.05 \text{ atm}$, $P_{\text{H}_2\text{O}} = 3.28 \text{ atm}$ (b) $P_{\text{CO}_2} = 3.87 \text{ atm}$, $P_{\text{H}_2} = 1.82 \text{ atm}$, $P_{\text{CO}} = 0.23 \text{ atm}$ (c) $K_p = 0.11$ **15.41** $K_c = 2.0 \times 10^4$ **15.43** (a) A reaction quotient is the result of a general set of concentrations whereas the equilibrium constant requires equilibrium concentrations. (b) to the right (c) The concentrations used to calculate Q must be equilibrium concentrations. **15.45** (a) $Q = 1.1 \times 10^{-8}$, the reaction will proceed to the left. (b) $Q = 5.5 \times 10^{-12}$, the reaction will proceed to the right. (c) $Q = 2.19 \times 10^{-10}$, the mixture is at equilibrium. **15.47** $P_{\text{Cl}_2} = 5.0 \text{ atm}$ **15.49** (a) $[\text{Br}_2] = 0.00767 \text{ M}$, $[\text{Br}] = 0.00282 \text{ M}$, $0.0451 \text{ g Br}(\text{g})$ (b) $[\text{H}_2] = 0.014 \text{ M}$, $[\text{I}_2] = 0.00859 \text{ M}$, $[\text{HI}] = 0.081 \text{ M}$, 21 g HI **15.51** $[\text{NO}] = 0.002 \text{ M}$, $[\text{N}_2] = [\text{O}_2] = 0.087 \text{ M}$ **15.53** The equilibrium pressure of Br₂(g) is 0.416 atm. **15.55** (a) $[\text{Ca}^{2+}] = [\text{SO}_4^{2-}] = 4.9 \times 10^{-3} \text{ M}$ (b) A bit more than 1.0 g CaSO₄ is needed in order to have some undissolved CaSO₄(s) in equilibrium with 1.4 L of saturated solution. **15.57** $[\text{IBr}] = 0.223 \text{ M}$, $[\text{I}_2] = [\text{Br}_2] = 0.0133 \text{ M}$ **15.59** (a) $P_{\text{CH}_3\text{I}} = P_{\text{HI}} = 0.422 \text{ torr}$, $P_{\text{CH}_4} = 104.7 \text{ torr}$, $P_{\text{I}_2} = 7.54 \text{ torr}$ **15.61** (a) Shift equilibrium to the right (b) decrease the value of K (c) shift equilibrium to the left (d) no effect (e) no effect (f) shift equilibrium to the right **15.63** (a) No effect (b) no effect (c) no effect (d) increase equilibrium constant (e) no effect **15.65** (a) $\Delta H^\circ = -155.7 \text{ kJ}$ (b) The reaction is exothermic, so the equilibrium constant will decrease with increasing temperature. (c) Δn does not equal zero, so a change in volume at constant temperature will affect the fraction of products in the equilibrium mixture. **15.67** An increase in pressure favors formation of ozone. **15.71** $K_p = 24.7$; $K_c = 3.67 \times 10^{-3}$ **15.74** (a) $P_{\text{Br}_2} = 1.61 \text{ atm}$, $P_{\text{NO}} = 0.628 \text{ atm}$, $P_{\text{NOBr}} = 0.179 \text{ atm}$; $K_c = 0.0643$ (b) $P_t = 0.968 \text{ atm}$ (c) 10.49 g NOBr **15.77** At equilibrium, $P_{\text{IBr}} = 0.21 \text{ atm}$, $P_{\text{I}_2} = P_{\text{Br}_2} = 1.9 \times 10^{-3} \text{ atm}$ **15.80** $K_p = 4.33$, $K_c = 0.0480$ **15.83** $[\text{CO}_2] = [\text{H}_2] = 0.264 \text{ M}$, $[\text{CO}] = [\text{H}_2\text{O}] = 0.236 \text{ M}$ **15.87** (a) 26% of the CCl₄ is converted to C and Cl₂. (b) $P_{\text{CCl}_4} = 1.47 \text{ atm}$, $P_{\text{Cl}_2} = 1.06 \text{ atm}$ **15.91** $Q = 8 \times 10^{-6}$. $Q > K_p$, so the system is not at equilibrium; it will shift left to attain equilibrium. A catalyst that speeds up the reaction and thereby promotes the attainment of equilibrium would decrease the CO concentration in the exhaust. **15.93** At equilibrium, $[\text{H}_6\text{IO}_4^-] = 0.0015 \text{ M}$ **15.97** At 850 °C, $K_p = 14.1$; at 950 °C, $K_p = 73.8$; at 1050 °C, $K_p = 2.7 \times 10^2$; at 1200 °C, $K_p = 1.7 \times 10^3$. Because K increases with increasing temperature, the reaction is endothermic.

CHAPTER 16

16.1 (a) HX, the H⁺ donor, is the Brønsted–Lowry acid. NH₃, the H⁺ acceptor, is the Brønsted–Lowry base. (b) HX, the electron pair acceptor, is the Lewis acid. NH₃, the electron pair donor, is the Lewis base. **16.3** (a) HY is a strong acid. There are no neutral HY molecules in solution, only H⁺ cations and Y⁻ anions. (b) HX has the smallest K_a value. It has most neutral acid molecules and fewest ions. (c) HX has fewest H⁺ and highest pH. **16.5** (a) True. (b) False. Methyl orange turns yellow at a pH slightly greater than 4, so solution B could be at any pH greater than 4. (c) True. **16.7** (a) Molecule A, NH₂OH (hydroxyl amine), acts as a base. Molecule A is an H⁺ acceptor because of the nonbonded electron pair on the N atom of the amine (—NH₂) group, not because it contains an —OH group. (b) Molecule B, HCOOH (formic acid), acts as an acid. The molecule contains a —COOH group where the H atom bonded to O is ionizable and HCOOH is an H⁺ donor. (c) Molecule C, CH₃OH (methanol), is an organic alcohol. The H atom bonded to O is not ionizable, and the —OH group does not dissociate in aqueous solution; it is neither an acid nor a base. **16.9** (a) Molecule (b) is more acidic because its

conjugate base is resonance-stabilized and the ionization equilibrium favors the more stable products. (b) Increasing the electronegativity of X increases the strength of both acids. As X becomes more electronegative and attracts more electron density, the O—H bond becomes weaker, more polar, and more likely to be ionized. An electronegative X group also stabilizes the anionic conjugate base, causing the ionization equilibrium to favor products and the value of K_a to increase.

16.11 Solutions of HCl and H_2SO_4 conduct electricity, taste sour, turn litmus paper red (are acidic), neutralize solutions of bases, and react with active metals to form $H_2(g)$. HCl and H_2SO_4 solutions have these properties in common because both compounds are strong acids. That is, they both ionize completely in H_2O to form $H^+(aq)$ and an anion. (HSO_4^- is not completely ionized, but the first ionization step for H_2SO_4 is complete.) The presence of ions enables the solutions to conduct electricity; the presence of $H^+(aq)$ in excess of $1 \times 10^{-7} M$ accounts for all other properties listed. **16.13** (a) The Arrhenius definition of an acid is confined to aqueous solution; the Brønsted–Lowry definition applies to any physical state. (b) HCl is the Brønsted–Lowry acid; NH_3 is the Brønsted–Lowry base. **16.15** (a) (i) IO_3^- (ii) NH_3 (b) (i) OH^- (ii) H_3PO_4

16.17

Acid	+	Base	\rightleftharpoons	Conjugate Acid	+	Conjugate Base
(a) $NH_4^+(aq)$		$CN^-(aq)$		$HCN(aq)$		$NH_3(aq)$
(b) $H_2O(l)$		$(CH_3)_3N(aq)$		$(CH_3)_3NH^+(aq)$		$OH^-(aq)$
(c) $HCOOH(aq)$		$PO_4^{3-}(aq)$		$HPO_4^{2-}(aq)$		$HCOO^-(aq)$

16.19 (a) Acid:

(b) $H_2C_2O_4$ is the conjugate acid of $HC_2O_4^-$. $C_2O_4^{2-}$ is the conjugate base of $HC_2O_4^-$. **16.21** (a) CH_3COO^- , weak base; CH_3COOH , weak acid (b) HCO_3^- , weak base; H_2CO_3 , weak acid (c) O_2^{2-} , strong base; OH^- , strong base (d) Cl^- , negligible base; HCl, strong acid (e) NH_3 , weak base; NH_4^+ , weak acid

16.23 (a) HBr. It is one of the seven strong acids. (b) F^- . HCl is a stronger acid than HF, so F^- is the stronger conjugate base. **16.25** (a) $OH^-(aq) + OH^-(aq)$, the equilibrium lies to the right. (b) $H_2S(aq) + CH_3COO^-(aq)$, the equilibrium lies to the right. (c) $HNO_3(aq) + OH^-(aq)$, the equilibrium lies to the left. **16.27** (a) No. In pure water, the only source of H^+ is the autoionization reaction, which produces equal concentrations of H^+ and OH^- . As the temperature of water changes, the value of K_w changes, and the pH at which $[H^+] = [OH^-]$ changes.

16.29 (a) $[H^+] = 2.2 \times 10^{-11} M$, basic (b) $[H^+] = 1.1 \times 10^{-6} M$, acidic (c) $[H^+] = 1.0 \times 10^{-8} M$, basic **16.31** $[H^+] = [OH^-] = 3.5 \times 10^{-8} M$ **16.33** (a) $[H^+]$ changes by a factor of 100. (b) $[H^+]$ changes by a factor of 3.2 **16.35** (a) $[H^+]$ decreases, pH increases (b) The pH is between 3 and 4. By calculation, pH = 3.2; the solution is acidic. (c) pH = 5.2 is between pH 5 and pH 6, closer to pH = 5. A good estimate is $7 \times 10^{-6} M H^+$ and $3 \times 10^{-9} M OH^-$. By calculation, $[H^+] = 6 \times 10^{-6} M$ and $[OH^-] = 2 \times 10^{-9} M$.

16.37

$[H^+]$	$[OH^-]$	pH	pOH	Acidic or Basic
$7.5 \times 10^{-3} M$	$1.3 \times 10^{-12} M$	2.12	11.88	acidic
$2.8 \times 10^{-5} M$	$3.6 \times 10^{-10} M$	4.56	9.44	acidic
$5.6 \times 10^{-9} M$	$1.8 \times 10^{-6} M$	8.25	5.75	basic
$5.0 \times 10^{-9} M$	$2.0 \times 10^{-6} M$	8.30	5.70	basic

16.39 $[H^+] = 4.0 \times 10^{-8} M$, $[OH^-] = 6.0 \times 10^{-7} M$, pOH = 6.22

16.41 (a) A strong acid is completely ionized in aqueous solution.

(b) $[H^+] = 0.500 M$ (c) HCl, HBr, HI **16.43** (a) $[H^+] = 8.5 \times 10^{-3} M$,

pH = 2.07 (b) $[H^+] = 0.0419 M$, pH = 1.377 (c) $[H^+] = 0.0250 M$,

pH = 1.602 (d) $[H^+] = 0.167 M$, pH = 0.778 **16.45** (a)

$[OH^-] = 3.0 \times 10^{-3} M$, pH = 11.48 (b) $[OH^-] = 0.3758 M$,

pH = 13.5750 (c) $[OH^-] = 8.75 \times 10^{-5} M$, pH = 9.942 (d)

$[OH^-] = 0.17 M$, pH = 13.23 **16.47** $3.2 \times 10^{-3} M NaOH$ **16.49**

(a) $HBrO_2(aq) \rightleftharpoons H^+(aq) + BrO_2^-(aq)$, $K_a = [H^+][BrO_2^-]/$

$[HBrO_2]$; $HBrO_2(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + BrO_2^-(aq)$,

$K_a = [H_3O^+][BrO_2^-]/[HBrO_2]$ (b) $C_2H_5COOH(aq) \rightleftharpoons H^+(aq) +$

$C_2H_5COO^-(aq)$, $K_a = [H^+][C_2H_5COO^-]/[C_2H_5COOH]$;

$C_2H_5COOH(aq) + H_2O(l) \rightleftharpoons H_3O^+(aq) + C_2H_5COO^-(aq)$,

$K_a = [H_3O^+][C_2H_5COO^-]/[C_2H_5COOH]$ **16.51** $K_a = 1.4 \times 10^{-4}$

16.53 $[H^+] = [ClCH_2COO^-] = 0.0110 M$, $[ClCH_2COOH] = 0.089 M$

, $K_a = 1.4 \times 10^{-3}$ **16.55** $0.089 M CH_3COOH$ **16.57** $[H^+] =$

$[C_6H_5COO^-] = 1.8 \times 10^{-3} M$, $[C_6H_5COOH] = 0.048 M$

16.59 (a) $[H^+] = 1.1 \times 10^{-3} M$, pH = 2.95

(b) $[H^+] = 1.7 \times 10^{-4} M$, pH = 3.76 (c) $[OH^-] = 1.4 \times 10^{-5} M$,

pH = 9.15 **16.61** $[H^+] = 2.0 \times 10^{-2} M$, pH = 1.71 **16.63** (a)

$[H^+] = 2.8 \times 10^{-3} M$, 0.69% ionization (b) $[H^+] = 1.4 \times 10^{-3} M$,

1.4% ionization (c) $[H^+] = 8.7 \times 10^{-4} M$, 2.2% ionization

16.65 $HX(aq) \rightleftharpoons H^+(aq) + X^-(aq)$; $K_a = [H^+][X^-]/[HX]$. Assume that the percent of acid that ionizes is small. Let $[H^+] = [X^-] = y$,

$K_a = y^2/[HX]$; $y = K_a^{1/2}[HX]^{1/2}$. Percent ionization = $y/[HX] \times 100$.

Substituting for y , percent ionization = $100 K_a^{1/2}[HX]^{1/2}/[HX]$ or

$100 K_a^{1/2}/[HX]^{1/2}$. That is, percent ionization varies inversely as the

square root of the concentration of HX. **16.67** $[H^+] = 5.1 \times 10^{-3} M$,

pH = 2.29, $[C_6H_5O_7^{3-}] = 1.3 \times 10^{-9} M$. The approximation that

the first ionization is less than 5% of the total acid concentration is not

valid; the quadratic equation must be solved. The $[H^+]$ produced from

the second and third ionizations is small with respect to that present

from the first step; the second and third ionizations can be neglected

when calculating the $[H^+]$ and pH. $[C_6H_5O_7^{3-}]$ is much less than $[H^+]$.

16.69 (a) $HONH_3^+$ (b) When hydroxylamine acts as a base, the nitrogen

atom accepts a proton. (c) In hydroxylamine, O and N are the atoms with

nonbonding electron pairs; in the neutral molecule both have zero formal

charges. Nitrogen is less electronegative than oxygen and more likely to

share a lone pair of electrons with an incoming (and electron-deficient)

H^+ . The resulting cation with the +1 formal charge on N is more stable

than the one with the +1 formal charge on O. **16.71** (a)

$(CH_3)_2NH(aq) + H_2O(l) \rightleftharpoons (CH_3)_2NH_2^+(aq) +$

$OH^-(aq)$; $K_b = [(CH_3)_2NH_2^+][OH^-]/[(CH_3)_2NH]$

(b) $CO_3^{2-}(aq) + H_2O(l) \rightleftharpoons HCO_3^-(aq) + OH^-(aq)$;

$K_b = [HCO_3^-][OH^-]/[CO_3^{2-}]$ (c) $HCOO^-(aq) + H_2O(l) \rightleftharpoons$

$HCOOH(aq) + OH^-(aq)$ $K_b = [HCOOH][OH^-]/[HCOO^-]$

16.73 From the quadratic formula, $[OH^-] = 6.6 \times 10^{-3} M$,

pH = 11.82. **16.75** (a) $[C_{10}H_{15}ON] = 0.033 M$, $[C_{10}H_{15}ONH^+] =$

$[OH^-] = 2.1 \times 10^{-3} M$ (b) $K_b = 1.4 \times 10^{-4}$ **16.77** (a) For a conjugate

acid/conjugate base pair such as $C_6H_5OH/C_6H_5O^-$, K_b for the conju-

gate base can always be calculated from K_a for the conjugate acid, so a separate

list of K_b values is not necessary. (b) $K_b = 7.7 \times 10^{-5}$ (c) Phenolate is

a stronger base than NH_3 . **16.79** (a) Acetic acid is stronger. (b) Hypochlorite

ion is the stronger base. (c) For CH_3COO^- , $K_b = 5.6 \times 10^{-10}$; for

ClO^- , $K_b = 3.3 \times 10^{-7}$. **16.81** (a) $[OH^-] = 6.3 \times 10^{-4} M$,

pH = 10.80 (b) $[OH^-] = 9.2 \times 10^{-5} M$, pH = 9.96 (c)

$[OH^-] = 3.3 \times 10^{-6} M$, pH = 8.52 **16.83** (a) Acidic (b) acidic (c)

basic (d) neutral (e) acidic **16.85** K_b for the anion of the unknown salt is

1.4×10^{-11} ; K_a for the conjugate acid is 7.1×10^{-4} . The conju-

gate acid is HF and the salt is NaF. **16.87** (a) As the electronegativity of the central atom (X) increases, the strength of the oxyacid increases. (b) As the number of nonprotonated oxygen atoms in the molecule increases, the strength of the oxyacid increases. **16.89** (a) HNO₃ is a stronger acid because it has one more nonprotonated oxygen atom and thus a higher oxidation number on N. (b) For binary hydrides, acid strength increases going down a family, so H₂S is a stronger acid than H₂O. (c) H₂SO₄ is a stronger acid because H⁺ is much more tightly held by the anion HSO₄⁻. (d) For oxyacids, the greater the electronegativity of the central atom, the stronger the acid, so H₂SO₄ is the stronger acid. (e) CCl₃COOH is stronger because the electronegative Cl atoms withdraw electron density from other parts of the molecule, which weakens the O—H bond and stabilizes the anionic conjugate base. Both effects favor increased ionization and acid strength. **16.91** (a) BrO⁻ (b) BrO⁻ (c) HPO₄²⁻ **16.93** (a) True (b) False. In a series of acids that have the same central atom, acid strength increases with the number of nonprotonated oxygen atoms bonded to the central atom. (c) False. H₂Te is a stronger acid than H₂S because the H—Te bond is longer, weaker, and more easily ionized than the H—S bond. **16.95** Yes. The Arrhenius definition of a base, an OH⁻(aq) donor, is most restrictive; the Brønsted definition, an H⁺ acceptor, is more general; and the Lewis definition, an electron-pair donor, is most general. Any substance that fits the narrow Arrhenius definition will fit the broader Brønsted and Lewis definitions. **16.97** (a) Acid, Fe(ClO₄)₃ or Fe³⁺; base, H₂O (b) Acid, H₂O; base, CN⁻ (c) Acid, BF₃; base, (CH₃)₃N (d) Acid, HIO; base, NH₂⁻ **16.99** (a) Cu²⁺, higher cation charge (b) Fe³⁺, higher cation charge (c) Al³⁺, smaller cation radius, same charge **16.101** (C₂H₅)₃N is a stronger base than NH₃ by virtue of its smaller pK_b. **16.104** K = 3.3 × 10⁷ **16.107** (a) For solutions with equal concentrations, the weaker acid will have a lower [H⁺] and higher pH. (b) The acid with K_a = 8 × 10⁻⁵ is the weaker acid, so it has the higher pH. (c) The base with pK_b = 4.5 is the stronger base, has the greater [OH⁻] and smaller [H⁺], so higher pH. **16.109** K_a = 1.4 × 10⁻⁵ **16.115** 6.0 × 10¹³ H⁺ ions **16.118** (a) To the precision of the reported data, the pH of rainwater 40 years ago was 5.4, no different from the pH today. With extra significant figures, [H⁺] = 3.61 × 10⁻⁶ M, pH = 5.443 (b) A 20.0-L bucket of today's rainwater contains 0.02 L (with extra significant figures, 0.0200 L) of dissolved CO₂.

The electron-domain geometry and molecular structure are trigonal planar. (b) The Al atom is electron deficient. It acts like a Lewis acid in order to complete its octet.

(d) The Lewis theory is most appropriate. H⁺ and AlCl₃ are both electron pair acceptors. **16.121** Rx 1, ΔH = 104 kJ; Rx 2, ΔH = -32 kJ. Reaction 2 is exothermic while reaction 1 is endothermic. For binary acids with heavy atoms (X) in the same family, the longer and weaker the H—X bond, the stronger the acid (and the more exothermic the ionization reaction). **16.124** (a) K(i) = 5.6 × 10³, K(ii) = 10 (b) Both (i) and (ii) have K > 1, so both could be written with a single arrow.

CHAPTER 17

17.1 The middle box has the highest pH. For equal amounts of acid HX, the greater the amount of conjugate base X⁻, the smaller the amount of H⁺ and the higher the pH. **17.4** (a) Drawing 3 (b) Drawing 1 (c) Drawing 2 **17.7** (a) The red curve corresponds to the more concentrated acid solution. (b) On the titration curve of a weak acid,

pH = pK_a at the volume halfway to the equivalence point. At this volume, the red curve has the smaller pK_a and the larger K_a. **17.10** (a) Q = 4.67 × 10⁻⁶; Q < K_{sp} and the solution is not saturated. (b) Ca(OH)₂ precipitate forms in beaker (iii). **17.13** (a) The extent of ionization of a weak electrolyte is decreased when a strong electrolyte containing an ion in common with the weak electrolyte is added to it. (b) NaNO₂ **17.15** (a) [H⁺] = 1.8 × 10⁻⁵ M, pH = 4.73 (b) [OH⁻] = 4.8 × 10⁻⁵ M, pH = 9.68 (c) [H⁺] = 1.4 × 10⁻⁵ M, pH = 4.87 **17.17** (a) 4.5% ionization (b) 0.018% ionization **17.19** In a mixture of CH₃COOH and CH₃COONa, CH₃COOH reacts with added base and CH₃COO⁻ combines with added acid, leaving [H⁺] relatively unchanged. Although HCl and Cl⁻ are a conjugate acid–base pair, Cl⁻ has no tendency to combine with added acid to form undissociated HCl. Any added acid simply increases [H⁺] in an HCl—NaCl mixture. **17.21** (a) pH = 3.82 (b) pH = 3.96 **17.23** (a) pH = 5.26 (b) Na⁺(aq) + CH₃COO⁻(aq) + H⁺(aq) + Cl⁻(aq) →

(c) CH₃COOH(aq) + Na⁺(aq) + OH⁻(aq) → CH₃COO⁻(aq) + H₂O(l) + Na⁺(aq) **17.25** (a) pH = 1.58 (b) 36 g NaF **17.27** (a) pH = 4.86 (b) pH = 5.0 (c) pH = 4.71 **17.29** (a) [HCO₃⁻]/[H₂CO₃] = 11 (b) [HCO₃⁻]/[H₂CO₃] = 5.4 **17.31** 360 mL of 0.10 M HCOONa, 640 mL of 0.10 M HCOOH **17.33** (a) Curve B (b) pH at the approximate equivalence point of curve A = 8.0, pH at the approximate equivalence point of curve B = 7.0 (c) For equal volumes of A and B, the concentration of acid B is greater, since it requires a larger volume of base to reach the equivalence point. **17.35** (a) False (b) true (c) true **17.37** (a) Above pH 7 (b) below pH 7 (c) at pH 7 **17.39** The second color change of Thymol blue is in the correct pH range to show the equivalence point of the titration of a weak acid with a strong base. **17.41** (a) 42.4 mL NaOH soln (b) 35.0 mL NaOH soln (c) 29.8 mL NaOH soln **17.43** (a) pH = 1.54 (b) pH = 3.30 (c) pH = 7.00 (d) pH = 10.69 (e) pH = 12.74 **17.45** (a) pH = 2.78 (b) pH = 4.74 (c) pH = 6.58 (d) pH = 8.81 (e) pH = 11.03 (f) pH = 12.42 **17.47** (a) pH = 7.00 (b) [HONH₃⁺] = 0.100 M, pH = 3.52 (c) [C₆H₅NH₃⁺] = 0.100 M, pH = 2.82 **17.49** (a) The concentration of undissolved solid does not appear in the solubility product expression because it is constant. (b) K_{sp} = [Ag⁺][I⁻]; K_{sp} = [Sr²⁺][SO₄²⁻]; K_{sp} = [Fe²⁺][OH⁻]²; K_{sp} = [Hg₂²⁺][Br⁻]² **17.51** (a) K_{sp} = 7.63 × 10⁻⁹ (b) K_{sp} = 2.7 × 10⁻⁹ (c) 5.3 × 10⁻⁴ mol Ba(IO₃)₂/L

17.53 K_{sp} = 2.3 × 10⁻⁹ **17.55** (a) 7.1 × 10⁻⁷ mol AgBr/L (b) 1.7 × 10⁻¹¹ mol AgBr/L (c) 5.0 × 10⁻¹² mol AgBr/L **17.57** (a) The amount of CaF₂(s) on the bottom of the beaker increases. (b) The [Ca²⁺] in solution increases. (c) The [F⁻] in solution decreases. **17.59** (a) 1.4 × 10³ g Mn(OH)₂/L (b) 0.014 g/L (c) 3.6 × 10⁻⁷ g/L **17.61** More soluble in acid: (a) ZnCO₃ (b) ZnS (d) AgCN (e) Ba₃(PO₄)₂ **17.63** [Ni²⁺] = 1 × 10⁻⁸ M **17.65** (a) 9.1 × 10⁻⁹ mol AgI/L pure water (b) K = K_{sp} × K_f = 8 × 10⁴ (c) 0.0500 mol AgI/L 0.100 M NaCN **17.67** (a) Q < K_{sp}; no Ca(OH)₂ precipitates (b) Q < K_{sp}; no Ag₂SO₄ precipitates **17.69** pH = 11.5 **17.71** AgI will precipitate first, at [I⁻] = 4.2 × 10⁻¹³ M. **17.73** AgCl will precipitate first. **17.75** The first two experiments eliminate group 1 and 2 ions (Figure 17.23). The absence of insoluble phosphate precipitates in the filtrate from the third experiment rules out group 4 ions. The ions that might be in the sample are those from group 3, Al³⁺, Fe³⁺, Cr³⁺, Zn²⁺, Ni²⁺, Mn²⁺, or Co²⁺, and from group 5, NH₄⁺, Na⁺, or K⁺. **17.77** (a) Make the solution acidic with 0.2 M HCl; saturate with H₂S. CdS will precipitate; ZnS will not. (b) Add excess base; Fe(OH)₃(s) precipitates, but Cr³⁺ forms the soluble complex Cr(OH)₄⁻. (c) Add (NH₄)₂HPO₄; Mg²⁺ precipitates as MgNH₄PO₄; K⁺ remains soluble. (d) Add 6 M HCl; precipitate Ag⁺ as AgCl(s); Mn²⁺ remains soluble. **17.79** (a) Base is required to increase [PO₄³⁻] so that the solubility product of the metal phosphates of interest is exceeded and the phosphate salts precipitate. (b) K_{sp} for the cations in group 3 is much larger, and so to exceed K_{sp}, a higher [S²⁻] is required. (c) They should all redissolve in strongly acidic solution.

17.81 $\text{pOH} = \text{p}K_b + \log\{\frac{[\text{BH}^-]}{[\text{B}]}\}$ **17.83** (a) $\text{pH} = 3.171$ (b) $\text{pH} = 2.938$ (c) $\text{pH} = 12.862$ **17.86** (a) pH of buffer A = pH of buffer B = 3.74. For buffers containing the same conjugate acid and base components, the pH is determined by the ratio of concentrations of conjugate acid and base. Buffers A and B have the same ratio of concentrations, so their pH values are equal. (b) Buffer capacity is determined by the absolute amount of buffer components available to absorb strong acid or strong base. Buffer A has the greater capacity because it contains the greater absolute concentrations of HCOOH and HCOO^- . (c) Buffer A: $\text{pH} = 3.74$, $\Delta\text{pH} = 0.00$; buffer B: $\text{pH} = 3.66$, $\Delta\text{pH} = -0.12$ (d) Buffer A: $\text{pH} = 3.74$, $\Delta\text{pH} = 0.00$; buffer B: $\text{pH} = 2.74$, $\Delta\text{pH} = -1.00$ (e) The results of parts (c) and (d) are quantitative confirmation that buffer A has a significantly greater capacity than buffer B. **17.88** (a) molar mass = 82.2 g/mol (b) $K_a = 3.8 \times 10^{-7}$ **17.90** At the halfway point, $\text{mol HA} = \text{mol A}^-$ and $[\text{HA}] = [\text{A}^-]$.

$$\text{pH} = \text{p}K_a + \log \frac{[\text{conj. base}]}{[\text{conj. acid}]} = \text{p}K_a + \log \frac{[\text{A}^-]}{[\text{HA}^-]}$$

If $[\text{A}^-]/[\text{HA}] = 1$,

$\log(1) = 0$ and $\text{pH} = \text{p}K_a$ of the weak acid being titrated. **17.92** $\text{pH} = 7.75$ **17.93** 1.6 L of 1.0 M NaOH **17.96** (a) CdS (b) BaCrO_4 (c) NiCO_3 (d) Ag_2SO_4 **17.100** The solubility of $\text{Mg}(\text{OH})_2$ in 0.50 M NH_4Cl is 0.11 mol/L **17.101** $[\text{KMnO}_4] = [\text{MnO}_4^-] = 0.11 \text{ M}$ **17.104** $[\text{OH}^-] = 1.7 \times 10^{-11} \text{ M}$, pH of the buffer = 3.22 **17.107** (a) The molar solubility of $\text{Cd}(\text{OH})_2$ is $1.8 \times 10^{-5} \text{ mol/L}$. (b) The initial concentration of NaBr required to increase the molar solubility of $\text{Cd}(\text{OH})_2$ to $1.0 \times 10^{-3} \text{ mol/L}$ is 2 M. **17.108** (a) $\text{H}^+(\text{aq}) + \text{HCOO}^-(\text{aq}) \longrightarrow \text{HCOOH}(\text{aq})$ (b) $K = 5.6 \times 10^3$ (c) $[\text{Na}^+] = [\text{Cl}^-] = 0.075 \text{ M}$, $[\text{H}^+] = [\text{HCOO}^-] = 3.7 \times 10^{-3} \text{ M}$, $[\text{HCOOH}] = 0.071 \text{ M}$ **17.114** $[\text{Sr}^{2+}] = [\text{SO}_4^{2-}] = 5.7 \times 10^{-4} \text{ M}$, $K_{\text{sp}} = 3.2 \times 10^{-7}$

CHAPTER 18

18.1 (a) A greater volume than 22.4 L (b) The gas will occupy more volume at 85 km than at 50 km. (c) We expect gases to behave most ideally in the thermosphere, around the stratopause and in the troposphere at low altitude. **18.6** Salt water contains high concentrations of dissolved salts and solids. It includes the world ocean (97.2% of all water, approximately 35,000 ppm of dissolved salts) and brackish or salty water (0.1% of all water). Freshwater (0.6% of all water on earth) refers to natural waters that have low concentrations (less than 500 ppm) of dissolved salts and solids. It includes the waters of lakes, rivers, ponds, and streams. Groundwater is freshwater that is under the soil. It resides in aquifers, porous rock that holds water, and composes 20% of the world's freshwater. **18.9** The basic goals of green chemistry are to minimize or eliminate solvents and waste, generate nontoxic waste, be energy efficient, employ renewable starting materials, and take advantage of catalysts that enable the use of safe and common reagents. **18.11** (a) Its temperature profile (b) troposphere, 0 to 12 km; stratosphere, 12 to 50 km; mesosphere, 50 to 85 km; thermosphere, 85 to 110 km **18.13** (a) The partial pressure of O_3 is $3.0 \times 10^{-7} \text{ atm}$ ($2.2 \times 10^{-4} \text{ torr}$). (b) $7.3 \times 10^{15} \text{ O}_3$ molecules/1.0 L air **18.15** $8.6 \times 10^{16} \text{ CO}$ molecules/1.0 L air **18.17** (a) 570 nm (b) visible electromagnetic radiation **18.19** (a) Photodissociation is cleavage of a bond such that two neutral species are produced. Photoionization is absorption of a photon with sufficient energy to eject an electron, producing an ion and the ejected electron. (b) Photoionization of O_2 requires 1205 kJ/mol. Photodissociation requires only 495 kJ/mol. At lower elevations, high-energy short-wavelength solar radiation has already been absorbed. Below 90 km, the increased concentration of O_2 and the availability of longer-wavelength radiation cause the photodissociation process to dominate. **18.21** Ozone depletion reactions, which involve only O_3 , O_2 , or O (oxidation state = 0), do not involve a change in oxidation state for oxygen atoms. Reactions involving ClO and one of the oxygen species with a zero oxidation state do involve a change in the oxidation state of oxygen atoms. **18.23** (a) A chlorofluorocarbon is a compound that contains chlorine, fluorine, and

carbon, while a hydrofluorocarbon is a compound that contains hydrogen, fluorine, and carbon. An HFC contains hydrogen in place of the chlorine present in a CFC. (b) HFCs are potentially less harmful than CFCs because their photodissociation does not produce Cl atoms, which catalyze the destruction of ozone. **18.25** (a) The C—F bond requires more energy for dissociation than the C—Cl bond and is not readily cleaved by the available wavelengths of UV light. (b) Chlorine is present as chlorine atoms and chlorine oxide molecules, Cl and ClO, respectively. **18.27** (a) Methane, CH_4 , arises from decomposition of organic matter by certain microorganisms; it also escapes from underground gas deposits. (b) SO_2 is released in volcanic gases and also is produced by bacterial action on decomposing vegetable and animal matter. (c) Nitric oxide, NO, results from oxidation of decomposing organic matter and is formed in lightning flashes. **18.29** (a) $\text{H}_2\text{SO}_4(\text{aq}) + \text{CaCO}_3(\text{s}) \longrightarrow \text{CaSO}_4(\text{s}) + \text{H}_2\text{O}(\text{l}) + \text{CO}_2(\text{g})$ (b) The $\text{CaSO}_4(\text{s})$ would be much less reactive with acidic solution, since it would require a strongly acidic solution to shift the relevant equilibrium to the right: $\text{CaSO}_4(\text{s}) + 2\text{H}^+(\text{aq}) \rightleftharpoons \text{Ca}^{2+}(\text{aq}) + 2\text{HSO}_4^-(\text{aq})$. CaSO_4 would protect CaCO_3 from attack by acid rain, but it would not provide the structural strength of limestone. **18.31** (a) Ultraviolet (b) 357 kJ/mol (c) The average C—H bond energy from Table 8.4 is 413 kJ/mol. The C—H bond energy in CH_2O , 357 kJ/mol, is less than the “average” C—H bond energy.

(d)

18.33 Incoming and outgoing energies are in different regions of the electromagnetic spectrum. CO_2 is transparent to incoming visible radiation but absorbs outgoing infrared radiation. **18.35** 0.099 M Na^+ **18.37** (a) $3.22 \times 10^3 \text{ g H}_2\text{O}$ (b) The final temperature is 43.4°C. **18.39** $4.361 \times 10^5 \text{ g CaO}$ **18.41** (a) Groundwater is freshwater (less than 500 ppm total salt content) that is under the soil; it composes 20% of the world's freshwater. (b) An aquifer is a layer of porous rock that holds groundwater. **18.43** The minimum pressure required to initiate reverse osmosis is greater than 5.1 atm. **18.45** (a) $\text{CO}_2(\text{g})$, HCO_3^- , $\text{H}_2\text{O}(\text{l})$, SO_4^{2-} , NO_3^- , HPO_4^{2-} , H_2PO_4^- (b) $\text{CH}_4(\text{g})$, $\text{H}_2\text{S}(\text{g})$, $\text{NH}_3(\text{g})$, $\text{PH}_3(\text{g})$ **18.47** 25.1 g O_2 **18.49** $\text{Mg}^{2+}(\text{aq}) + \text{Ca}(\text{OH})_2(\text{s}) \longrightarrow \text{Mg}(\text{OH})_2(\text{s}) + \text{Ca}^{2+}(\text{aq})$ **18.51** 0.42 mol $\text{Ca}(\text{OH})_2$, 0.18 mol Na_2CO_3 **18.53** $4 \text{ FeSO}_4(\text{aq}) + \text{O}_2(\text{aq}) + 2 \text{ H}_2\text{O}(\text{l}) \longrightarrow 4 \text{ Fe}^{3+}(\text{aq}) + 4 \text{ OH}^-(\text{aq}) + 4 \text{ SO}_4^{2-}(\text{aq})$; $\text{Fe}^{3+}(\text{aq}) + 3 \text{ HCO}_3^-(\text{aq}) \longrightarrow \text{Fe}(\text{OH})_3(\text{s}) + 3 \text{ CO}_2(\text{g})$ **18.55** (a) Trihalomethanes are the by-products of water chlorination; they contain one central carbon atom bound to one hydrogen and three halogen atoms.

(b)

18.57 The fewer steps in a process, the less waste is generated. Processes with fewer steps require less energy at the site of the process and for subsequent cleanup or disposal of waste. **18.59** (a) H_2O (b) It is better to prevent waste than to treat it. Atom economy. Less hazardous chemical synthesis and inherently safer for accident prevention. Catalysis and design for energy efficiency. Raw materials should be renewable. **18.61** (a) Water as a solvent, by criteria 5, 7, and 12. (b) Reaction temperature of 500 K, by criteria 6, 12, and 1. (c) Sodium chloride as a by-product, according to criteria 1, 3, and 12. **18.66** Multiply Equation 18.7 by a factor of 2; then add it to Equation 18.9. 2 Cl(g) and 2 ClO(g) cancel from each side of the resulting equation to produce Equation 18.10. **18.69** Although HFCs have long lifetimes in the stratosphere, it is infrequent that light with energy sufficient to dissociate a C—F bond will reach an HFC molecule. F atoms, the bad actors in ozone destruction, are much less likely than Cl atoms to be produced by photodissociation in the stratosphere. **18.71** The formation of NO(g) is endothermic, so K increases with increasing

temperature. The oxidation of $\text{NO}(g)$ to $\text{NO}_2(g)$ is exothermic, so the value of K decreases with increasing temperature. **18.75** $7.1 \times 10^8 \text{ m}^2$ **18.77** (a) CO_3^{2-} is a relatively strong Brønsted-Lowry base and produces OH^- in aqueous solution. If $[\text{OH}^-(aq)]$ is sufficient for the reaction quotient to exceed K_{sp} for $\text{Mg}(\text{OH})_2$, the solid will precipitate. (b) At these ion concentrations, $Q > K_{sp}$ and $\text{Mg}(\text{OH})_2$ will precipitate. **18.81** (a) $2.5 \times 10^7 \text{ ton CO}_2$, $4.2 \times 10^5 \text{ ton SO}_2$ (b) $4.3 \times 10^5 \text{ ton CaSO}_3$ **18.84** (a)

(b) 258 nm (c) The overall reaction is $\text{O}_3(g) + \text{O}(g) \longrightarrow 2 \text{O}_2(g)$. $\text{OH}(g)$ is the catalyst in the overall reaction because it is consumed and then reproduced. **18.86** The enthalpy change for the first step is -141 kJ , for the second step, -249 kJ , for the overall reaction, -390 kJ . **18.90** (a) $\text{Rate} = k[\text{O}_3][\text{H}]$ (b) $k_{\text{avg}} = 1.13 \times 10^{44} \text{ M}^{-1} \text{ s}^{-1}$ **18.95** (a) Process (i) is greener because it involves neither the toxic reactant phosgene nor the by-product HCl. (b) Reaction (i): C in CO_2 is linear with sp hybridization; C in $\text{R}-\text{N}=\text{C}=\text{O}$ is linear with sp hybridization; C in the urethane monomer is trigonal planar with sp^2 hybridization. Reaction (ii): C in COCl_2 is linear with sp^2 hybridization; C in $\text{R}-\text{N}=\text{C}=\text{O}$ is linear with sp hybridization; C in the urethane monomer is trigonal planar with sp^2 hybridization. (c) The greenest way to promote formation of the isocyanate is to remove by-product, either water or HCl, from the reaction mixture.

CHAPTER 19

19.1 (a)

(b) $\Delta H = 0$ for mixing ideal gases. ΔS is positive because the disorder of the system increases. (c) The process is spontaneous and therefore irreversible. (d) Since $\Delta H = 0$, the process does not affect the entropy of the surroundings. **19.4** ΔS is positive. **19.7** (a) At 300 K, $\Delta G = 0$, and the system is at equilibrium. (b) The reaction is spontaneous at temperatures above 300 K. **19.10** (a) The minimum in the plot is the equilibrium position of the reaction. (b) The quantity x is ΔG° . **19.11** Spontaneous: a, b, c, d; nonspontaneous: e **19.13** (a) $\text{NH}_4\text{NO}_3(s)$ dissolves in water, as in a chemical cold pack. Naphthalene (moth balls) sublimates at room temperature. (b) Melting of a solid is spontaneous above its melting point but nonspontaneous below its melting point. **19.15** (a) Endothermic (b) above 100°C (c) below 100°C (d) at 100°C **19.17** (a) For a reversible process, the forward and reverse changes occur by the same path. In a reversible process, both the system and the surroundings are restored to their original condition by exactly reversing the change. A reversible change produces the maximum amount of work. (b) There is no net change in the surroundings. (c) The vaporization of water to steam is reversible if it occurs at the boiling temperature of water for a specified external (atmospheric) pressure and if the required heat is added infinitely slowly. (d) No. Natural processes are spontaneous in the direction they occur and nonspontaneous in the opposite direction. By definition they are irreversible. **19.19** (a) If the ideal gas is contained in a closed system at constant volume, a decrease in external temperature leads to a decrease in both temperature and pressure of the gas. (b) If the ideal gas is contained in a closed system at constant pressure, a decrease in external temperature leads to a decrease in both temperature and volume of the gas. (c) No. ΔE is a state function. $\Delta E = q + w$; q and w are not state functions. Their values do depend on path, but their sum, ΔE , does not. **19.21** (a) An ice cube can melt reversibly at the conditions of temperature and pressure where the solid and liquid are in equilibrium. (b) We know that melting is a process that increases the energy of the system even though there is no change in temper-

ature. ΔE is not zero for the process. **19.23** (a) At constant temperature, $\Delta S = q_{\text{rev}}/T$, where q_{rev} is the heat that would be transferred if the process were reversible. (b) No. ΔS is a state function, so it is independent of path. **19.25** (a) Entropy increases. (b) 89.2 J/K **19.27** (a) For a spontaneous process, the entropy of the universe increases; for a reversible process, the entropy of the universe does not change. (b) For a reversible process, if the entropy of the system increases, the entropy of the surroundings must decrease by the same amount. (c) For a spontaneous process, the entropy of the universe must increase, so the entropy of the surroundings must decrease by less than 42 J/K . **19.29** (a) Positive ΔS (b) $\Delta S = 1.02 \text{ J/K}$ (c) Temperature need not be specified to calculate ΔS , as long as the expansion is isothermal. **19.31** (a) Yes, the expansion is spontaneous. (b) As the ideal gas expands into the vacuum, there is nothing for it to “push back,” so no work is done. Mathematically, $w = -P_{\text{ext}}\Delta V$. Since the gas expands into a vacuum, $P_{\text{ext}} = 0$ and $w = 0$. (c) The “driving force” for the expansion of the gas is the increase in entropy. **19.33** (a) An increase in temperature produces more available microstates for a system. (b) A decrease in volume produces fewer available microstates for a system. (c) Going from liquid to gas, the number of available microstates increases. **19.35** (a) ΔS is positive. (b) S of the system clearly increases in 19.11 (b) and (e); it clearly decreases in 19.9 (c). The entropy change is difficult to judge in 19.9 (a) and definition of the system in (d) is problematic. **19.37** S increases in (a) and (c); S decreases in (b). **19.39** (a) The entropy of a pure crystalline substance at absolute zero is zero. (b) In translational motion the entire molecule moves in a single direction; in rotational motion the molecule rotates or spins around a fixed axis. In vibrational motion the bonds within a molecule stretch and bend, but the average position of the atoms does not change.

19.41 (a) $\text{Ar}(g)$ (b) $\text{He}(g)$ at 1.5 atm (c) 1 mol of $\text{Ne}(g)$ in 15.0 L (d) $\text{CO}_2(g)$ **19.43** (a) $\Delta S < 0$ (b) $\Delta S > 0$ (c) $\Delta S < 0$ (d) $\Delta S \approx 0$ **19.45** (a)

(b) Boiling water, at 100°C , has a much larger entropy change than melting ice at 0°C . **19.47** (a) $\text{C}_2\text{H}_6(g)$ (b) $\text{CO}_2(g)$ **19.49** (a) $\text{Sc}(s)$, $34.6 \text{ J/mol}\cdot\text{K}$; $\text{Sc}(g)$, $174.7 \text{ J/mol}\cdot\text{K}$. In general, the gas phase of a substance has a larger S° than the solid phase because of the greater volume and motional freedom of the molecules. (b) $\text{NH}_3(g)$, $192.5 \text{ J/mol}\cdot\text{K}$; $\text{NH}_3(aq)$, $111.3 \text{ J/mol}\cdot\text{K}$. Molecules in the gas phase have more motional freedom than molecules in solution. (c) 1 mol of

$P_4(g)$, 280 J/K; 2 mol of $P_2(g)$, $2(218.1) = 436.2$ J/K. More particles have a greater motional energy (more available microstates). (d) C (diamond), 2.43 J/mol-K; C (graphite), 5.69 J/mol-K. The internal entropy in graphite is greater because there is translational freedom among planar sheets of C atoms, while there is very little freedom within the covalent-network diamond lattice. **19.51** For elements with similar structures, the heavier the atoms, the lower the vibrational frequencies at a given temperature. This means that more vibrations can be accessed at a particular temperature, resulting in greater absolute entropy for the heavier elements. **19.53** (a) $\Delta S^\circ = -120.5$ J/K. ΔS° is negative because there are fewer moles of gas in the products. (b) $\Delta S^\circ = +176.6$ J/K. ΔS° is positive because there are more moles of gas in the products. (c) $\Delta S^\circ = +152.39$ J/K. ΔS° is positive because the product contains more total particles and more moles of gas. (d) $\Delta S^\circ = +92.3$ J/K. ΔS° is positive because there are more moles of gas in the products. **19.55** (a) $\Delta G = \Delta H - T\Delta S$ (b) If ΔG is positive, the process is nonspontaneous, but the reverse process is spontaneous. (c) There is no relationship between ΔG and rate of reaction. **19.57** (a) Exothermic (b) ΔS° is negative; the reaction leads to a decrease in disorder. (c) $\Delta G^\circ = -9.9$ kJ (d) If all reactants and products are present in their standard states, the reaction is spontaneous in the forward direction at this temperature. **19.59** (a) $\Delta H^\circ = -537.22$ kJ, $\Delta S^\circ = 13.7$ J/K, $\Delta G^\circ = -541.40$ kJ, $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ = -541.31$ kJ (b) $\Delta H^\circ = -106.7$ kJ, $\Delta S^\circ = -142.2$ kJ, $\Delta G^\circ = -64.0$ kJ, $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ = -64.3$ kJ (c) $\Delta H^\circ = -508.3$ kJ, $\Delta S^\circ = -178$ kJ, $\Delta G^\circ = -465.8$ kJ, $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ = -455.1$ kJ. The discrepancy in ΔG° values is due to experimental uncertainties in the tabulated thermodynamic data. (d) $\Delta H^\circ = -165.9$ kJ, $\Delta S^\circ = 1.4$ kJ, $\Delta G^\circ = -166.2$ kJ, $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ = -166.3$ kJ **19.61** (a) $\Delta G^\circ = -140.0$ kJ, spontaneous (b) $\Delta G^\circ = +104.70$ kJ, nonspontaneous (c) $\Delta G^\circ = +146$ kJ, nonspontaneous (d) $\Delta G^\circ = -156.7$ kJ, spontaneous **19.63** (a) $2C_8H_{18}(l) + 25O_2(g) \longrightarrow 16CO_2(g) + 18H_2O(l)$ (b) Because ΔS° is positive, ΔG° is more negative than ΔH° . **19.65** (a) The forward reaction is spontaneous at low temperatures but becomes nonspontaneous at higher temperatures. (b) The reaction is nonspontaneous in the forward direction at all temperatures. (c) The forward reaction is nonspontaneous at low temperatures but becomes spontaneous at higher temperatures. **19.67** $\Delta S > 60.8$ J/K **19.69** (a) $T = 330$ K (b) nonspontaneous **19.71** (a) $\Delta H^\circ = 155.7$ kJ, $\Delta S^\circ = 171.4$ kJ. Since ΔS° is positive, ΔG° becomes more negative with increasing temperature. (b) $\Delta G^\circ = 19$ kJ. The reaction is not spontaneous under standard conditions at 800 K (c) $\Delta G^\circ = -15.7$ kJ. The reaction is spontaneous under standard conditions at 1000 K. **19.73** (a) $T_b = 79^\circ\text{C}$ (b) From the *Handbook of Chemistry and Physics*, 74th Edition, $T_b = 80.1^\circ\text{C}$. The values are remarkably close; the small difference is due to deviation from ideal behavior by $C_6H_6(g)$ and experimental uncertainty in the boiling point measurement and the thermodynamic data. **19.75** (a) $C_2H_2(g) + \frac{5}{2}O_2(g) \longrightarrow 2CO_2(g) + H_2O(l)$ (b) -1299.5 kJ of heat produced/mol C_2H_2 burned (c) $w_{\max} = -1235.1$ kJ/mol C_2H_2 **19.77** (a) ΔG becomes more negative. (b) ΔG becomes more positive. (c) ΔG becomes more positive. **19.79** (a) $\Delta G^\circ = -5.40$ kJ (b) $\Delta G = 0.30$ kJ **19.81** (a) $\Delta G^\circ = -16.77$ kJ, $K = 870$ (b) $\Delta G^\circ = 8.0$ kJ, $K = 0.039$ (c) $\Delta G^\circ = -497.9$ kJ, $K = 2 \times 10^{87}$ **19.83** $\Delta H^\circ = 269.3$ kJ, $\Delta S^\circ = 0.1719$ kJ/K (a) $P_{CO_2} = 6.0 \times 10^{-39}$ atm (b) $P_{CO_2} = 1.6 \times 10^{-4}$ atm **19.85** (a) $HNO_2(aq) \rightleftharpoons H^+(aq) + NO_2^-(aq)$ (b) $\Delta G^\circ = 19.1$ kJ (c) $\Delta G = 0$ at equilibrium (d) $\Delta G = -2.7$ kJ **19.87** (a) The thermodynamic quantities T , E , and S are state functions. (b) The quantities q and w depend on the path taken. (c) There is only one reversible path between states. (d) $\Delta E = q_{rev} + w_{max}$, $\Delta S = q_{rev}/T$. **19.91** (a) 16 arrangements (b) 1 arrangement (c) The gas will spontaneously adopt the state with the most possible arrangements for the molecules, the state with maximum disorder. **19.96** (a) For all three compounds listed, there are fewer moles of gaseous products than reactants in the formation reaction, so we expect ΔS_f° to be negative. If $\Delta G_f^\circ = \Delta H_f^\circ - T\Delta S_f^\circ$ and ΔS_f° is negative, $-T\Delta S_f^\circ$ is positive and ΔG_f° is more positive than

ΔH_f° . (b) In this reaction, there are more moles of gas in products, ΔS_f° is positive, $-T\Delta S_f^\circ$ is negative and ΔG_f° is more negative than ΔH_f° .

19.100 (a) $K = 4 \times 10^{15}$ (b) An increase in temperature will decrease the mole fraction of CH_3COOH at equilibrium. Elevated temperatures must be used to increase the speed of the reaction. (c) $K = 1$ at 836 K or 563°C . **19.104** (a) $\Delta G = 8.77$ kJ (b) $w_{\min} = 8.77$ kJ. In practice, a larger than minimum amount of work is required. **19.108** (a) Acetone, $\Delta S_{\text{vap}}^\circ = 88.4$ J/mol-K; dimethyl ether, $\Delta S_{\text{vap}}^\circ = 86.6$ J/mol-K; ethanol, $\Delta S_{\text{vap}}^\circ = 110$ J/mol-K; octane, $\Delta S_{\text{vap}}^\circ = 86.3$ J/mol-K; pyridine, $\Delta S_{\text{vap}}^\circ = 90.4$ J/mol-K. Ethanol does not obey Trouton's rule. (b) Hydrogen bonding (in ethanol and other liquids) leads to more ordering in the liquid state and a greater than usual increase in entropy upon vaporization. Liquids that experience hydrogen bonding are probably exceptions to Trouton's rule. (c) Owing to strong hydrogen bonding interactions, water probably does not obey Trouton's rule. $\Delta S_{\text{vap}}^\circ = 109.0$ J/mol-K. (d) ΔH_{vap} for $C_6H_5Cl \approx 36$ kJ/mol **19.113** (a) For any given total pressure, the condition of equal moles of the two gases can be achieved at some temperature. For individual gas pressures of 1 atm and a total pressure of 2 atm, the mixture is at equilibrium at 328.5 K or 55.5°C . (b) 333.0 K or 60°C (c) 374.2 K or 101.2°C (d) The reaction is endothermic, so an increase in the value of K as calculated in parts (a)–(c) should be accompanied by an increase in T .

CHAPTER 20

20.1 In a Brønsted–Lowry acid–base reaction, H^+ is transferred from the acid to the base. In a redox reaction, one or more electrons are transferred from the reductant to the oxidant. The greater the tendency of an acid to donate H^+ , the lesser the tendency of its conjugate base to accept H^+ . The stronger the acid, the weaker its conjugate base. Similarly, the greater the tendency of a reduced species to donate electrons, the lesser the tendency of the corresponding oxidized species to accept electrons. The stronger the reducing agent, the weaker the corresponding oxidizing agent. **20.4** (a) Add 1 M $A^{2+}(aq)$ to the beaker with the A(s) electrode. Add 1 M $B^{2+}(aq)$ to the beaker with the B(s) electrode. Add a salt bridge to enable the flow of ions from one compartment to the other. (b) The A electrode functions as the cathode. (c) Electrons flow through the external circuit from the anode to the cathode, from B to A in this cell. (d) $E_{\text{cell}}^\circ = 1.00$ V. **20.7** (a) The sign of ΔG° is positive. (b) The equilibrium constant is less than one. (c) No. An electrochemical cell based on this reaction cannot accomplish work on its surroundings. **20.9** (a) Line 1 (b) $E_{\text{red}} = E_{\text{red}}^\circ = 0.799$ V. **20.13** (a) Oxidation is the loss of electrons. (b) Electrons appear on the products' side (right side). (c) The oxidant is the reactant that is reduced. (d) An oxidizing agent is the substance that promotes oxidation; it is the oxidant. **20.15** (a) True (b) false (c) true **20.17** (a) I, +5 to 0; C, +2 to +4 (b) Hg, +2 to 0; N, -2 to 0 (c) N, +5 to +2; S, -2 to 0 (d) Cl, +4 to +3; O, -1 to 0 **20.19** (a) $TiCl_4(g) + 2Mg(l) \longrightarrow Ti(s) + 2MgCl_2(l)$ (b) $Mg(l)$ is oxidized; $TiCl_4(g)$ is reduced. (c) $Mg(l)$ is the reductant; $TiCl_4(g)$ is the oxidant. **20.21** (a) $Sn^{2+}(aq) \longrightarrow Sn^{4+}(aq) + 2e^-$, oxidation (b) $TiO_2(s) + 4H^+(aq) + 2e^- \longrightarrow Ti^{2+}(aq) + 2H_2O(l)$, reduction (c) $ClO_3^-(aq) + 6H^+(aq) + 6e^- \longrightarrow Cl^-(aq) + 3H_2O(l)$, reduction (d) $N_2(g) + 8H^+(aq) + 6e^- \longrightarrow 2NH_4^+(aq)$, reduction (e) $4OH^-(aq) \longrightarrow O_2(g) + 2H_2O(l) + 4e^-$, oxidation (f) $SO_3^{2-}(aq) + 2OH^-(aq) \longrightarrow SO_4^{2-}(aq) + H_2O(l) + 2e^-$, oxidation (g) $N_2(g) + 6H_2O(l) + 6e^- \longrightarrow 2NH_3(g) + 6OH^-(aq)$, reduction **20.23** (a) $Cr_2O_7^{2-}(aq) + I^-(aq) + 8H^+(aq) \longrightarrow 2Cr^{3+}(aq) + IO_3^-(aq) + 4H_2O(l)$; oxidizing agent, $Cr_2O_7^{2-}$; reducing agent, I^- (b) $4MnO_4^-(aq) + 5CH_3OH(aq) + 12H^+(aq) \longrightarrow 4Mn^{2+}(aq) + 5HCO_2H(aq) + 12H_2O(aq)$; oxidizing agent, MnO_4^- ; reducing agent, CH_3OH (c) $I_2(s) + 5OCl^-(aq) + H_2O(l) \longrightarrow 2IO_3^-(aq) + 5Cl^-(aq) + 2H^+(aq)$; oxidizing agent, OCl^- ; reducing agent, I_2 (d) $As_2O_3(s) +$

$2 \text{NO}_3^-(aq) + 2 \text{H}_2\text{O}(l) + 2 \text{H}^+(aq) \longrightarrow 2 \text{H}_3\text{AsO}_4(aq) + \text{N}_2\text{O}_3(aq)$; oxidizing agent, NO_3^- ; reducing agent, As_2O_3
 (e) $2 \text{MnO}_4^-(aq) + \text{Br}^-(aq) + \text{H}_2\text{O}(l) \longrightarrow 2 \text{MnO}_2(s) + \text{BrO}_3^-(aq) + 2 \text{OH}^-(aq)$; oxidizing agent, MnO_4^- ; reducing agent, Br^- (f) $\text{Pb}(\text{OH})_4^{2-}(aq) + \text{ClO}^-(aq) \longrightarrow \text{PbO}_2(s) + \text{Cl}^-(aq) + 2 \text{OH}^-(aq) + \text{H}_2\text{O}(l)$; oxidizing agent, ClO^- ; reducing agent, $\text{Pb}(\text{OH})_4^{2-}$
20.25 (a) The reaction $\text{Cu}^{2+}(aq) + \text{Zn}(s) \longrightarrow \text{Cu}(s) + \text{Zn}^{2+}(aq)$ is occurring in both figures. In Figure 20.3 the reactants are in contact, while in Figure 20.4 the oxidation half-reaction and reduction half-reaction are occurring in separate compartments. In Figure 20.3 the flow of electrons cannot be isolated or utilized; in Figure 20.4 electrical current is isolated and flows through the voltmeter. (b) Na^+ cations are drawn into the cathode compartment to maintain charge balance as Cu^{2+} ions are removed. **20.27** (a) $\text{Fe}(s)$ is oxidized, $\text{Ag}^+(aq)$ is reduced. (b) $\text{Ag}^+(aq) + e^- \longrightarrow \text{Ag}(s)$; $\text{Fe}(s) \longrightarrow \text{Fe}^{2+}(aq) + 2e^-$ (c) $\text{Fe}(s)$ is the anode, $\text{Ag}(s)$ is the cathode. (d) $\text{Fe}(s)$ is negative; $\text{Ag}(s)$ is positive. (e) Electrons flow from the Fe electrode (-) toward the Ag electrode (+). (f) Cations migrate toward the $\text{Ag}(s)$ cathode; anions migrate toward the $\text{Fe}(s)$ anode. **20.29** *Electromotive force*, emf, is the potential energy difference between an electron at the anode and an electron at the cathode of a voltaic cell. (b) One volt is the potential energy difference required to impart 1 J of energy to a charge of 1 coulomb. (c) *Cell potential*, E_{cell} , is the emf of an electrochemical cell.
20.31 (a) $2 \text{H}^+(aq) + 2e^- \longrightarrow \text{H}_2(g)$ (b) A standard hydrogen electrode, SHE, has components that are at standard conditions, 1 M $\text{H}^+(aq)$ and $\text{H}_2(g)$ at 1 atm. (c) The platinum foil in a SHE serves as an inert electron carrier and a solid reaction surface. **20.33** (a) A *standard reduction potential* is the relative potential of a reduction half-reaction measured at standard conditions. (b) $E_{\text{red}}^\circ = 0 \text{ V}$ **20.35** (a) $\text{Cr}^{2+}(aq) \longrightarrow \text{Cr}^{3+}(aq) + e^-$; $\text{Tl}^{3+}(aq) + 2e^- \longrightarrow \text{Tl}^+(aq)$ (b) $E_{\text{red}}^\circ = 0.78 \text{ V}$ (c)

20.37 (a) $E^\circ = 0.823 \text{ V}$ (b) $E^\circ = 1.89 \text{ V}$ (c) $E^\circ = 1.211 \text{ V}$ (d) $E^\circ = 0.62 \text{ V}$ **20.39** (a) $3 \text{Ag}^+(aq) + \text{Cr}(s) \longrightarrow 3 \text{Ag}(s) + \text{Cr}^{3+}(aq)$, $E^\circ = 1.54 \text{ V}$ (b) Two of the combinations have essentially equal E° values: $2 \text{Ag}^+(aq) + \text{Cu}(s) \longrightarrow 2 \text{Ag}(s) + \text{Cu}^{2+}(aq)$, $E^\circ = 0.462 \text{ V}$; $3 \text{Ni}^{2+}(aq) + 2 \text{Cr}(s) \longrightarrow 3 \text{Ni}(s) + 2 \text{Cr}^{3+}(aq)$, $E^\circ = 0.46 \text{ V}$ **20.41** (a) Anode, $\text{Sn}(s)$; cathode, $\text{Cu}(s)$. (b) The copper electrode gains mass as Cu is plated out, and the tin electrode loses mass as Sn is oxidized. (c) $\text{Cu}^{2+}(aq) + \text{Sn}(s) \longrightarrow \text{Cu}(s) + \text{Sn}^{2+}(aq)$. (d) $E^\circ = 0.473 \text{ V}$. **20.43** (a) $\text{Mg}(s)$ (b) $\text{Ca}(s)$ (c) $\text{H}_2(g)$ (d) $\text{BrO}_3^-(aq)$
20.45 (a) $\text{Cl}_2(aq)$, strong oxidant (b) $\text{MnO}_4^-(aq)$, acidic, strong oxidant (c) $\text{Ba}(s)$ strong reductant (d) $\text{Zn}(s)$, reductant
20.47 (a) $\text{Cu}^{2+}(aq) < \text{O}_2(g) < \text{Cr}_2\text{O}_7^{2-}(aq) < \text{Cl}_2(g) < \text{H}_2\text{O}_2(aq)$

(b) $\text{H}_2\text{O}_2(aq) < \text{I}^-(aq) < \text{Sn}^{2+}(aq) < \text{Zn}(s) < \text{Al}(s)$ **20.49** Al and $\text{H}_2\text{C}_2\text{O}_4$ **20.51** (a) $2 \text{Fe}^{2+}(aq) + \text{S}_2\text{O}_6^{2-}(aq) + 4 \text{H}^+(aq) \longrightarrow 2 \text{Fe}^{3+}(aq) + 2 \text{H}_2\text{SO}_3(aq)$; $2 \text{Fe}^{2+}(aq) + \text{N}_2\text{O}(aq) + 2 \text{H}^+(aq) \longrightarrow 2 \text{Fe}^{3+}(aq) + \text{N}_2(g) + \text{H}_2\text{O}(l)$; $\text{Fe}^{2+}(aq) + \text{VO}_2^+(aq) + 2 \text{H}^+(aq) \longrightarrow \text{Fe}^{3+}(aq) + \text{VO}^{2+}(aq) + \text{H}_2\text{O}(l)$ (b) $E^\circ = -0.17 \text{ V}$, $\Delta G^\circ = 33 \text{ kJ}$; $E^\circ = -2.54 \text{ V}$, $\Delta G^\circ = 4.90 \times 10^2 \text{ kJ}$; $E^\circ = 0.23 \text{ V}$, $\Delta G^\circ = -22 \text{ kJ}$
 (c) $K = 1.8 \times 10^{-6} = 10^{-6}$; $K = 1.2 \times 10^{-86} = 10^{-86}$;
 $K = 7.8 \times 10^3 = 8 \times 10^3$ **20.53** $\Delta G^\circ = 21.8 \text{ kJ}$, $E_{\text{cell}}^\circ = -0.113 \text{ V}$
20.55 (a) $E^\circ = 0.16 \text{ V}$, $K = 2.54 \times 10^5 = 3 \times 10^5$ (b) $E^\circ = 0.277 \text{ V}$, $K = 2.3 \times 10^9$ (c) $E^\circ = 0.45 \text{ V}$, $K = 1.5 \times 10^{75} = 10^{75}$
20.57 (a) $K = 9.8 \times 10^2$ (b) $K = 9.5 \times 10^5$ (c) $K = 9.3 \times 10^8$
20.59 (a) $w_{\text{max}} = -130 \text{ kJ/mol Sn}$ **20.61** (a) The Nernst equation is applicable when the components of an electrochemical cell are at nonstandard conditions. (b) $Q = 1$ (c) Q decreases and E increases **20.63** (a) E decreases (b) E decreases (c) E decreases (d) no effect
20.65 (a) $E^\circ = 0.48 \text{ V}$ (b) $E = 0.53 \text{ V}$ (c) $E = 0.46 \text{ V}$
20.67 (a) $E^\circ = 0.46 \text{ V}$ (b) $E = 0.37 \text{ V}$ **20.69** (a) The compartment with $[\text{Zn}^{2+}] = 1.00 \times 10^{-2} \text{ M}$ is the anode. (b) $E^\circ = 0$ (c) $E = 0.0668 \text{ V}$ (d) In the anode compartment $[\text{Zn}^{2+}]$ increases; in the cathode compartment $[\text{Zn}^{2+}]$ decreases **20.71** $E^\circ = 0.763 \text{ V}$, $\text{pH} = 1.6$ **20.73** (a) The emf of a battery decreases as it is used. The concentrations of products increase and the concentrations of reactants decrease, causing Q to increase and E_{cell} to decrease. (b) A D-size battery contains more reactants than a AA, enabling the D to provide power for a longer time.
20.75 (a) 464 g PbO_2 (b) $3.74 \times 10^5 \text{ C}$ of charge transferred
20.77 (a) The anode (b) $E^\circ = 0.50 \text{ V}$ (c) The emf of the battery, 3.5 V, is exactly the standard cell potential calculated in part (b). (d) At ambient conditions, $E \approx E^\circ$, so $\log Q \approx 1$. Assuming that the value of E° is relatively constant with temperature, the value of the second term in the Nernst equation is approximately zero at 37°C , and $E \approx 3.5 \text{ V}$.
20.79 (a) The cell emf will have a smaller value. (b) NiMH batteries use an alloy such as ZrNi_2 as the anode material. This eliminates the use and disposal problems associated with Cd , a toxic heavy metal.
20.81 The main advantage of a fuel cell is that fuel is continuously supplied, so that it can produce electrical current for a time limited only by the amount of available fuel. For the hydrogen-oxygen fuel cell, this is also a disadvantage because volatile and explosive hydrogen must be acquired and stored. Alkaline batteries are convenient, but they have a short lifetime, and the disposal of their zinc and manganese solids is more problematic than disposal of water produced by the hydrogen-oxygen fuel cell. **20.83** (a) anode: $\text{Fe}(s) \longrightarrow \text{Fe}^{2+}(aq) + 2e^-$; cathode: $\text{O}_2(g) + 4 \text{H}^+(aq) + 4e^- \longrightarrow 2 \text{H}_2\text{O}(l)$ (b) $2 \text{Fe}^{2+}(aq) + 3 \text{H}_2\text{O}(l) + 3 \text{H}_2\text{O}(l) \longrightarrow \text{Fe}_2\text{O}_3 \cdot 3 \text{H}_2\text{O}(s) + 6 \text{H}^+(aq) + 2e^-$; $\text{O}_2(g) + 4 \text{H}^+(aq) + 4e^- \longrightarrow 2 \text{H}_2\text{O}(l)$ **20.85** (a) Mg is called a "sacrificial anode" because it has a more negative E_{red}° than the pipe metal and is preferentially oxidized when the two are coupled. It is sacrificed to preserve the pipe. (b) E_{red}° for Mg^{2+} is -2.37 V , more negative than most metals present in pipes, including Fe and Zn . **20.87** Under acidic conditions, air (O_2) oxidation of $\text{Zn}(s)$, 1.99 V; $\text{Fe}(s)$, 1.67 V; and $\text{Cu}(s)$, 0.893 V are all spontaneous. When the three metals are in contact, Zn will act as a sacrificial anode for both Fe and Cu , but after the Zn is depleted, Fe will be oxidized (corroded). **20.89** (a) *Electrolysis* is an electrochemical process driven by an outside energy source. (b) By definition, electrolysis reactions are nonspontaneous. (c) $2 \text{Cl}^-(l) \longrightarrow \text{Cl}_2(g) + 2e^-$ (d) When an aqueous solution of NaCl undergoes electrolysis, sodium metal is not formed because H_2O is preferentially reduced to form $\text{H}_2(g)$.
20.91 (a) 236 g $\text{Cr}(s)$ (b) 2.51 A **20.93** (a) $4.0 \times 10^5 \text{ g Li}$ (b) The minimum voltage required to drive the electrolysis is +4.41 V.
20.95 Gold is less active than copper and thus more difficult to oxidize. When crude copper is refined by electrolysis, Cu is oxidized from the crude anode, but any metallic gold present in the crude copper is not oxidized, so it accumulates near the anode, available for collection.
20.97 (a) $2 \text{Ni}^+(aq) \longrightarrow \text{Ni}(s) + \text{Ni}^{2+}(aq)$ (b) $3 \text{MnO}_4^{2-}(aq) + 4 \text{H}^+(aq) \longrightarrow 2 \text{MnO}_4^-(aq) + \text{MnO}_2(s) + 2 \text{H}_2\text{O}(l)$

(c) $3\text{H}_2\text{SO}_3(aq) \longrightarrow \text{S}(s) + 2\text{HSO}_4^-(aq) + 2\text{H}^+(aq) + \text{H}_2\text{O}(l)$
 (d) $\text{Cl}_2(aq) + 2\text{OH}^-(aq) \longrightarrow \text{Cl}^-(aq) + \text{ClO}^-(aq) + \text{H}_2\text{O}(l)$
20.100 (a) $E^\circ = 0.627\text{V}$, spontaneous (b) $E^\circ = -0.82\text{V}$, nonspontaneous (c) $E^\circ = 0.93\text{V}$, spontaneous (d) $E^\circ = 0.183\text{V}$, spontaneous
20.104 $K = 1.6 \times 10^6$ **20.107** The ship's hull should be made negative. The ship, as a negatively charged "electrode," becomes the site of reduction, rather than oxidation, in an electrolytic process.
20.110 $3.0 \times 10^4\text{ kWh}$ required **20.112** (a) H_2 is being oxidized and N_2 is being reduced. (b) $K = 6.9 \times 10^5$ (c) $E^\circ = 0.05755\text{V}$
20.115 (a) $E^\circ = 0.028\text{V}$ (b) cathode: $\text{Ag}^+(aq) + e^- \longrightarrow \text{Ag}(s)$; anode: $\text{Fe}^{2+}(aq) \longrightarrow \text{Fe}^{3+}(aq) + e^-$ (c) $\Delta S^\circ = 148.5\text{J}$. Since ΔS° is positive, ΔG° will become more negative and E° will become more positive as temperature is increased. **20.118** K_{sp} for AgSCN is 1.0×10^{-12} .

CHAPTER 21

21.1 (a) ^{24}Ne ; outside; reduce neutron-to-proton ratio via β decay (b) ^{32}Cl ; outside; increase neutron-to-proton ratio via positron emission or orbital electron capture (c) ^{108}Sn ; outside; increase neutron-to-proton ratio via positron emission or orbital electron capture (d) ^{216}Po ; outside; nuclei with $Z \geq 84$ usually decay via α emission. **21.4** (a) 7 min (b) 0.1 min^{-1} (c) 30% (3/10) of the sample remains after 12 min. (d) $^{88}_{41}\text{Nb}$ **21.5** (a) $^{10}_5\text{B}$, $^{11}_5\text{B}$; $^{12}_6\text{C}$, $^{13}_6\text{C}$; $^{14}_7\text{N}$, $^{15}_7\text{N}$; $^{16}_8\text{O}$, $^{17}_8\text{O}$, $^{18}_8\text{O}$; $^{19}_9\text{F}$ (b) $^{14}_6\text{C}$ (c) $^{11}_6\text{C}$, $^{13}_7\text{N}$, $^{15}_8\text{O}$, $^{18}_9\text{F}$ (d) $^{11}_6\text{C}$ **21.7** (a) 25 protons, 30 neutrons (b) 80 protons, 121 neutrons (c) 19 protons, 20 neutrons
21.9 (a) ^1_0n (b) ^4_2He or α (c) $^0_0\gamma$ or γ **21.11** (a) $^{90}_{37}\text{Rb} \longrightarrow ^{90}_{38}\text{Sr} + ^0_{-1}\text{e}$ (b) $^{72}_{34}\text{Se} + ^0_{-1}\text{e}$ (orbital electron) $\longrightarrow ^{72}_{33}\text{As}$ (c) $^{76}_{36}\text{Kr} \longrightarrow ^{76}_{35}\text{Br} + ^0_{-1}\text{e}$ (d) $^{226}_{88}\text{Ra} \longrightarrow ^{222}_{86}\text{Rn} + ^4_2\text{He}$ **21.13** (a) $^{211}_{82}\text{Pb} \longrightarrow ^{211}_{83}\text{Bi} + ^0_{-1}\beta$ (b) $^{50}_{25}\text{Mn} \longrightarrow ^{50}_{24}\text{Cr} + ^0_{-1}\text{e}$ (c) $^{179}_{74}\text{W} + ^0_{-1}\text{e} \longrightarrow ^{179}_{73}\text{Ta}$ (d) $^{230}_{90}\text{Th} \longrightarrow ^{226}_{88}\text{Ra} + ^4_2\text{He}$ **21.15** 7 alpha emissions, 4 beta emissions **21.17** (a) Positron emission (for low atomic numbers, positron emission is more common than electron capture) (b) beta emission (c) beta emission (d) beta emission **21.19** (a) Stable: $^{39}_{19}\text{K}$, 20 neutrons is a magic number (b) stable: $^{83}_{33}\text{Bi}$, 126 neutrons is a magic number (c) stable: $^{58}_{28}\text{Ni}$ even proton, even neutron more likely to be stable; $^{65}_{28}\text{Ni}$ has high neutron-to-proton ratio **21.21** (a) ^4_2He (c) $^{40}_{20}\text{Ca}$ (e) $^{126}_{82}\text{Pb}$
21.23 The alpha particle, ^4_2He , has a magic number of both protons and neutrons, while the proton is an odd proton, even neutron particle. Alpha is a very stable emitted particle, which makes alpha emission a favorable process. The proton is not a stable emitted particle, and its formation does not encourage proton emission as a process.
21.25 Protons and alpha particles are positively charged and must be moving very fast to overcome electrostatic forces that would repel them from the target nucleus. Neutrons are electrically neutral and not repelled by the nucleus. **21.27** (a) $^{252}_{98}\text{Cf} + ^{10}_5\text{B} \longrightarrow 3^1_0\text{n} + ^{259}_{103}\text{Lr}$ (b) $^2_1\text{H} + ^4_2\text{He} \longrightarrow ^4_2\text{He} + ^1_1\text{H}$ (c) $^1_1\text{H} + ^{11}_5\text{B} \longrightarrow 3^4_2\text{He}$ (d) $^{122}_{53}\text{I} \longrightarrow ^{122}_{54}\text{Xe} + ^0_{-1}\text{e}$ (e) $^{59}_{26}\text{Fe} \longrightarrow ^0_{-1}\text{e} + ^{59}_{27}\text{Co}$
21.29 (a) $^{238}_{92}\text{U} + ^4_2\text{He} \longrightarrow ^{241}_{94}\text{Pu} + ^1_0\text{n}$ (b) $^{14}_7\text{N} + ^4_2\text{He} \longrightarrow ^{17}_8\text{O} + ^1_1\text{H}$ (c) $^{56}_{26}\text{Fe} + ^4_2\text{He} \longrightarrow ^{60}_{29}\text{Cu} + ^0_{-1}\text{e}$ **21.31** (a) True. The decay rate constant and half-life are inversely related. (b) False. If X is not radioactive, its half-life is essentially infinity. (c) True. Changes in the amount of A would be substantial and measurable over the 40-year time frame, while changes in the amount of X would be very small and difficult to detect. **21.33** When the watch is 50 years old, only 6% of the tritium remains. The dial will be dimmed by 94%. **21.35** The source must be replaced after 2.18 yr or 26.2 months; this corresponds to August 2012. **21.37** (a) 1.1×10^{11} alpha particles emitted in 5.0 min (b) 9.9 mCi **21.39** $k = 1.21 \times 10^{-4}\text{ yr}^{-1}$; $t = 4.3 \times 10^3\text{ yr}$ **21.41** $k = 5.46 \times 10^{-10}\text{ yr}^{-1}$; $t = 3.0 \times 10^9\text{ yr}$ **21.43** The energy released when one mole of Fe_2O_3 reacts is $8.515 \times 10^3\text{ J}$. The energy released when one mole of ^4_2He is formed from protons and neutrons is

$2.73 \times 10^{12}\text{ J}$. This is 3×10^8 or 300 million times as much energy as the thermite reaction. **21.45** $\Delta m = 0.2414960\text{ amu}$, $\Delta E = 3.604129 \times 10^{-11}\text{ J}/^{27}\text{Al}$ nucleus required, $8.044234 \times 10^{13}\text{ J}/100\text{ g }^{27}\text{Al}$ **21.47** (a) Nuclear mass: ^2H , 2.013553 amu; ^4He , 4.001505 amu; ^6Li , 6.0134771 amu (b) nuclear binding energy: ^2H , $3.564 \times 10^{-13}\text{ J}$; ^4He , $4.5336 \times 10^{-12}\text{ J}$; ^6Li , $5.12602 \times 10^{-12}\text{ J}$ (c) binding energy/nucleon: ^2H , $1.782 \times 10^{-13}\text{ J/nucleon}$; ^4He , $1.1334 \times 10^{-12}\text{ J/nucleon}$; ^6Li , $8.54337 \times 10^{-13}\text{ J/nucleon}$. This trend in binding energy/nucleon agrees with the curve in Figure 21.12. The anomalously high calculated value for ^4He is also apparent on the figure. **21.49** (a) $1.71 \times 10^5\text{ kg/d}$ (b) $2.1 \times 10^8\text{ g }^{235}\text{U}$ **21.51** (a) ^{59}Co ; it has the largest binding energy per nucleon, and binding energy gives rise to mass defect. **21.53** (a) NaI is a good source of iodine because iodine is a large percentage of its mass; it is completely dissociated into ions in aqueous solution, and iodine in the form of $\text{I}^-(aq)$ is mobile and immediately available for biouptake. (b) A Geiger counter placed near the thyroid immediately after ingestion will register background, then gradually increase in signal until the concentration of iodine in the thyroid reaches a maximum. Over time, iodine-131 decays, and the signal decreases. (c) The radioactive iodine will decay to 0.01% of the original amount in approximately 82 days. **21.55** ^{235}U **21.57** The control rods in a nuclear reactor regulate the flux of neutrons to keep the reaction chain self-sustaining and also prevent the reactor core from overheating. They are composed of materials such as boron or cadmium that absorb neutrons. **21.59** (a) $^1_1\text{H} + ^1_1\text{H} \longrightarrow ^3_2\text{He} + ^1_0\text{n}$ (b) $^{239}_{92}\text{U} + ^1_0\text{n} \longrightarrow ^{133}_{51}\text{Sb} + ^{98}_{41}\text{Nb} + 9^1_0\text{n}$ **21.61** (a) $\Delta m = 0.006627\text{ g/mol}$; $\Delta E = 5.956 \times 10^{11}\text{ J} = 5.956 \times 10^8\text{ kJ/mol } ^1_1\text{H}$ (b) The extremely high temperature is required to overcome electrostatic charge repulsions between the nuclei so that they can come together to react. **21.63** (a) Boiling water reactor (b) fast breeder reactor (c) gas-cooled reactor **21.65** Hydrogen abstraction: $\text{RCOOH} + \cdot\text{OH} \longrightarrow \text{RCOO}\cdot + \text{H}_2\text{O}$; deprotonation: $\text{RCOOH} + \text{OH}^- \longrightarrow \text{RCOO}^- + \text{H}_2\text{O}$. Hydroxyl radical is more toxic to living systems because it produces other radicals when it reacts with molecules in the organism. Hydroxide ion, OH^- , on the other hand, will be readily neutralized in the buffered cell environment. The acid-base reactions of OH^- are usually much less disruptive to the organism than the chain of redox reactions initiated by $\cdot\text{OH}$ radical. **21.67** (a) $5.3 \times 10^8\text{ dis/s}$, $5.3 \times 10^8\text{ Bq}$ (b) $6.1 \times 10^2\text{ mrad}$, $6.1 \times 10^{-3}\text{ Gy}$ (c) $5.8 \times 10^3\text{ mrem}$, $5.8 \times 10^{-2}\text{ Sv}$ **21.69** $^{210}_{82}\text{Pb}$ **21.71** (a) $^{36}_{17}\text{Cl} \longrightarrow ^{36}_{18}\text{Ar} + ^0_{-1}\text{e}$ (b) ^{35}Cl and ^{37}Cl both have an odd number of protons but an even number of neutrons. ^{36}Cl has an odd number of protons and neutrons, so it is less stable than the other two isotopes. **21.73** (a) $^6_3\text{Li} + ^{56}_{28}\text{Ni} \longrightarrow ^{62}_{31}\text{Ga}$ (b) $^{40}_{20}\text{Ca} + ^{248}_{96}\text{Cm} \longrightarrow ^{147}_{62}\text{Sm} + ^{141}_{54}\text{Xe}$ (c) $^{88}_{38}\text{Sr} + ^{84}_{36}\text{Kr} \longrightarrow ^{116}_{46}\text{Pd} + ^{56}_{28}\text{Ni}$ (d) $^{40}_{20}\text{Ca} + ^{238}_{92}\text{U} \longrightarrow ^{70}_{20}\text{Zn} + 4^1_0\text{n} + 2^{102}_{41}\text{Nb}$
21.77 The C—OH bond of the acid and the O—H bond of the alcohol break in this reaction. Initially, ^{18}O is present in the C— ^{18}OH group of the alcohol. In order for ^{18}O to end up in the ester, the ^{18}O —H bond of the alcohol must break. This requires that the C—OH bond in the acid also breaks. The unlabeled O from the acid ends up in the H_2O product. **21.79** ^7Be , $8.612 \times 10^{-13}\text{ J/nucleon}$; ^9Be , $1.035 \times 10^{-12}\text{ J/nucleon}$; ^{10}Be , $1.042 \times 10^{-12}\text{ J/nucleon}$. The binding energies/nucleon for ^9Be and ^{10}Be are very similar; that for ^{10}Be is slightly higher. **21.85** $1.4 \times 10^4\text{ kg C}_8\text{H}_{18}$

CHAPTER 22

22.1 (a) C_2H_4 , the structure on the left, is the stable compound. Carbon can form strong multiple bonds to satisfy the octet rule, while silicon cannot. (b) The geometry about the central atoms in C_2H_4 is trigonal planar. **22.3** Molecules (b) and (d) will have the seesaw structure shown in the figure. **22.6** (c) Density, the ratio of mass to volume, increases going down the family; only this trend is consistent with the data in the figure. Other properties do not match the trend because (a) electronegativity and (b) first ionization energy both decrease rather than increase going down the family. Trends for both (d) X—X single bond enthalpy and (e) electron affinity are

somewhat erratic, with the trends decreasing from S to Po, and anomalous values for the properties of O, probably owing to its small covalent radius. **22.9** The compound on the left, with the strained three-membered ring, will be the most generally reactive. The larger the deviation from ideal bond angles, the more strain in the molecule and the more generally reactive it is. **22.11** Metals: (b) Sr, (c) Mn, (e) Na; nonmetals: (a) P, (d) Se, (f) Kr; metalloids: none. **22.13** (a) O (b) Br (c) Ba (d) O (e) Co (f) Br **22.15** (a) N is too small a central atom to fit five fluorine atoms, and it does not have available *d* orbitals, which can help accommodate more than eight electrons. (b) Si does not readily form π bonds, which are necessary to satisfy the octet rule for both atoms in the molecule. (c) As has a lower electronegativity than N; that is, it more readily gives up electrons to an acceptor and is more easily oxidized. **22.17** (a) $\text{NaOCH}_3(s) + \text{H}_2\text{O}(l) \longrightarrow \text{NaOH}(aq) + \text{CH}_3\text{OH}(aq)$ (b) $\text{CuO}(s) + 2\text{HNO}_3(aq) \longrightarrow \text{Cu}(\text{NO}_3)_2(aq) + \text{H}_2\text{O}(l)$ (c) $\text{WO}_3(s) + 3\text{H}_2(g) \longrightarrow \text{W}(s) + 3\text{H}_2\text{O}(g)$ (d) $4\text{NH}_2\text{OH}(l) + \text{O}_2(g) \longrightarrow 6\text{H}_2\text{O}(l) + 2\text{N}_2(g)$ (e) $\text{Al}_4\text{C}_3(s) + 12\text{H}_2\text{O}(l) \longrightarrow 4\text{Al}(\text{OH})_3(s) + 3\text{CH}_4(g)$ **22.19** (a) ^1H , protium; ^2H , deuterium; ^3H , tritium (b) in order of decreasing natural abundance: protium > deuterium > tritium (c) Tritium is radioactive. (d) $^3\text{H} \longrightarrow ^3\text{He} + {}_{-1}^0\text{e}$ **22.21** Like other elements in group 1A, hydrogen has only one valence electron and its most common oxidation number is +1.

(e) $\text{PbO}(s) + \text{H}_2(g) \xrightarrow{\Delta} \text{Pb}(s) + \text{H}_2\text{O}(g)$ **22.27** (a) Ionic (b) molecular (c) metallic **22.29** Vehicle fuels produce energy via combustion reactions. The combustion of hydrogen is very exothermic and its only product, H_2O , is a nonpollutant. **22.31** Xenon has a lower ionization energy than argon; because the valence electrons are not as strongly attracted to the nucleus, they are more readily promoted to a state in which the atom can form bonds with fluorine. Also, Xe is larger and can more easily accommodate an expanded octet of electrons.

22.33 (a) $\text{Ca}(\text{OBr})_2$, Br, +1 (b) HBrO_3 , Br, +5 (c) XeO_3 , Xe, +6 (d) ClO_4^- , Cl, +7 (e) HIO_2 , I, +3 (f) IF_5 , I, +5; F, -1 **22.35** (a) iron(III) chloride, Cl, +5 (b) chlorous acid, Cl, +3 (c) xenon hexafluoride, F, -1 (d) bromine pentafluoride; Br, +5; F, -1 (e) xenon oxide tetrafluoride, F, -1 (f) iodic acid, I, +5 **22.37** (a) van der Waals intermolecular attractive forces increase with increasing number of electrons in the atoms. (b) F_2 reacts with water: $\text{F}_2(g) + \text{H}_2\text{O}(l) \longrightarrow 2\text{HF}(g) + \text{O}_2(g)$. That is, fluorine is too strong an oxidizing agent to exist in water. (c) HF has extensive hydrogen bonding. (d) Oxidizing power is related to electronegativity. Electronegativity and oxidizing power decrease in the order given. **22.39**(a) $2\text{HgO}(s) \xrightarrow{\Delta} 2\text{Hg}(l) + \text{O}_2(g)$

(f) $3\text{O}_2(g) \xrightarrow{h\nu} 2\text{O}_3(g)$ **22.41** (a) acidic (b) acidic (c) amphoteric (d) basic **22.43** (a) H_2SeO_3 , Se, +4 (b) KHSO_3 , S, +4 (c) H_2Te , Te, -2 (d) CS_2 , S, -2 (e) CaSO_4 , S, +6 (f) CdS , S, -2 (g) ZnTe , Te, -2

22.47

Trigonal pyramidal

Bent (free rotation around S-S bond)

Tetrahedral (around S)

The molecule is bent around the central oxygen and nitrogen atoms; the four atoms need not be coplanar. The right-most form does not minimize formal charges and is less important in the actual bonding model. The oxidation state of N is +3.

(b)

The molecule is linear. The oxidation state of N is -1/3.

(c)

The geometry is tetrahedral around the left nitrogen, trigonal pyramidal around the right. The oxidation state of N is -2.

(d)

The ion is trigonal planar; it has three equivalent resonance forms. The oxidation state of N is +5.

(e) P_2O_5 , +5 (f) Na_3PO_4 , +5 **22.61** (a) Phosphorus is a larger atom than nitrogen, and P has energetically available *3d* orbitals, which participate in the bonding, but nitrogen does not. (b) Only one of the three hydrogens in H_3PO_2 is bonded to oxygen. The other two are bonded directly to phosphorus and are not easily ionized. (c) PH_3 is a weaker base

than H_2O so any attempt to add H^+ to PH_3 in the presence of H_2O causes protonation of H_2O . (d) The P_4 molecules in white phosphorus have more severely strained bond angles than the chains in red phosphorus, causing white phosphorus to be more reactive.

22.69

22.75 (a) Tetrahedral (b) Metasilicic acid will probably adopt the single-strand silicate chain structure shown in Figure 22.34 (b). The Si to O ratio is correct and there are two terminal O atoms per Si that can accommodate the two H atoms associated with each Si atom of the acid.

22.77 (a) Diborane has bridging H atoms linking the two B atoms. The structure of ethane has the C atoms bound directly, with no bridging atoms. (b) B_2H_6 is an electron-deficient molecule. The 6 valence electron pairs are all involved in B—H sigma bonding, so the only way to satisfy the octet rule at B is to have the bridging H atoms shown in Figure 22.36. (c) The term *hydridic* indicates that the H atoms in B_2H_6 have more than the usual amount of electron density for a covalently bound H atom.

The formal charge on N is +1 and on each O atom is -1. The four electronegative oxygen atoms withdraw electron density, leaving the nitrogen deficient. Since N can form a maximum of four bonds, it cannot form a π bond with one or more of the O atoms to regain electron density, as the P atom in PO_4^{3-} does. Also, the short N—O distance would lead to a tight tetrahedron of O atoms subject to steric repulsion.

$9.7 \times 10^4 \text{ L H}_2\text{S}$ (c) $1.9 \times 10^5 \text{ g S}$ produced **22.97** The average bond enthalpies are H—O, 463 kJ; H—S, 367 kJ; H—Se, 316 kJ; H—Te, 266 kJ. The H—X bond enthalpy decreases steadily in the series. The origin of this effect is probably the increasing size of the orbital from X with which the hydrogen 1s orbital must overlap.

22.101 Dimethylhydrazine produces 0.0369 mol gas per gram of reactants, while methylhydrazine produces 0.0388 mol gas per gram of reactants. Methylhydrazine has marginally greater thrust.

(b)

CHAPTER 23

(b) Coordination number = 4, coordination geometry = square planar

(c) oxidation state = +2 **23.4** aminotrichloroplatinate(II)

23.6 Molecules (1), (3), and (4) are chiral because their mirror images are not superimposable on the original molecules. **23.8** (a) diagram (4)

(b) diagram (1) (c) diagram (3) (d) diagram (2) **23.11** The lanthanide contraction is the name given to the decrease in atomic size due to the build-up in effective nuclear charge as we move through the lanthanides (elements 58–71) and beyond them. This effect offsets the expected increase in atomic size, decrease in ionization energy, and increase in electron affinity going from period 5 to period 6 transition elements. This causes the chemical properties of period 5 and period 6 elements in the same family to be even more similar than we would expect.

23.13 (a) All transition metal atoms have two s-electrons in their valence shell. Loss of these s-electrons leads to the +2 oxidation state common for most of the transition metals. **23.15** (a) Ti^{3+} , $[\text{Ar}]3d^1$ (b) Ru^{2+} , $[\text{Kr}]4d^6$ (c) Au^{3+} , $[\text{Xe}]4f^{14}5d^8$ (d) Mn^{4+} , $[\text{Ar}]3d^3$

23.17 (a) The unpaired electrons in a paramagnetic material cause it to be weakly attracted into a magnetic field. A diamagnetic material, where all electrons are paired, is very weakly repelled by a magnetic field. **23.19** The diagram shows a material with misaligned spins that become aligned in the direction of an applied magnetic field. This is a paramagnetic material. **23.21** (a) In Werner's theory, *primary valence* is the charge of the metal cation at the center of the complex. *Secondary valence* is the number of atoms bound or coordinated to the central metal ion. The modern terms for these concepts are *oxidation state* and *coordination number*, respectively. (b) Ligands are the Lewis base in metal–ligand interactions. As such, they must possess at least one unshared electron pair. NH_3 has an unshared electron pair but BH_3 , with less than 8 electrons about B, has no unshared electron pair and cannot act as a ligand. **23.23** (a) +2 (b) 6 (c) 2 mol $\text{AgBr}(\text{s})$ will precipitate per mole of complex. **23.25** (a) Coordination number = 4, oxidation number = +2; 4 Cl^- (b) 5, +4; 4 Cl^- , 1 O^{2-} (c) 6, +3; 4 N, 2 Cl^- (d) 5, +2; 5 C (e) 6, +3; 6 O (f) 4, +2; 4 N **23.27** (a) A monodentate ligand binds to a metal via one atom, a bidentate ligand binds through two atoms. (b) Three bidentate ligands fill the coordination sphere of a six-coordinate complex. (c) A tridentate ligand has at least three atoms with unshared electron pairs in the correct orientation to simultaneously bind one or more metal ions. **23.29** (a) *Ortho*-phenanthroline, *o*-phen, is bidentate (b) oxalate, $\text{C}_2\text{O}_4^{2-}$, is bidentate (c) ethylenediaminetetraacetate, EDTA, is pentadentate (d) ethylenediamine, en, is bidentate. **23.31** (a) The term *chelate effect* refers to the special stability associated with formation of a metal complex containing a polydentate (chelate) ligand relative to a complex containing only monodentate ligands. (b) The increase in entropy, $+\Delta\text{S}$, associated with the substitution of a chelating ligand for two or more monodentate ligands generally gives rise to the *chelate effect*. Chemical reactions with $+\Delta\text{S}$ tend to be spontaneous, have negative ΔG and large values of K . (c) Polydentate ligands are used as *sequestering agents* to bind metal ions and prevent them from under-

going unwanted chemical reactions without removing them from solution. **23.33** The ligand is not typically a chelate. The entire molecule is planar and the benzene rings on either side of the two N atoms inhibit their approach in the correct orientation for chelation. **23.35** (a) $[\text{Cr}(\text{NH}_3)_6](\text{NO}_3)_3$ (b) $[\text{Co}(\text{NH}_3)_4\text{CO}_3]_2\text{SO}_4$ (c) $[\text{Pt}(\text{en})_2\text{Cl}_2]\text{Br}_2$ (d) $[\text{K}[\text{V}(\text{H}_2\text{O})_2\text{Br}_4]]$ (e) $[\text{Zn}(\text{en})_2][\text{HgI}_4]$ **23.37** (a) tetraamminedichlororhodium(III) chloride (b) potassium hexachlorotitanate(IV) (c) tetrachlorooxomolybdenum(VI) (d) tetraaqua(oxalato)platinum(IV) bromide

23.39

(b) $[\text{Pd}(\text{NH}_3)_2(\text{ONO})_2]$, $[\text{Pd}(\text{NH}_3)_2(\text{NO}_2)_2]$

(d) $[\text{Co}(\text{NH}_3)_4\text{Br}_2]\text{Cl}$, $[\text{Co}(\text{NH}_3)_4\text{BrCl}]\text{Br}$ **23.41** Yes. No structural or stereoisomers are possible for a tetrahedral complex of the form MA_2B_2 . The complex must be square planar with cis and trans geometric isomers. **23.43** (a) One isomer (b) trans and cis isomers with 180° and 90° $\text{Cl}-\text{Ir}-\text{Cl}$ angles, respectively (c) trans and cis isomers with 180° and 90° $\text{Cl}-\text{Fe}-\text{Cl}$ angles, respectively. The cis isomer is optically active. **23.45** (a) We cannot see the light with 300 nm wavelength, but we can see the 500 nm light. (b) Complementary colors are opposite each other on an artist's color wheel. (c) A colored metal complex absorbs visible light of its complementary color. (d) 196 kJ/mol **23.47** No. All 6 d -electrons in a low-spin octahedral $\text{Fe}(\text{II})$ complex will pair and occupy the low-energy d_{xy} , d_{xz} , and d_{yz} orbitals. With no unpaired electrons, the complex cannot be paramagnetic. **23.49** Most of the attraction between a metal ion and a ligand is electrostatic. Whether the interaction is ion-ion or ion-dipole, the ligand is strongly attracted to the metal center and can be modeled as a point negative charge.

(b) The magnitude of Δ and the energy of the $d-d$ transition for a d^1 complex are equal. (c) $\Delta = 220 \text{ kJ/mol}$ **23.53** A yellow color is due to absorption of light around 400 to 430 nm, a blue color to absorption near 620 nm. The shorter wavelength corresponds to a higher-energy electron transition and larger Δ value. Cyanide is a stronger-field ligand, and its complexes are expected to have larger Δ values than aqua complexes. **23.55** (a) Ti^{3+} , d^1 (b) Co^{3+} , d^6 (c) Ru^{3+} , d^5 (d) Mo^{5+} , d^1 , (e) Re^{3+} , d^4 **23.57** Yes. A weak-field ligand leads to a small Δ value and a small d -orbital splitting energy. If the splitting energy of a complex is smaller than the energy required to pair electrons in an orbital, the complex is high spin. **23.59** (a) Mn, $[\text{Ar}]4s^23d^5$; Mn^{2+} , $[\text{Ar}]3d^5$; 1 unpaired electron (b) Ru, $[\text{Kr}]5s^14d^7$; Ru^{2+} , $[\text{Kr}]4d^6$; 0 unpaired electrons (c) Rh, $[\text{Kr}]5s^14d^8$; Rh^{2+} , $[\text{Kr}]4d^7$; 1 unpaired electron **23.61** All complexes in this exercise are six-coordinate octahedral.

23.63

23.67 $[\text{Pt}(\text{NH}_3)_6]\text{Cl}_4$; $[\text{Pt}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}_2$; $[\text{Pt}(\text{NH}_3)_3\text{Cl}_3]\text{Cl}$; $[\text{Pt}(\text{NH}_3)_2\text{Cl}_4]$; $\text{K}[\text{Pt}(\text{NH}_3)\text{Cl}_5]$

23.71 (a)

Both dmpe and en are bidentate ligands, binding through P and N, respectively. Because phosphorus is less electronegative than N, dmpe is a stronger electron pair donor and Lewis base than en. Dmpe creates a stronger ligand field and is higher on the spectrochemical series. Structurally, dmpe occupies a larger volume than en. M-P bonds are longer than M-N bonds and the two $-\text{CH}_3$ groups on each P atom in dmpe create more steric hindrance than the H atoms on N in en. (b) The oxidation state of Mo is zero. (c) The symbol $\overline{\text{P}}\overline{\text{P}}$ represents the bidentate dmpe ligand.

23.74 (a) Hemoglobin is the iron-containing protein that transports O_2 in human blood. (b) Chlorophylls are magnesium-containing porphyrins in plants. They are the key components in the conversion of solar energy into chemical energy that can be used by living organisms. (c) Siderophores are iron-binding compounds or ligands produced by a microorganism. They compete on a molecular level for iron in the medium outside the organism and carry needed iron into the cells of the organism. **23.76** (a) Pentacarbonyliron(0) (b) The oxidation state of iron must be zero. (c) Two. One isomer has CN in an axial position and the other has it in an equatorial position.

23.78 (a)

(b) Visible light with $\lambda = hc/\Delta$ is absorbed by the complex, promoting one of the d electrons into a higher-energy d -orbital. The remaining wavelengths are reflected or transmitted; the combination of these wavelengths is the color we see. (c) $[\text{V}(\text{H}_2\text{O})_6]^{3+}$ will absorb light with

higher energy because it has a larger Δ than $[\text{VF}_6]^{3-}$. H_2O is in the middle of the spectrochemical series and causes a larger Δ than F^- , a weak-field ligand. **23.80** $[\text{Co}(\text{NH}_3)_6]^{3+}$, yellow; $[\text{Co}(\text{H}_2\text{O})_6]^{2+}$, pink; $[\text{CoCl}_4]^{2-}$, blue

23.85

(b) sodium dicarbonyltetracyanoferrate(II) (c) +2, 6 *d*-electrons (d) We expect the complex to be low spin. Cyanide (and carbonyl) are high on the spectrochemical series, which means the complex will have a large Δ splitting, characteristic of low-spin complexes. **23.91** (a) Yes, the oxidation state of Co is +3 in both complexes. (b) Compound A has SO_4^{2-} outside the coordination sphere and coordinated Br^- , so it forms a precipitate with $\text{BaCl}_2(aq)$ but not $\text{AgNO}_3(aq)$. Compound B has Br^- outside the coordination sphere and coordinated SO_4^{2-} , so it forms a precipitate with $\text{AgNO}_3(aq)$ but not $\text{BaCl}_2(aq)$. (c) Compounds A and B are coordination sphere isomers. (d) Both compounds are strong electrolytes. **23.94** The chemical formula is $[\text{Pd}(\text{NC}_5\text{H}_5)_2\text{Br}_2]$. This is an electrically neutral square-planar complex of Pd(II), a nonelectrolyte whose solutions do not conduct electricity. Because the dipole moment is zero, it must be the trans isomer. **23.96** 47.3 mg Mg^{2+}/L , 53.4 mg Ca^{2+}/L **23.99** $\Delta E = 3.02 \times 10^{-19}$ J/photon, $\lambda = 657$ nm. The complex will absorb in the visible around 660 nm and appear blue-green.

CHAPTER 24

24.1 Molecules (c) and (d) are the same molecule. **24.4** Compound (b), which has hydrogen bonding, has the highest boiling point. **24.7** (a) sp^3 (b) sp^2 (c) sp^2 (d) sp **24.9** Numbering from the right on the condensed structural formula, C1 has trigonal-planar electron-domain geometry, 120° bond angles, and sp^2 hybridization; C2 and C5 have tetrahedral electron-domain geometry, 109° bond angles, and sp^3 hybridization; C3 and C4 have linear electron-domain geometry, 180° bond angles, and sp hybridization. **24.11** NH_3 and CO are not typical organic molecules. NH_3 contains no carbon atoms. Carbon monoxide contains a C atom that does not form four bonds. **24.13** (a) A straight-chain alkane has all carbon atoms connected in a continuous chain. A carbon atom is bound to no more than two other carbon atoms and forms only σ bonds. A branched-chain hydrocarbon has a branch; at least one carbon atom is bound to three or more carbon atoms. (b) An alkane is a complete molecule composed of carbon and hydrogen in which all bonds are σ bonds. An alkyl group is a substituent formed by removing a hydrogen atom from an alkane. **24.15** (a) 2-methylhexane (b) 4-ethyl-2,4-dimethyldecane

(c) $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}(\text{CH}_3)_2$

(d) $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}(\text{CH}_2\text{CH}_3)\text{CH}(\text{CH}_3)\text{CH}(\text{CH}_3)_2$

24.17 (a) 2,3-dimethylheptane (b) $\text{CH}_3\text{CH}_2\text{CH}_2\text{C}(\text{CH}_3)_3$

(d) 2,2,5-trimethylhexane (e) methylcyclobutane **24.19** 65

24.21 (a) Alkanes are said to be saturated because they cannot undergo addition reactions, such as those characteristic of carbon-carbon double bonds. (b) No. The compound C_4H_6 does not contain the maximum possible number of hydrogen atoms and is unsaturated.

24.23 (a) C_5H_{12} (b) C_5H_{10} (c) C_5H_{10} (d) C_5H_8 ; saturated: (a), (b); unsaturated: (c), (d) **24.25** One possible structure is

24.27 There are at least 46 structural isomers with the formula C_6H_{10} . A few of them are

(c) *cis*-6-methyl-3-octene (d) *para*-dibromobenzene (e) 4,4-dimethyl-1-hexyne **24.31** Geometric isomerism in alkenes is the result of restricted rotation about the double bond. In alkanes bonding sites are interchangeable by free rotation about the C—C single bonds. In alkynes there is only one additional bonding site on a triply bound carbon, so no isomerism results.

24.33 (a) No

(c) no (d) no **24.35** (a) An addition reaction is the addition of some reagent to the two atoms that form a multiple bond. In a substitution reaction one atom or group of atoms replaces another atom. Alkenes typically undergo addition, while aromatic hydrocarbons usually undergo substitution.

(b)

(c)

24.37 (a) The 60° C—C—C angles in the cyclopropane ring cause strain that provides a driving force for reactions that result in ring opening. There is no comparable strain in the five- or six-membered rings. (b) $\text{C}_2\text{H}_4(\text{g}) + \text{HBr}(\text{g}) \longrightarrow \text{CH}_3\text{CH}_2\text{Br}(\text{l})$;

24.39 Not necessarily. That the two rate laws are first order in both reactants and second order overall indicates that the activated complex in the rate-determining step in each mechanism is bimolecular and contains one molecule of each reactant. This is usually an indication that the mechanisms are the same, but it does not rule out the possibility of different fast steps or a different order of elementary steps.

24.41 $\Delta H_{\text{comb}}/\text{mol CH}_2$ for cyclopropane = 696.3 kJ, for cyclopentane = 663.4 kJ. $\Delta H_{\text{comb}}/\text{CH}_2$ group for cyclopropane is greater because C_3H_6 contains a strained ring. When combustion occurs, the strain is relieved and the stored energy is released. **24.43** (a) Alcohol (b) amine, alkene (c) ether (d) ketone, alkene (e) aldehyde (f) carboxylic acid, alkyne **24.45** (a) Propionaldehyde (or propanal):

(b) ethylmethyl ether:

**24.47** (a)

(b)

(c)

**24.49****24.51**

24.53 The presence of both —OH and —C=O groups in pure acetic acid leads us to conclude that it will be a strongly hydrogen-bonded substance. That the melting and boiling points of pure acetic acid are both higher than those of water, a substance we know to be strongly hydrogen-bonded, supports this conclusion.

24.55 (a) $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}(\text{OH})\text{CH}_3$ (b) $\text{CH}_3\text{CH}(\text{OH})\text{CH}_2\text{OH}$ 

(d)

(e) $\text{CH}_3\text{OCH}_2\text{CH}_3$ **24.57**

24.59 (a) An α -amino acid contains an NH_2 group attached to the carbon adjacent to the carboxylic acid function. (b) In protein formation, amino acids undergo a condensation reaction between the amino group of one molecule and the carboxylic acid group of another to form the amide linkage. (c) The bond that links amino acids in proteins is called the peptide bond.

24.61

24.63 (a)

(b) Three tripeptides are possible: Gly-Gly-His, GGH; Gly-His-Gly, GHG; His-Gly-Gly, HGG. **24.65** The primary structure of a protein refers to the sequence of amino acids in the chain. The secondary structure is the configuration (helical, folded, open) of the protein chain. The tertiary structure is the overall shape of the protein determined by the way the segments fold together. (b) X-ray crystallography is the primary and preferred technique for determining protein structure. **24.67** (a) Carbohydrates, or sugars, are polyhydroxyaldehydes or ketones composed of carbon, hydrogen, and oxygen. They are derived primarily from plants and are a major food source for animals. (b) A monosaccharide is a simple sugar molecule that cannot be decomposed into smaller sugar molecules by hydrolysis. (c) A disaccharide is a carbohydrate composed of two simple sugar units. Hydrolysis breaks a disaccharide into two monosaccharides. (d) A polysaccharide is a polymer composed of many simple sugar units. **24.69** The empirical formula of cellulose is $C_6H_{10}O_5$. As in glycogen, the six-membered ring form of glucose forms the monomer unit that is the basis of the polymer cellulose. In cellulose, glucose monomer units are joined by β linkages. **24.71** (a) In the linear form of mannose, the aldehydic carbon is C1. Carbon atoms 2, 3, 4, and 5 are chiral because they each carry four different groups. (b) Both the α (left) and β (right) forms are possible.

24.73 Two important kinds of lipids are fats and fatty acids. Structurally, fatty acids are carboxylic acids with a hydrocarbon chain of more than four carbon atoms (typically 16–20 carbon atoms). Fats are esters formed by condensation of an alcohol, often glycerol, and a fatty acid. Phospholipids are glycerol esters formed from one phosphoric acid $[RPO(OH)_2]$ and two fatty acid $(RCOOH)$ molecules. At body pH, the phosphate group is deprotonated and has a negative charge. The long, nonpolar hydrocarbon chains do not readily mix with water, but they do interact with the nonpolar chains of other phospholipid molecules to form the inside of a bilayer. The charged phosphate heads interact with polar water molecules on the outsides of the bilayer. **24.75** Purines, with the larger electron cloud and molar mass, will have larger dispersion forces than pyrimidines in aqueous solution. **24.77** 5'-TACG-3' **24.79** The complementary strand for 5'-GCATTGGC-3' is 3'-CGTAACCG-5'.

24.81

24.83

Cyclopentene does not show cis-trans isomerism because the existence of the ring demands that the C—C bonds be cis to one another. **24.86** (a) Aldehyde, trans-alkene, cis-alkene (b) ether, alcohol, alkene, amine (two of these, one aliphatic and one aromatic) (c) ketone (two of these), amine (two of these) (d) amide, alcohol (aromatic) **24.88** In a carboxylic acid, the electronegative carbonyl oxygen withdraws electron density from the O—H bond, rendering the bond more polar and the H more ionizable. And carboxylate anion is stabilized by resonance and encourages ionization of the carboxylic acid. In an alcohol no electronegative atoms are bound to the carbon that holds the —OH group, and the H is tightly bound to the O. **24.92** Glu-Cys-Gly is the only possible order. Glutamic acid has two carboxyl groups that can form a peptide bond with cysteine, so there are two possible structures for glutathione. **24.95** In both cases, stronger intermolecular forces lead to the higher boiling point. Ethanol contains O—H bonds, which form strong intermolecular hydrogen bonds, while dimethyl ether experiences only weak dipole-dipole and dispersion forces. The heavier and polar CH_2F_2 experiences dipole-dipole and stronger dispersion forces, while CH_4 experiences only weaker dispersion forces.

24.97

24.99 $\Delta G^\circ = 13 \text{ kJ}$ 

ANSWERS TO GIVE IT SOME THOUGHT

CHAPTER 1

page 5 (a) 100 (b) atoms

page 10 Water is composed of two types of atoms: hydrogen and oxygen. Hydrogen is composed only of hydrogen atoms, and oxygen is composed only of oxygen atoms. Therefore, hydrogen and oxygen are elements and water is a compound.

page 13 (a) Chemical change: Carbon dioxide and water are different compounds than sugar. (b) Physical change: Water in the gas phase becomes water in the solid phase (frost). (c) Physical change: Gold in the solid state becomes liquid and then resolidifies.

page 16 pg, picogram (10^{-12} g)

page 19 $2.5 \times 10^2 \text{ m}^3$ is, because it has units of length to the third power.

page 21 (b) Mass of a penny

page 27 Use all digits given in the conversion factor. Conversion factors may be exact and then have “infinite” significant digits (for example, $2.54 \text{ cm} = 1 \text{ inch}$ exactly). Usually, your answer will have its number of significant digits limited by those of the quantities given in the problem.

CHAPTER 2

page 41 (a) The law of multiple proportions. (b) The second compound must contain two oxygen atoms for each carbon atom (that is, twice as many carbon atoms as the first compound).

page 44 Most α particles pass through the foil without being deflected because most of the volume of the atoms that comprise the foil is empty space.

page 45 (a) The atom has 15 electrons because atoms have equal numbers of electrons and protons. (b) The protons reside in the nucleus of the atom.

page 48 Any single atom of chromium must be one of the isotopes of that element. The isotope mentioned has a mass of 52.94 amu and is probably ^{53}Cr . The atomic weight differs from the mass of any particular atom because it is the average atomic mass of the naturally occurring isotopes of the element.

page 51 (a) Cl, (b) third period and group 7A, (c) 17, (d) nonmetal

page 54 (a) C_2H_6 , (b) CH_3 , (c) Probably the ball-and-stick model because the angles between the sticks indicate the angles between the atoms

page 57 We write the empirical formulas for ionic compounds. Thus, the formula is CaO .

page 60 (a) The transition metals can form more than one type of cation, and the charges of these ions are therefore indicated explicitly with Roman numerals: Chromium(II) ion is Cr^{2+} . Calcium, on the other hand, always forms the Ca^{2+} ion, so there is no need to distinguish it from other calcium ions with different charges. (b) The *-ium* ending indicates that the ion is formed from nonmetals.

page 61 An *-ide* ending usually means a monatomic anion, although there are some anions with two atoms that are also named this way. An *-ate* ending indicates an oxyanion. The most common oxyanions have the *-ate* ending. An *-ite* ending also indicates an oxyanion, but one having less O than the anion whose name ends in *-ate*.

page 62 BO_3^{3-} and SiO_4^{4-} . The borate has three O atoms, like the other oxyanions of the second period in Figure 2.27, and its charge is $3-$, following the trend of increasing negative charge as you move to the left in the period. The silicate has four O atoms, as do the other oxyanions in the third period in Figure 2.25, and its charge is $4-$, also following the trend of increasing charge moving to the left.

page 65 Iodic acid, by analogy to the relationship between the chlorate ion and chloric acid

page 67

CHAPTER 3

page 78 Each $\text{Mg}(\text{OH})_2$ has 1 Mg, 2 O, and 2 H; thus, $3 \text{ Mg}(\text{OH})_2$ represents 3 Mg, 6 O, and 6 H.

page 83 The product is an ionic compound involving Na^+ and S^{2-} , and its chemical formula is therefore Na_2S .

page 88 (a) A mole of glucose. By inspecting their chemical formulas we find that glucose has more atoms of H and O than water and in addition it also has C atoms. Thus, a molecule of glucose has a greater mass than a molecule of water. (b) They both contain the same number of molecules because a mole of each substance contains 6.02×10^{23} molecules.

page 93 The N:H ratio is $2:4 = 1:2$.

page 96 There are experimental uncertainties in the measurements.

page 97 3.14 mol because $2 \text{ mol H}_2 \approx 1 \text{ mol O}_2$ based on the coefficients in the balanced equation

page 98 The number of grams of product formed is the sum of the masses of the two reactants, 50 g. When two substances react in a combination reaction, only one substance is formed as a product. According to the law of conservation of mass, the mass of the product must equal the masses of the two reactants.

CHAPTER 4

page 118 (a) $\text{K}^+(\text{aq})$ and $\text{CN}^-(\text{aq})$, (b) $\text{Na}^+(\text{aq})$ and $\text{ClO}_4^-(\text{aq})$

page 119 NaOH because it is the only solute that is a strong electrolyte

page 123 $\text{Na}^+(\text{aq})$ and $\text{NO}_3^-(\text{aq})$

page 125 Three. Each COOH group will partially ionize in water to form $\text{H}^+(\text{aq})$.

page 126 Only soluble metal hydroxides are classified as strong bases and $\text{Al}(\text{OH})_3$ is insoluble.

page 130 $\text{SO}_2(\text{g})$

page 133 (a) -3 , (b) $+5$

page 136 (a) Yes, nickel is below zinc in the activity series so $\text{Ni}^{2+}(\text{aq})$ will oxidize $\text{Zn}(\text{s})$ to form $\text{Ni}(\text{s})$ and $\text{Zn}^{2+}(\text{aq})$. (b) No reaction will occur because the $\text{Zn}^{2+}(\text{aq})$ ions cannot be further oxidized.

page 139 The second solution is more concentrated, 2.50 M, than the first solution, which has a concentration of 1.00 M.

page 142 The concentration is halved to 0.25 M.

CHAPTER 5

page 162 No. The potential energy is lower at the bottom of the hill. (b) Once the bike comes to a stop, its kinetic energy is zero, just as it was at the top of the hill.

page 163 Open system. Humans exchange matter and energy with their surroundings.

page 167 Endothermic

page 169 The balance (current state) does not depend on the ways the money may have been transferred into the account or on the particular expenditures made in withdrawing money from the account. It depends only on the net total of all the transactions.

page 169 Because E , P , and V are state functions that don't depend on path, $H = E + PV$ must also be a state function.

page 170 No. If ΔV is zero, then the expression $w = -P\Delta V$ is also zero.

page 171 A thermometer to measure temperature changes

page 173 No. Because only half as much matter is involved, the value of ΔH would be $\frac{1}{2}(-483.6 \text{ kJ}) = -241.8 \text{ kJ}$.

page 176 $\text{Hg}(l)$. Rearranging Equation 5.22 gives $\Delta T = \frac{q}{C_s \times m}$.

When q and m are constant for a series of substances, then $\Delta T = \frac{\text{constant}}{C_s}$. Therefore, the element with the smallest C_s in

Table 5.2 has the largest ΔT , $\text{Hg}(l)$.

page 181 (a) The sign of ΔH changes. (b) The magnitude of ΔH doubles.

page 184 No. Because $\text{O}_3(g)$ is not the most stable form of oxygen at 25°C , 1 atm [$\text{O}_2(g)$ is], ΔH_f° for $\text{O}_3(g)$ is not necessarily zero. In Appendix C we see that it is 142.3 kJ/mol .

page 189 Fats, because they have the largest fuel value of the three

page 191 Combustion of $\text{H}_2(g)$ produces only $\text{H}_2\text{O}(g)$. No $\text{CO}_2(g)$ or other gases that might contribute to climate change issues are produced.

CHAPTER 6

page 210 No. Both visible light and X-rays are forms of electromagnetic radiation. They therefore both travel at the speed of light, c . Their differing ability to penetrate skin is due to their different energies, which we will discuss in the next section.

page 211 $E = hv = (6.63 \times 10^{-34} \text{ J}\cdot\text{s})(5 \times 10^{-14} \text{ s}^{-1}) = 3 \times 10^{-30} \text{ J}$; this radiation cannot produce a burst of $5 \times 10^{-36} \text{ J}$ because it can only produce energy in multiples of $3 \times 10^{-30} \text{ J}$.

page 212 Ultraviolet. Figure 6.4 shows that a photon in the ultraviolet region of the electromagnetic spectrum has a higher frequency and therefore a greater energy than a photon in the infrared region.

page 214 According to the third postulate, photons of only certain allowed frequencies can be absorbed or emitted as the electron changes energy state. The lines in the spectrum correspond to the allowed frequencies.

page 215 Absorb, because it is moving from a lower-energy state ($n = 3$) to a higher-energy state ($n = 7$)

page 217 Yes, all moving objects produce matter waves, but the wavelengths associated with macroscopic objects, such as the baseball, are too small to allow for any way of observing them.

page 219 The small size and mass of subatomic particles. The term $h/4\pi$ in the uncertainty principle is a very small number that becomes important only when considering extremely small objects, such as electrons.

page 220 Bohr proposed that the electron in the hydrogen atom moves in a well-defined circular path around the nucleus (an orbit). In the quantum-mechanical model, no effort is made to describe the motion of the electron. An orbital is a wave function related to the probability of finding the electron at any point in space.

page 221 The energy of an electron in the hydrogen atom is proportional to $-1/n^2$, as seen in Equation 6.5. The difference between $-1/(2)^2$ and $-1/(1)^2$ is much greater than the difference between $-1/(3)^2$ and $-1/(2)^2$.

page 226 (a) There is one $3s$ orbital, three $3p$ orbitals, and ten $3d$ orbitals, for a total of 14 orbitals. (b) $3s < 3p < 3d$.

page 232 The $6s$ orbital, which starts to hold electrons at element 55, Cs

page 237 We can't conclude anything! Each of the three elements has a different valence electron configuration for its $(n-1)d$ and ns subshells: For Ni, $3d^8 4s^2$; for Pd, $4d^{10}$; and for Pt, $5d^9 6s^1$.

CHAPTER 7

page 251 Atomic number is governed by the number of protons in the nucleus, but atomic weight is governed by both the number of protons and neutrons in the nucleus (electrons are too light to worry about). Co/Ni, Cu/Zn, and Te/I are other pairs of elements whose atomic weights are "off" compared to their atomic numbers.

page 254 The $2p$ electron in a Ne atom would experience a larger Z_{eff} than the $3s$ electron in Na, due to the better shielding by all the $2s$ and $2p$ electrons for Na's $3s$ electron.

page 256 These trends work against each other: Z_{eff} increasing would imply that the valence electrons are pulled tighter in to make the atom smaller, while orbital size "increasing" would imply that atomic size would also increase. The orbital size effect is larger: As you go down a column in the periodic table, atomic size generally increases.

page 259 It is harder to remove another electron from Na^+ , so the process in Equation 7.3 would require more energy and, hence, shorter-wavelength light (see Sections 6.1 and 6.2).

page 260 Since Z_{eff} increases as you go from boron to carbon, we would expect that the first ionization energy would be larger for carbon. Therefore, I_2 for C is even greater.

page 262 The same

page 264 The numbers are the same; the signs are opposite.

page 265 Increasing metallic character is correlated with decreasing ionization energy.

page 268 Since the melting point is so low, we would expect a molecular rather than ionic compound. Thus, so PCl_3 is more likely than ScCl_3 .

page 270 Its low ionization energy

page 272 In the acidic environment of the stomach, carbonate can react to give carbonic acid, which decomposes to water and carbon dioxide gas.

page 274 The longest wavelength of visible light is about 750 nm (Section 6.1). We can assume that this corresponds to the lowest energy of light (since $E = hc/\lambda$) needed to break bonds in hydrogen peroxide. If we plug in 750 nm for λ , we can calculate the energy to break one OO bond in one molecule of hydrogen peroxide, in joules. If we multiply by Avogadro's number, we can calculate how many joules it would take to break a mole of OO bonds in hydrogen peroxide (which is the number one normally finds).

page 275 The halogens all have ground-state electron configurations that are $ns^2 np^5$; sharing an electron with only one other atom makes stable compounds.

page 276 We can estimate the radius to be 1.5 \AA , and the first ionization energy to be 900 kJ/mol . In fact, its bonding radius is indeed 1.5 \AA , and the experimental ionization energy is 920 kJ/mol .

CHAPTER 8

page 290 No. Cl has seven valence electrons. The first and second Lewis symbols are both correct—they both show seven valence electrons, and it doesn't matter which of the four sides has the single electron. The third symbol shows only five electrons and is incorrect.

page 292 CaF_2 is an ionic compound consisting of Ca^{2+} and F^- ions. When Ca and F_2 react to form CaF_2 , each Ca atom loses two electrons to form a Ca^{2+} ion and each fluorine atom in F_2 takes up an electron, forming two F^- ions. Thus, we can say that each Ca atom transfers one electron to each of two fluorine atoms.

page 292 No. Figure 7.9 shows that the alkali metal with the smallest first ionization energy is Cs with a value of +376 kJ/mol. Figure 7.11 shows that the halogen with the largest electron affinity is Cl with a value of -349 kJ/mol. The sum of the two energies gives a positive energy (endothermic). Therefore, all other combinations of alkali metals with halogens will also have positive values.

page 296 Rhodium, Rh

page 297 Weaker. In both H_2 and H_2^+ the two H atoms are principally held together by the electrostatic attractions between the nuclei and the electron(s) concentrated between them. H_2^+ has only one electron between the nuclei whereas H_2 has two and this results in the H—H bond in H_2 being stronger.

page 298 Triple bond. CO_2 has two C—O double bonds. Because the C—O bond in carbon monoxide is shorter, it is likely to be a triple bond.

page 299 Electron affinity measures the energy released when an isolated atom gains an electron to form a 1^- ion. The electronegativity measures the ability of the atom to hold on to its own electrons and attract electrons from other atoms in compounds.

page 300 Polar covalent. The difference in electronegativity between S and O is $3.5 - 2.5 = 1.0$. Based on the examples of F_2 , HF, and LiF, the difference in electronegativity is great enough to introduce some polarity to the bond but not sufficient to cause a complete electron transfer from one atom to the other.

page 302 IF. Because the difference in electronegativity between I and F is greater than that between Cl and F, the magnitude of Q should be greater for IF. In addition, because I has a larger atomic radius than Cl, the bond length in IF is longer than that in ClF. Thus, both Q and r are larger for IF and, therefore, $\mu = Qr$ will be larger for IF.

page 303 Smaller dipole moment for C—H. The magnitude of Q should be similar for C—H and H—I bonds because the difference in electronegativity for each bond is 0.4. The C—H bond length is 1.1 Å and the H—I bond length is 1.6 Å. Therefore $\mu = Qr$ will be greater for H—I because it has a longer bond (larger r).

page 304 OsO_4 . The data suggest that the yellow substance is a molecular species with its low melting and boiling points. Os in OsO_4 has an oxidation number of +8 and Cr in Cr_2O_3 has an oxidation number of +3. In Section 8.4, we learn that a compound with a metal in a high oxidation state should show a high degree of covalence and OsO_4 fits this situation.

page 308 There is probably a better choice of Lewis structure than the one chosen. Because the formal charges must add up to 0 and the formal charge on the F atom is +1, there must be an atom that has a formal charge of -1. Because F is the most electronegative element, we don't expect it to carry a positive formal charge.

page 310 Yes. There are two resonance structures for ozone that each contribute equally to the overall description of the molecule. Each O—O bond is therefore an average of a single bond and a double bond, which is a "one-and-a-half" bond.

page 310 As "one-and-a-third" bonds. There are three resonance structures, and each of the three N—O bonds is single in two of those structures and double in the third. Each bond in the actual ion is an average of these: $(1 + 1 + 2)/3 = 1\frac{1}{3}$.

page 312 No, it will not have multiple resonance structures. We can't "move" the double bonds, as we did in benzene, because the positions of the hydrogen atoms dictate specific positions for the double bonds. We can't write any other reasonable Lewis structures for the molecule.

page 312 The formal charge of each atom is shown here:

The first structure shows each atom with a zero formal charge and therefore it is the dominant Lewis structure. The second one shows a positive formal charge for an oxygen atom, which is a highly electronegative atom, and this is not a favorable situation.

page 315 The atomization of ethane produces $2 \text{C}(g) + 6 \text{H}(g)$. In this process, six C—H bonds and one C—C bond are broken. We can use $6D(\text{C—H})$ to estimate the amount of enthalpy needed to break the six C—H bonds. The difference between that number and the enthalpy of atomization is an estimate of the bond enthalpy of the C—C bond, $D(\text{C—C})$.

page 315 H_2O_2 . From Table 8.4, the bond enthalpy of the O—O single bond in H_2O_2 (146 kJ/mol) is much lower than that of the O=O bond in O_2 (495 kJ/mol). The weaker bond in H_2O_2 is expected to make it more reactive than O_2 .

CHAPTER 9

page 334 Octahedral. Removing two atoms that are opposite each other leads to a square-planar geometry.

page 335 The molecule does not follow the octet rule because it has ten electrons around the central A atom. There are four electron domains around A: two single bonds, one double bond, and one nonbonding pair.

page 336 Each of the three represents a single electron domain in the VSEPR model.

page 339 Yes. Based on one resonance structure, we might expect the electron domain that is due to the double bond to "push" the domains that are due to the single bonds, leading to angles slightly different from 120° . However, we must remember that there are two other equivalent resonance structures—each of the three O atoms has a double bond to N in one of the three resonance structures (Section 8.6). Because of resonance, all three O atoms are equivalent, and they will experience the same amount of repulsion, which leads to bond angles equal to 120° .

page 339 A tetrahedral arrangement of electron domains is preferred because the bond angles are 109.5° compared to 90° . bond angles in a square-planar arrangement of electron domains. The larger bond angles result in smaller repulsions among electron domains and a more stable structure.

page 343 Yes. The C—O and C—S bond dipoles exactly oppose each other, like in CO_2 , but because O and S have different electronegativities, the magnitudes of the bond dipoles will be different. As a consequence, the bond dipoles will not cancel each other and the OCS molecule has a nonzero dipole moment.

page 348 Both p orbitals are perpendicular to the Be—F bond axes.

page 348 (bottom) The unhybridized p orbital is oriented perpendicular to the plane defined by the three sp^2 hybrids (trigonal-planar array of lobes) with one lobe on each side of the plane.

page 353 The molecule should not be linear. Because there are three electron domains around each N atom, we expect sp^2 hybridization and H—N—N angles of approximately 120° . The molecule is expected to be planar; the unhybridized $2p$ orbitals on the N atoms can form a π bond only if all four atoms lie in the same plane. You might notice that there are two ways in which the H atoms can be arranged: They can be both on the same side of the N=N bond or on opposite sides of the N=N bond.

page 358 The σ bond component is formed from sp hybrid orbitals.

page 360 The molecule would fall apart. With one electron in the bonding MO and one in the antibonding MO, there is no net stabilization of the electrons relative to two separate H atoms.

page 362 Yes. In Be_2^+ there would be two electrons in the σ_{2s} MO but only one electron in the σ_{2s}^* MO; therefore, the ion is predicted to have a bond order of $\frac{1}{2}$. It should (and does) exist.

page 366 No. If the σ_{2p} MO were lower in energy than the π_{2p} MOs, we would expect the σ_{2p} MO to hold two electrons and the π_{2p} MOs to hold one electron each, with the same spin. The molecule would therefore be paramagnetic.

CHAPTER 10

page 384 Small

page 385 1470 lb

page 389 It would be halved.

page 390 No—you have to convert T to Kelvin to calculate this properly.

page 392 Avogadro's number, 6.022×10^{23}

page 396 Less dense

page 399 The pressure due to N_2 would be the same, but the total pressure would increase.

page 404 HCl (slowest) $< O_2 < H_2$ (fastest)

page 406 $3/2$

page 409 (a) Decrease, (b) No change

page 410 (b) 100 K and 5 atm

page 411 They do have intermolecular attractions for each other, and they do take up space.

CHAPTER 11

page 430 $CH_4 < CCl_4 < CBr_4$. Because all three molecules are nonpolar, the strength of dispersion forces determines the relative boiling points. Polarizability increases in order of increasing molecular size and molecular weight, $CH_4 < CCl_4 < CBr_4$; hence, the dispersion forces and boiling points increase in the same order.

page 434 $Ca(NO_3)_2$ in water, because calcium nitrate is a strong electrolyte that forms ions and water is a polar molecule with a dipole moment. Ion-dipole forces cannot be present in a CH_3OH/H_2O mixture because CH_3OH does not form ions.

page 438 (a) Both viscosity and surface tension decrease with increasing temperature because of the increased molecular motion. (b) Both properties increase as the strength of intermolecular forces increases.

page 440 Melting (or fusion), endothermic

page 443 CCl_4 . Both compounds are nonpolar; therefore, only dispersion forces exist between the molecules. Because dispersion forces are stronger for the larger, heavier CBr_4 , it has a lower vapor pressure than CCl_4 . The substance with the larger vapor pressure at a given temperature is more volatile.

CHAPTER 12

page 466 Tetragonal. There are two three-dimensional lattices that have a square base with a third vector perpendicular to the base, tetragonal and cubic, but in a cubic lattice the a , b , and c lattice vectors are all of the same length.

page 473 The packing efficiency decreases as the number of nearest neighbors decreases. The structures with the highest packing efficiency, hexagonal and cubic close packing, both have atoms with a coordination number of 12. Body-centered cubic packing, where the coordination number is 8, has a lower packing efficiency, and primitive cubic packing, where the coordination number is 6, has a lower packing efficiency still.

page 474 Interstitial, because boron is a small nonmetal atom that can fit in the voids between the larger palladium atoms

page 481 (a) Gold, Au. Tungsten, W, lies near the middle of the transition metal series where the bands arising from the d orbitals and the s orbital are approximately half-filled. This electron count should fill the bonding orbitals and leave the antibonding orbitals mostly empty. (b) Because both elements have similar numbers of electrons in the bonding orbitals but tungsten has fewer electrons in antibonding orbitals, it will have a higher melting point.

page 482 No. In a crystal the lattice points must be identical. Therefore, if an atom lies on top of a lattice point, then the same type of atom

must lie on all lattice points. In an ionic compound there are at least two different types of atoms, and only one can lie on the lattice points.

page 484 Four. The empirical formula of potassium oxide is K_2O . Rearranging Equation 12.1 we can determine the potassium coordination number to be anion coordination number \times (number of anions per formula unit/number of cations per formula unit) $= 8(1/2) = 4$.

page 494 A condensation polymer. The presence of both $-COOH$ and $-NH_2$ groups allow molecules to react with one another forming $C-N$ bonds and splitting out H_2O .

page 495 As the vinyl acetate content increases more side chain branching occurs which inhibits the formation of crystalline regions thereby lowering the melting point.

page 498 No. The emitted photons have energies that are similar in energy to the band gap of the semiconductor. If the size of the crystals is reduced into the nanometer range, the band gap will increase. However, because 340-nm light falls in the UV region of the electromagnetic spectrum, increasing the energy of the band gap will only shift the light deeper into the UV.

CHAPTER 13

page 514 Energy (or enthalpy) and entropy

page 515 The lattice energy of $NaCl(s)$ must be overcome to separate Na^+ and Cl^- ions and disperse them into a solvent. C_6H_{14} is nonpolar. Interactions between ions and nonpolar molecules tend to be very weak. Thus, the energy required to separate the ions in $NaCl$ is not recovered in the form of ion- C_6H_{14} interactions.

page 517 (a) Separating solvent molecules from each other requires energy and is therefore endothermic. (b) Forming the solute-solvent interactions is exothermic.

page 519 The added solute provides a template for the solid to begin to crystallize from solution, and the excess dissolved solute comes out of solution leaving a saturated solution.

page 522 The solubility in water would be considerably lower because there would no longer be hydrogen bonding with water, which promotes solubility.

page 526 Dissolved gases become less soluble as temperature increases, and they come out of solution, forming bubbles below the boiling point of water.

page 526 230 ppm (1 ppm is 1 part in 10^6); 2.30×10^5 ppb (1 ppb is 1 part in 10^9).

page 528 For dilute aqueous solutions the molality will be nearly equal to the molarity. Molality is the number of moles of solute per kilogram of solvent, whereas molarity is the number moles of solute per liter of solution. Because the solution is dilute, the mass of solvent is essentially equal to the mass of the solution. Furthermore, a dilute aqueous solution will have a density of 1.0 kg/L. Thus, the number of liters of solution and the number of kilograms of solvent will be essentially equal.

page 531 The lowering of the vapor pressure depends on the total solute concentration (Equation 13.11). One mole of $NaCl$ (a strong electrolyte) provides 2 mol of particles (1 mol of Na^+ and 1 mol Cl^-), whereas one mole of (a nonelectrolyte) provides only 1 mol particles.

page 534 Not necessarily; if the solute is a strong or weak electrolyte, it could have a lower molality and still cause an increase of $0.51^\circ C$. The total molality of all the particles in the solution is 1 m.

page 537 The 0.20-m solution is hypotonic with respect to the 0.5-m solution. (A hypotonic solution will have a lower concentration and hence a lower osmotic pressure.)

page 539 They would have the same osmotic pressure because they have the same concentration of particles. (Both are strong electrolytes that are 0.20 M in total ions.)

page 543 The smaller droplets carry negative charges because of the embedded stearate ions and thus repel one another.

CHAPTER 14

page 559 The rate will increase.

page 562 Average rate is for a large time interval; instantaneous rate is for an “instant” in time. Yes, they can have the same numeric value, especially if a plot of concentration versus time is linear.

page 565 (top) Reaction rate is what we measure as a reaction proceeds—change in concentration in time for one or more of the components in the mixture. Reaction rate always has units of concentration per time, usually M/s . A rate constant is what we calculate from reaction rate data, and its magnitude is proportional to the reaction rate, but its units depend on the reaction order. The rate law of a reaction is an equation that relates reaction rate to the rate constant: $\text{Rate} = k[A]^m[B]^n$, for components A and B in the reaction.

page 565 No. Rate is always change in concentration per time; rate constant has units that depend on the form of the rate law.

page 566 (a) The reaction is second order in NO, first order in H_2 , and third order overall. (b) No. Doubling NO concentration will quadruple the rate, but doubling H_2 concentration will merely double the rate.

page 567 No reaction will take place.

page 573 1.25 g

page 575 The half-life will increase.

page 578 No—transition states are by definition not stable.

page 578 The collision may not have occurred with enough energy for reaction to occur, and/or the collision may not have occurred with the proper orientation of reactant molecules to favor product formation.

page 581 Bimolecular

page 585 Most reactions occur in elementary steps; the rate law is governed by the elementary steps, not by their sum (which is the overall balanced equation).

page 587 The odds of three molecules colliding with each other properly to react is very low.

page 590 By lowering the activation energy for the reaction or by increasing the frequency factor

page 591 A homogeneous catalyst will be harder to separate from the reaction mixture than a heterogeneous one.

page 593 People do say this, but we have to be careful. An enzyme-catalyzed reaction will have a lower transition state energy than the uncatalyzed reaction, but the nature of the transition state is probably different than the uncatalyzed version.

CHAPTER 15

page 614 (a) The rates of the forward and reverse reactions. (b) Greater than 1

page 614 When the concentrations of reactants and products are no longer changing

page 617 It does not depend on starting concentrations.

page 617 Units of moles/L are used to calculate K_c ; units of partial pressure are used to calculate K_p .

page 618 0.00140

page 621 It is cubed.

page 623 $K_p = P_{H_2O}$

page 625 $K_c = [NH_4^+][OH^-]/[NH_3]$

page 633 (a) It shifts to the right. (b) It shifts to the left.

page 633 (bottom) It will shift to the left, the side with a larger number of moles of gas.

page 636 As the temperature increases, a larger fraction of molecules in the liquid phase have enough energy to overcome their inter-

molecular attractions and go into the vapor; the evaporation process is endothermic.

page 638 No

CHAPTER 16

page 652 The H^+ ion for acids and the OH^- ion for bases

page 654 CH_3NH_2 is the base because it accepts a H^+ from H_2S as the reaction moves from the left-hand to the right-hand side of the equation.

page 657 As the conjugate base of a strong acid, we would classify ClO_4^- as having negligible basicity.

page 661 pH is defined as $-\log[H^+]$. This quantity will become negative if the H^+ concentration exceeds 1 M, which is possible. Such a solution would be highly acidic.

page 662 $pH = 14.00 - 3.00 = 11.00$. This solution is basic because $pH > 7.0$.

page 665 Both NaOH and $Ba(OH)_2$ are soluble hydroxides. Therefore, the hydroxide concentrations will be 0.001 M for NaOH and 0.002 M for $Ba(OH)_2$. Because the $Ba(OH)_2$ solution has a higher $[OH^-]$, it is more basic and has a higher pH.

page 666 Because CH_3^- is the conjugate base of a substance that has negligible acidity, CH_3^- must be a strong base. Bases stronger than OH^- abstract H^+ from water molecules:

page 668 Oxygen

page 671 Because weak acids typically undergo very little ionization, often less than 1%. Normally we make this assumption and then check its validity based on the concentration of conjugate base formed in the calculation. If it is $\leq 5\%$ of the initial concentration of the weak acid, we can generally use this assumption. If not, we must do an exact calculation.

page 674 This is the acid-dissociation constant for the loss of the third and final proton from H_3PO_4 , corresponding to the equilibrium $HPO_4^{2-} \rightleftharpoons H^+ + PO_4^{3-}$.

page 680 The pK_a value is $-\log K_a = -\log(6.8 \times 10^{-4}) = 3.17$. The pK_b value is $14.00 - pK_a = 14.00 - 3.17 = 10.83$.

page 682 Nitrate is the conjugate base of nitric acid, HNO_3 . The conjugate base of a strong acid does not act as a base, so NO_3^- ions will not affect the pH. Carbonate is the conjugate base of hydrogen carbonate, HCO_3^- , which is a weak acid. The conjugate base of a weak acid acts as a weak base, so CO_3^{2-} ions will increase the pH.

page 686 The increasing acidity going down a group is due mainly to decreasing $H-X$ bond strength. The trend going across a period is due mainly to the increasing electronegativity of X, which weakens the $H-X$ bond.

page 687 $HBrO_3$. For an oxyacid, acidity increases as the electronegativity of the central ion increases, which would make $HBrO_2$ more acidic than HIO_2 . Acidity also increases as the number of oxygens bound to the central atom increases, which would make $HBrO_3$ more acidic than $HBrO_2$. Combining these two relationships we can order these acids in terms of increasing acid-dissociation constant, $HIO_2 < HBrO_2 < HBrO_3$.

page 689 The carboxyl group, $-COOH$

page 690 It must have an unshared pair of electrons that can be shared with another atom.

CHAPTER 17

page 707 (top) The Cl^- ion is the only spectator ion. The pH is determined by the equilibrium $NH_3(aq) + H_2O(l) \rightleftharpoons OH^-(aq) + NH_4^+(aq)$.

page 707 (bottom) HNO_3 and NO_3^- . To form a buffer we need comparable concentrations of a weak acid and its conjugate base.

HNO_3 and NO_3^- will not form a buffer because HNO_3 is a strong acid and the NO_3^- ion is merely a spectator ion.

page 708 (a) The OH^- of NaOH (a strong base) reacts with the acid member of the buffer (CH_3COOH), abstracting a proton. Thus, $[\text{CH}_3\text{COOH}]$ decreases and $[\text{CH}_3\text{COO}^-]$ increases. (b) The H^+ of HCl (a strong acid) reacts with the base member of the buffer $[\text{CH}_3\text{COO}^-]$. Thus, $[\text{CH}_3\text{COO}^-]$ decreases and $[\text{CH}_3\text{COOH}]$ increases.

page 711 A buffer will be most resistant to changes in pH when the concentrations of the weak acid and its conjugate base are equal. When the two are exactly equal the Henderson–Hasselbach equation tells us that the pH of the buffer will be equal to the $\text{p}K_a$ of the weak acid. The $\text{p}K_a$ values of nitrous acid and hypochlorous acid are 3.35 and 7.52, respectively. Thus, HClO would be more suitable for a pH = 7.0 buffer solution. To make a buffer we would also need a salt containing ClO^- , such as NaClO .

page 716 The pH = 7. The neutralization of a strong base with a strong acid gives a salt solution at the equivalence point. The salt contains ions that do not change the pH of water.

page 721 The following titration curve shows the titration of 25 mL of Na_2CO_3 with HCl , both with 0.1 M concentrations. The overall reaction between the two is

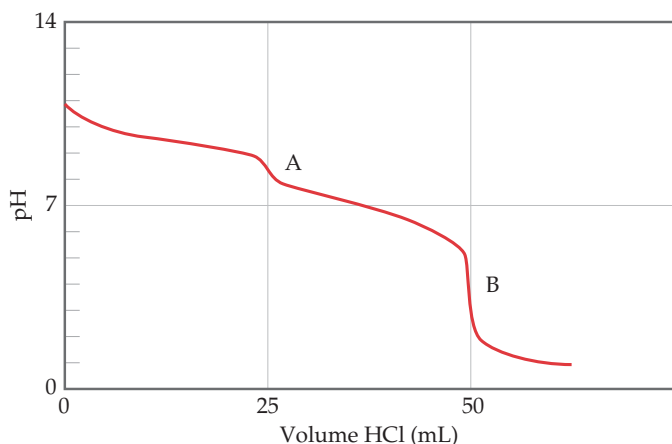

The initial pH (sodium carbonate in water only) is near 11 because CO_3^{2-} is a weak base in water. The graph shows two equivalence points, **A** and **B**. The first point, **A**, is reached at a pH of about 9:

HCO_3^- is weakly basic in water and is a weaker base than the carbonate ion. The second point, **B**, is reached at a pH of about 4:

H_2CO_3 , a weak acid, forms and decomposes to carbon dioxide and water.

page 722 The nearly vertical portion of the titration curve at the equivalence point is smaller for a weak acid–strong base titration; as a result fewer indicators undergo their color change within this narrow range.

page 724 AgCl . Because all three compounds produce the same number of ions, their relative stabilities correspond directly to the K_{sp} values, with the compound with the largest K_{sp} value being the most soluble.

page 734 Amphoteric substances are insoluble in water but dissolve in the presence of sufficient acid or base. Amphiprotic substances can both donate and accept protons.

page 738 The solution must contain one or more of the cations in group 1 of the qualitative analysis scheme, Ag^+ , Pb^{2+} or Hg_2^{2+} .

CHAPTER 18

page 754 Photoionization is a process in which a molecule breaks into ions upon illumination with light; photodissociation is a process in which molecules break up upon illumination with light but the products bear no charge.

page 755 Because those molecules do not absorb light at those wavelengths

page 757 Yes— Cl is neither a product nor a reactant in the overall reaction, and its presence does speed the reaction up.

page 760 SO_2 in the atmosphere reacts with oxygen to form SO_3 . SO_3 in the atmosphere reacts with water in the atmosphere to form H_2SO_4 , sulfuric acid. The sulfuric acid dissolves in water droplets that fall to Earth, causing “acid rain” that has a pH of 4 or so.

page 761 NO_2 photodissociates to NO and O ; the O atoms react with O_2 in the atmosphere to form ozone, which is a key ingredient in photochemical smog.

page 763 Higher humidity means there is more water in the air. Water absorbs infrared light, which we feel as heat. After sundown, the ground that has been warmed earlier in the day reradiates heat out. In locations with higher humidity, this energy is absorbed somewhat by the water and in turn is reradiated to some extent back to the Earth, resulting in warmer temperatures compared to a low-humidity location.

page 764 We need to be below water’s critical point. Therefore, to sublime water we need to be below 0.006 atm. A wide range of temperatures will work for sublimation at this pressure—the most environmentally relevant ones are $-50\text{ }^\circ\text{C}$ to $100\text{ }^\circ\text{C}$.

page 768 The pollutants are capable of being oxidized (either directly by reaction with dissolved oxygen or indirectly by the action of organisms such as bacteria).

page 772 With a catalyst, the reaction is always faster, therefore costing less energy to run. In addition, with a catalyst the reaction may occur readily at a lower temperature, also costing less energy.

page 773 Fossil fuel combustion puts a great deal more CO_2 in the atmosphere right now than any supercritical use of CO_2 . Compared to other (halogenated organic) solvents, supercritical CO_2 is far less toxic to life. Therefore, at present, using CO_2 as a solvent or a reactant in industrial processes is a reasonable choice for environmental sustainability.

page 774 Use room temperature and room pressure; use water as a solvent if possible; use O_2 as the oxidizing agent instead of hydrogen peroxide if possible.

page 775 sp before reaction; sp^2 after reaction

CHAPTER 19

page 787 No, nonspontaneous processes can occur so long as they receive some continuous outside assistance. Examples of nonspontaneous processes with which we may be familiar include the building of a brick wall and the electrolysis of water to form hydrogen gas and oxygen gas.

page 789 No. Just because the system is restored to its original condition doesn’t mean that the surroundings have likewise been restored to their original condition, so it is not necessarily reversible.

page 791 ΔS depends not merely on q but on q_{rev} . Although there are many possible paths that could take a system from its initial to final state, there is always only one reversible isothermal path between two states. Thus, ΔS has only one particular value regardless of the path taken between states.

page 793 Because rusting is a spontaneous process, ΔS_{univ} must be positive. Therefore, the entropy of the surroundings must increase, and that increase must be larger than the entropy decrease of the system.

page 795 $S = 0$, based on Equation 19.5 and the fact that $\ln 1 = 0$.

page 796 A molecule can vibrate (atoms moving relative to one another) and rotate (tumble), whereas a single atom cannot undergo these motions.

page 799 It must be a perfect crystal at 0 K (third law of thermodynamics), which means it has only a single accessible microstate.

page 803 ΔS_{surr} always increases. For simplicity, assume that the process is isothermal. The change in entropy of the surroundings in an isothermal process is $\Delta S_{\text{surr}} = \frac{-q_{\text{sys}}}{T}$. Because the reaction is exothermic, $-q_{\text{sys}}$ is a positive number. Thus, ΔS_{surr} is a positive number and the entropy of the surroundings increases.

page 805 (a) In any spontaneous process the entropy of the universe increases. (b) In any spontaneous process operating at constant temperature, the free energy of the system decreases.

page 806 It indicates that the process to which the thermodynamic quantity refers has taken place under standard conditions, as summarized in Table 19.2.

page 810 Above the boiling point, vaporization is spontaneous, and $\Delta G < 0$. Therefore, $\Delta H - T\Delta S < 0$, and $\Delta H < T\Delta S$.

CHAPTER 20

page 829 Oxygen is first assigned an oxidation number of -2 . Nitrogen must then have a $+3$ oxidation number for the sum of oxidation numbers to equal -1 , the charge of the ion.

page 832 No. Electrons should appear in the two half-reactions but cancel when the half-reactions are added properly.

page 839 Yes. A redox reaction with a positive standard cell potential is spontaneous under standard conditions.

page 840 1 atm pressure of $\text{Cl}_2(\text{g})$ and 1 M concentration of $\text{Cl}^-(\text{aq})$

page 846 Using data from Appendix E, we have $E_{\text{red}}^\circ = -0.126\text{ V}$ for $\text{Pb}^{2+}(\text{aq}) \rightarrow \text{Pb}(\text{s})$ and $E_{\text{red}}^\circ = 0.854\text{ V}$ for $\text{Hg}^{2+}(\text{aq}) \rightarrow \text{Hg}(\text{l})$. Because $\text{Pb}(\text{s})$ has the most negative value for E_{red}° , it is the stronger reducing agent. (See Figure 20.12.) The comparison can also be made by reference to the activity series where Pb lies also above Hg, indicating that Pb is oxidized more readily than Hg. The more readily a substance is oxidized, the stronger it is as a reducing agent.

page 859 Al, Zn. Both are easier to oxidize than Fe.

CHAPTER 21

page 877 The mass number decreases by 4.

page 879 Only the neutron, as it is the only neutral particle listed.

page 883 From Figure 21.4 we can see that each of these four elements has only one stable isotope, and from their atomic numbers we see that they each have an odd number of protons. Given the rarity of stable isotopes with odd numbers of neutrons and protons, we expect that each isotope will possess an even number of neutrons. From their atomic weights we see that this is the case: F (10 neutrons), Na (12 neutrons), Al (14 neutrons), and P (16 neutrons).

page 885 No. Electric and magnetic fields are only effective at accelerating charged particles and a neutron is not charged.

page 889 top Spontaneous radioactive decay is a unimolecular process: $\text{A} \rightarrow \text{Products}$. The rate law that fits this observation is a first-order kinetic rate law, $\text{rate} = k[\text{A}]$. A second-order kinetic process has $\text{rate} = k[\text{A}]^2$ and the elementary reaction is bimolecular: $\text{A} + \text{A} \rightarrow \text{Products}$. A zero-order kinetic process has $\text{rate} = k$, and the rate does not change until the limiting reactant is entirely consumed. The latter two rate laws do not fit a unimolecular process.

page 889 (bottom) (a) Yes; doubling the mass would double the amount of radioactivity of the sample as shown in Equation 21.18. (b) No; changing the mass would not change the half-life as shown in Equation 21.20.

page 892 No. Alpha particles are more readily absorbed by matter than beta or gamma rays. Geiger counters must be calibrated for the radiation they are being used to detect.

page 896 (top) The values in Table 21.7 only reflect the mass of the nucleus, while the atomic mass is the sum of the mass of the nucleus and the electrons. So the atomic mass of iron-56 is $26 \times m_e$ larger than the nuclear mass.

page 896 (bottom) No. Stable nuclei having mass numbers around 100 are the most stable nuclei. They could not form a still more stable nucleus with an accompanying release of energy.

page 905 The absorbed dose is equal to $0.10\text{ J} \times (1\text{ rad}/1 \times 10^{-2}\text{ J}) = 10\text{ rads}$. The effective dosage is calculated by multiplying the absorbed dose by the relative biological effectiveness (RBE) factor, which is 10 for alpha radiation. Thus, the effective dosage is 100 rems.

CHAPTER 22

page 919 (top) No.

page 919 No. N can form triple bonds but P cannot, as it would have to form P_2 .

page 921 H^- , hydride.

page 923 $+1$ for everything except H_2 , for which the oxidation state of H is 0.

page 924 No—it is the volume of Pd that can increase to accommodate hydrogen, not its mass.

page 927 0 for Cl_2 ; -1 for Cl^- ; $+1$ for ClO^-

page 929 They should both be strong, since the central halogen is in the $+5$ oxidation state for both of them. We need to look up the redox potentials to see which ion, BrO_3^- or ClO_3^- , has the larger reduction potential. The ion with the larger reduction potential is the stronger oxidizing agent. BrO_3^- is the stronger oxidizing agent on this basis ($+1.52\text{ V}$ standard reduction potential in acid compared to $+1.47\text{ V}$ for ClO_3^-).

page 931 The standard energy to dissociate one mole of oxygen atoms from one mole of ozone was given as 105 kJ. If we assume, as usual, that one photon will dissociate one molecule, that means the energy of the photons should be 105 kJ per mole (of photons). Using Avogadro's number, we can calculate that one photon would then have $1.744 \times 10^{-19}\text{ J}$ of energy. Using equations from Chapter 6, $c = \lambda\nu$ and $E = h\nu$, we can find that a photon with $1.744 \times 10^{-19}\text{ J}$ of energy will have a wavelength λ of 1140 nm, or $1.14 \times 10^6\text{ m}$, which is in the infrared part of the spectrum.

page 932 HIO_3

page 936 $\text{SO}_3(\text{g}) + \text{H}_2\text{O}(\text{l}) \longrightarrow \text{H}_2\text{SO}_4(\text{l})$

page 940 (a) $+5$ (b) $+3$

page 948 $\text{CO}_2(\text{g})$

page 949 Yes, it must, since CS_2 is a liquid at room temperature and pressure, and CO_2 is a gas.

page 952 Silicon is the element, Si. Silica is SiO_2 . Silicones are polymers that have an $\text{O}-\text{Si}-\text{O}$ backbone and hydrocarbon groups on the Si.

page 953 $+3$

CHAPTER 23

page 965 Sc is the biggest.

page 967 You would have to remove core electrons.

page 968 (top) The larger the distance, the weaker the spin-spin interactions.

page 968 (bottom) Yes, it is a Lewis acid-base interaction; the metal ion is the Lewis acid (electron pair acceptor).

page 972 $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}(\text{aq}) + \text{SCN}^-(\text{aq}) \longrightarrow [\text{Fe}(\text{H}_2\text{O})_5\text{SCN}]^{2+}(\text{aq}) + \text{H}_2\text{O}(\text{l})$

page 974 (a) tetrahedral (b) octahedral

page 976 Bidentate

page 978 Its conjugation (alternating single and double CC bonds)

page 981 No, ammonia cannot engage in linkage isomerism—the only atom that can coordinate to a metal is the nitrogen.

page 985 Both isomers have the same chemical formulas and the same donor atoms on the ligands bonding to the metal ion. The difference is that the *d* isomer has a right-handed “twist” and the *l* isomer has a “left-handed” twist.

page 987 Co is $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^7$. Co^{3+} is $1s^2 2s^2 2p^6 3s^2 3p^6 3d^6$. Co has 3 unpaired electrons; Co^{3+} has 4 unpaired electrons, assuming all 5 *d* orbitals have the same energy.

page 989 It has lost all of the Ti valence electrons; only core electrons remain, and the energy gap between filled and empty orbitals is large, corresponding to light in the ultraviolet, which we cannot perceive as colored.

page 991 Low spin

page 992 The ligands are in the *xy* plane. The d_{xy} orbital has its lobes mostly in that plane, so its energy is higher than d_{xz} and d_{yz} .

CHAPTER 24

page 1007 $\text{C}=\text{N}$, because it is a polar double bond. $\text{C}-\text{H}$ and $\text{C}-\text{C}$ bonds are relatively unreactive.

page 1009 Two $\text{C}-\text{H}$ bonds and two $\text{C}-\text{C}$ bonds

page 1010 The isomers have different properties, as seen in Table 24.3.

page 1015 Only two of the four possible $\text{C}=\text{C}$ bond sites are distinctly different in the linear chain of five carbon atoms with one double bond.

page 1021

page 1025

page 1029 All four groups must be different from one another.

page 1033 No. Breaking the hydrogen bonds between $\text{N}-\text{H}$ and $\text{O}=\text{C}$ groups in a protein by heating causes the α -helix structure to unwind and the β -sheet structure to separate.

page 1037 The α form of the $\text{C}-\text{O}-\text{C}$ linkage. Glycogen serves as a source of energy in the body, which means that the body's enzymes must be able to hydrolyze it to sugars. The enzymes work only on polysaccharides having the α linkage.

CHAPTER 1

Figure 1.1 9

Figure 1.4 Vapor (gas)

Figure 1.5 Molecules of a compound are composed of more than one type of atom, and molecules of an element are composed of only one type of atom.

Figure 1.6 Earth is rich in silicon and aluminum; the human body is rich in carbon and hydrogen

Figure 1.7 They are the same; there are twice as many hydrogen molecules as oxygen molecules, and the hydrogen gas takes up twice the volume of the oxygen gas.

Figure 1.17 True

Figure 1.18 1000

Figure 1.23 The darts would be scattered widely (poor precision) but their average position would be at the center (good accuracy).

CHAPTER 2

Figure 2.3 We know the rays travel from the cathode because of the way the magnetic field diverts the path (b).

Figure 2.4 The electron beam would be deflected downward because of repulsion by the negative plate and attraction toward the positive plate.

Figure 2.8 The beta rays, whose path is diverted away from the negative plate and toward the positive plate, consist of electrons. Because the electrons are much less massive than the alpha particles, their motion is affected more strongly by the electric field.

Figure 2.10 The beam consists of alpha particles, which carry a +2 charge.

Figure 2.14 Based on the periodic trend, we expect that elements that precede a nonreactive gas, as F does, will also be reactive nonmetals. The elements fitting this pattern are H and Cl.

Figure 2.19 The ball-and-stick model more clearly shows the connections between atoms, so we can see the angles at which the atoms are attached in the molecule.

Figure 2.20 The elements are in the following groups: Ag^+ is 1B, Zn^{2+} is 2B, and Sc^{3+} is 3B. Sc^{3+} has the same number of electrons as Ar (element 18).

Figure 2.24 Removing one O atom from the perbromate ion gives the bromate ion, BrO_3^- .

CHAPTER 3

Figure 3.3 The formula CO_2 represents one molecule containing one C and two O atoms, whereas 2 CO represents two molecules, each containing one C atom and one O atom for a total of two C and two O atoms.

Figure 3.8 Both figures show combustion reactions in which the fuel is a hydrocarbon (CH_4 in Figure 3.4 and C_3H_8 in Figure 3.8). In both cases the reactants are the hydrocarbon and O_2 , and the products are CO_2 and H_2O .

Figure 3.9 As shown, $18.0 \text{ g H}_2\text{O} = 1 \text{ mol H}_2\text{O} = 6.02 \times 10^{23}$ molecules H_2O . Thus, $9.00 \text{ g H}_2\text{O} = 0.500 \text{ mol H}_2\text{O} = 3.01 \times 10^{23}$ molecules H_2O .

Figure 3.12 (a) The molar mass of CH_4 , $16.0 \text{ g CH}_4/1 \text{ mol CH}_4$. (b) Avogadro's number, $1 \text{ mol CH}_4/6.02 \times 10^{23}$ formula units CH_4 , where a formula unit in this case is a molecule.

Figure 3.13 The mole ratio is obtained by dividing the molecular weight by the empirical formula weight, Equation 3.11.

Figure 3.17 There are 7 mol O_2 , and each mol O_2 yields 2 mol H_2O . Thus, 14 mol H_2O would have formed.

CHAPTER 4

Figure 4.3 $\text{NaCl}(aq)$ Figure 4.4 K^+ and NO_3^-

Figure 4.9 Two moles of hydrochloric acid are needed to react with each mole of $\text{Mg}(\text{OH})_2$.

Figure 4.19 The volume needed to reach the end point if $\text{Ba}(\text{OH})_2(aq)$ were used would be one-half the volume needed for titration with $\text{NaOH}(aq)$.

CHAPTER 5

Figure 5.1 In the act of throwing, the pitcher transfers energy to the ball, which then becomes kinetic energy of the ball. For a given amount of energy E transferred to the ball, Equation 5.1 tells us that the speed of the ball is $v = \sqrt{2E/m}$ where m is the mass of the ball. Because a baseball has less mass than a bowling ball, it will have a higher speed for a given amount of energy transferred.

Figure 5.2 When she starts going uphill, kinetic energy is converted to potential energy and her speed decreases.

Figure 5.3 The electrostatic potential energy of two oppositely charged particles is negative (Equation 5.2). As the particles become closer, the electrostatic potential energy becomes even more negative—that is, it decreases.

Figure 5.4 Yes, the system is still closed—matter can't escape the system to the surroundings unless the piston is pulled completely out of the cylinder.

Figure 5.5 If $E_{\text{final}} = E_{\text{initial}}$, then $\Delta E = 0$.

Figure 5.6

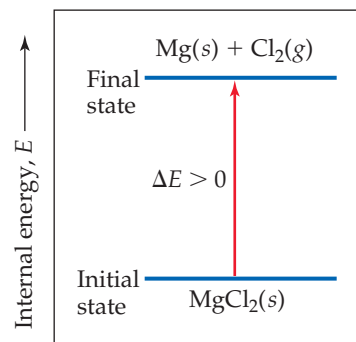

Figure 5.7 No. The sign on w is positive and the sign on q is negative. We need to know the magnitudes of q and w to determine whether $\Delta E = q + w$ is positive or negative.

Figure 5.10 The battery is doing work on the surroundings, so $w < 0$.

Figure 5.11 We need to know whether $\text{Zn}(s)$ or $\text{HCl}(aq)$ is the limiting reagent of the reaction. If it is $\text{Zn}(s)$, then the addition of more Zn will lead to the generation of more $\text{H}_2(g)$ and more work will be done.

Figure 5.17 Endothermic—heat is being added to the system to raise the temperature of the water.

Figure 5.18 Two cups provide more thermal insulation so less heat will escape the system.

Figure 5.19 The stirrer ensures that all of the water in the bomb is at the same temperature.

Figure 5.21 The condensation of $2 \text{H}_2\text{O}(\text{g})$ to $2 \text{H}_2\text{O}(\text{l})$

Figure 5.22 Yes, ΔH_3 would remain the same as it is the enthalpy change for the process $\text{CO}(\text{g}) + \frac{1}{2} \text{O}_2(\text{g}) \longrightarrow \text{CO}_2(\text{g})$.

Figure 5.24 Grams of fat

CHAPTER 6

Figure 6.3 The wavelength of (a) is twice that of (b) and the frequency of (a) is consequently half that of (b). Thus, the wavelength of (b) is 0.50 m and its frequency is 6.0×10^8 cycles/s.

Figure 6.4 The X-ray has a shorter wavelength and, consequently, higher frequency than the red light.

Figure 6.5 The hottest area is the white or yellowish white area in the center.

Figure 6.7 If the tube is not evacuated, the electrons that are freed from the metal surface will strike gas molecules near that surface. As a result, they will become attached to the gas molecules and never arrive at the positive terminal.

Figure 6.12 The $n = 2$ to $n = 1$ transition involves a larger energy change than the $n = 3$ to $n = 2$ transition. (Compare the space differences between the states in the figure.) If the $n = 2$ to $n = 1$ transition produces visible light, the $n = 3$ to $n = 2$ transition must produce radiation of lower energy. The infrared radiation has lower frequency and, hence, lower energy than visible light, whereas the ultraviolet has greater frequency and greater energy. Thus, the $n = 2$ to $n = 1$ transition will produce ultraviolet radiation.

Figure 6.16 The region of highest electron density is where the density of dots is highest, which is near the nucleus.

Figure 6.17 The fourth shell ($n = 4$) would contain four subshells, labeled $4s$, $4p$, $4d$, and $4f$.

Figure 6.18 There would be four maxima and three nodes.

Figure 6.22 (a) The intensity of the color indicates that the probability of finding the electron is greater at the interior of the lobes than on the edges. (b) $2p_x$.

Figure 6.24 The $4d$ and $4f$ subshells are not shown.

CHAPTER 7

Figure 7.1 Row 7—these elements are generally radioactive and not stable.

Figure 7.3 $2s$

Figure 7.6 Bottom and left

Figure 7.7 They get larger, just like the atoms do.

Figure 7.9 Ar; it has a larger Z_{eff} .

Figure 7.10 There is more electron–electron repulsion in the case of oxygen because two electrons have to occupy the same orbital.

Figure 7.11 The halogens (group 7A); it does make sense because we know that they are very stable as anions.

Figure 7.12 Ionization energy—lower ionization energy is correlated with increasing metallic character.

Figure 7.14 Anions are above the lines; cations are below the line.

Figure 7.22 Lilac

CHAPTER 8

Figure 8.1 Covalent

Figure 8.2 Yes, the same sort of reaction should occur between any of the alkali metals and any of the elemental halogens.

Figure 8.3 Cations have a smaller radius than their neutral atoms and anions have a larger radius. Because Na and Cl are in the same row of the periodic table, we would expect Na^+ to have a smaller radius than Cl^- , so we would guess that the larger green spheres represent Cl^- .

Figure 8.4 The distance between ions in KF should be larger than that in NaF and smaller than that in KCl. We would thus expect the lattice energy of KF to be between 701 and 910 kJ/mol.

Figure 8.6 The repulsions between the nuclei would decrease, the attractions between the nuclei and the electrons would decrease, and the repulsions between the electrons would be unaffected.

Figure 8.7 The electronegativity decreases with increasing atomic number.

Figure 8.9 μ will decrease

Figure 8.10 The bonds are not polar enough to cause enough excess electron density on the halogen atom to lead to a red shading.

Figure 8.12 The lengths of the bonds of the outer O atoms to the inner O atom are the same.

Figure 8.13 Yes. The electron densities on the left and right parts of the molecule are the same, indicating that resonance has made the two O—O bonds equivalent to one another.

Figure 8.14 The dashed bonds represent the “half bonds” that result when the two resonance structures are averaged.

Figure 8.15 Exothermic

Figure 8.17 As the bond gets longer, it gets weaker. We would therefore expect a plot of bond enthalpy versus bond length to have a negative slope.

CHAPTER 9

Figure 9.1 The atomic radii (Figure 7.7)

Figure 9.3 Octahedral

Figure 9.7 The electron pair in the bonding domain is attracted toward two nuclear centers, whereas the nonbonding pair is attracted toward just one.

Figure 9.8 90°

Figure 9.9 The nonbonding electron pairs exert a greater repulsive force than the bonding electron pairs.

Figure 9.10 The heads of the arrows point toward regions of highest electron density, as indicated by the red color.

Figure 9.14 As the internuclear distance decreases, nucleus–nucleus repulsion becomes a dominant component of the potential energy.

Figure 9.16 The small lobes of the sp hybrid orbitals are very much smaller in spatial extent and, therefore, provide very little overlap with the F orbitals.

Figure 9.17 Three: one s and two p orbitals

Figure 9.23 The two p orbitals that form the π bond must align, and each of them is perpendicular to the plane of the sp^2 hybrid orbitals.

Figure 9.24 Acetylene, because it has two C—C π bonds, whereas ethylene has one π bond

Figure 9.26 C—H and C—C

Figure 9.33 The σ_{1s}^*

Figure 9.34 The two electrons in the σ_{1s} MO

Figure 9.35 The $1s$ orbitals of Li are small in spatial extent because they experience a strong nuclear attraction. In addition, both the bonding and antibonding MOs formed from them are occupied, so that there is no significant net bonding.

Figure 9.36 Nodal planes between the atoms are found in antibonding MOs.

Figure 9.42 The σ_{2p} and π_{2p} orbitals. Because the σ_{2p} orbital mixes with the σ_{2s} , it is pushed to higher energy and the σ_{2s} is moved to lower energy. The σ_{2p} orbital thus rises above the π_{2p} in energy.

Figure 9.43 F_2 contains four more electrons than N_2 . These electrons go into the antibonding π_{2p}^* orbitals, thus lowering the bond order.

Figure 9.45 Because N_2 has no unpaired electrons, it is diamagnetic. Therefore, it would simply flow down with no tendency to remain in the magnetic field.

Figure 9.46 11. All the electrons in the $n = 2$ level are valence-shell electrons.

CHAPTER 10

Figure 10.2 It will increase.

Figure 10.5 Decrease

Figure 10.6 1520 torr

Figure 10.7 Linear

Figure 10.10 one

Figure 10.11 It is small and inert.

Figure 10.17 About a third

Figure 10.18 Higher speeds are correlated with smaller molar masses (assuming constant T).

Figure 10.20 n , moles of gas

Figure 10.22 Not really— CO_2 is least ideal and does have the largest molar mass, but H_2 , the lightest gas, deviates more from the ideal line than the heavier N_2 .

Figure 10.23 True

Figure 10.25 It would increase.

CHAPTER 11

Figure 11.2 The density in a liquid is much closer to a solid than it is to a gas.

Figure 11.9 Both compounds are nonpolar and incapable of forming hydrogen bonds. Therefore, the boiling point is determined by the dispersion forces, which are stronger for the larger, heavier SnH_4 .

Figure 11.10 The non-hydrogen atom must possess a nonbonding electron pair.

Figure 11.11 There are four electron pairs surrounding oxygen in a water molecule. Two of the electron pairs are used to make covalent bonds to hydrogen within the H_2O molecule, while the other two are available to make hydrogen bonds to neighboring molecules. Because the electron-pair geometry is tetrahedral (four electron domains around the central atom), the $H-O \cdots H$ bond angle is approximately 109° .

Figure 11.19 Wax is a hydrocarbon that cannot form hydrogen bonds. Therefore, coating the inside of tube with wax will dramatically decrease the adhesive forces between water and the tube and change the shape of the water meniscus to an inverted U-shape. Neither wax nor glass can form metallic bonds with mercury so the shape of the mercury meniscus will be qualitatively the same, an inverted U-shape.

Figure 11.21 Because we are dealing with a state function, the energy of going straight from a solid to a gas must be the same as going from a solid to a gas through an intermediate liquid state. Therefore, the heat of sublimation must be equal to the sum of the heat of fusion and the heat of vaporization: $\Delta H_{\text{sub}} = \Delta H_{\text{fus}} + \Delta H_{\text{vap}}$.

Figure 11.24 Increases, because the molecules have more kinetic energy as the temperature increases and can escape more easily

Figure 11.25 All liquids including ethylene glycol reach their normal boiling point when their vapor pressure is equal to atmospheric pressure, 760 torr.

Figure 11.27 Freezing, because for most substances the solid phase is denser than the liquid phase and increasing the pressure will eventually drive a phase transition from the liquid to the solid state (provided the temperature is below the critical temperature)

CHAPTER 12

Figure 12.13 A hexagonal lattice

Figure 12.15 The solvent is the majority component and the solute the minority component. Therefore, there will be more solvent atoms than solute atoms.

Figure 12.17 The samarium atoms sit on the corners of the unit cell so there is only $8 \times (1/8) = 1$ Sm atom per unit cell. Eight of the nine cobalt atoms sit on faces of the unit cell, and the other sits in the middle of the unit cell so there are $8 \times (1/2) + 1 = 5$ Co atoms per unit cell.

Figure 12.19 The atoms are randomly arranged in red gold, which is a substitutional alloy. Purple gold is an intermetallic compound in which the atoms are arranged in a specific ordered pattern.

Figure 12.20 By drawing Lewis structures you can show that there are three (chlorine), two (sulfur), one (phosphorus), and zero (silicon) nonbonding electron pairs per atom.

Figure 12.22 In the fourth period, vanadium and chromium have very similar melting points. Molybdenum and tungsten have the highest melting points in the fifth and sixth periods, respectively. All of these elements are located near the middle of the period where the bonding orbitals are mostly filled and the antibonding orbitals mostly empty.

Figure 12.23 The molecular orbitals become more closely spaced in energy.

Figure 12.24 Potassium has only one valence electron per atom. If we fill the $4s$ band halfway probably a small amount of electron density will leak over and start to fill the $3d$ orbitals as well. The $4p$ orbitals should be empty.

Figure 12.25 Ionic substances cleave because the nearest neighbor interactions switch from attractive to repulsive if the atoms slide so that ions of like charge (cation–cation and anion–anion) touch each other. Metals don't cleave because the atoms are attracted to all other atoms in the crystal through metallic bonding.

Figure 12.26 No, ions of like charge do not touch in an ionic compound because they are repelled from one another. In an ionic compound the cations touch the anions.

Figure 12.28 In NaF there are four Na^+ ions ($12 \times 1/4$) and four F^- ions ($8 \times 1/8 + 6 \times 1/2$) per unit cell. In MgF_2 there are two Mg^{2+} ions ($8 \times 1/8 + 1$) and four F^- ions ($4 \times 1/2 + 2$) per unit cell. In ScF_3 there is one Sc^{3+} ion ($8 \times 1/8$) and three F^- ions ($12 \times 1/4$) per unit cell.

Figure 12.29 The intermolecular forces are stronger in toluene, as shown by its higher boiling point. The molecules pack more efficiently in benzene, which explains its higher melting point, even though the intermolecular forces are weaker.

Figure 12.44 Decrease. As the quantum dots get smaller, the band gap increases and the emitted light shifts to shorter wavelength.

Figure 12.47 Each carbon atom in C_{60} is bonded to three neighboring carbon atoms through covalent bonds. Thus, the bonding is more like graphite, where carbon atoms also bond to three neighbors, than diamond, where carbon atoms bond to four neighbors.

CHAPTER 13

Figure 13.2 Opposite charges attract. The electron-rich O atom of the H_2O molecule, which is the negative end of the dipole, is attracted to the positive Na^+ ion.

Figure 13.3 The negative end of the water dipole (the O) is attracted to the positive Na^+ ion, whereas the positive end of the dipole (the H) is attracted to the negative Cl^- ion.

Figure 13.4 For exothermic solution processes the magnitude of ΔH_{mix} will be larger than the magnitude of $\Delta H_{\text{solute}} + \Delta H_{\text{solvent}}$

Figure 13.8 The dissolving of the crystal and the crystallization by which ions in solution become reattached to the solid

Figure 13.9 If the solution wasn't supersaturated, solute would not crystallize from it.

Figure 13.14 If the partial pressure of a gas over a solution is doubled, the concentration of gas in the solution would double.

Figure 13.15 The slopes increase as the molecular weight increases. The larger the molecular weight, the greater the polarizability of the gas molecules, leading to greater intermolecular attractive forces between gas molecules and water molecules.

Figure 13.18 Looking at where the solubility curves for KCl and NaCl intersect the 80 °C line, we see that the solubility of KCl is about 51 g/100 g H₂O, whereas NaCl has a solubility of about 39 g/100 g H₂O. Thus, KCl is more soluble than NaCl at this temperature.

Figure 13.19 N₂ has the same molecular weight as CO but is nonpolar, so we can predict that its curve will be just below that of CO.

Figure 13.25 The water will move through the semipermeable membrane toward the more concentrated solution. Thus, the liquid level in the left arm will increase.

Figure 13.26 Water will move toward the more concentrated solute solution, which is inside the red blood cells, causing them to undergo hemolysis.

Figure 13.30 The two negatively charged groups both have the composition —CO₂[−].

Figure 13.32 Recall the rule that likes dissolve likes. The oil drop is composed of nonpolar molecules, which interact with the nonpolar part of the stearate ion with dispersion forces.

CHAPTER 14

Figure 14.3 B

Figure 14.4 It decreases.

Figure 14.8 The reaction is first order in CH₃NC.

Figure 14.10 At early times in the reaction; both graphs look linear close to $t = 0$.

Figure 14.17 The energy needed to overcome the energy barrier (the activation energy) looks about twice as large as the overall energy change for the reaction.

Figure 14.23 For the blue curve: The transition states are at the top of the peaks (2) and the intermediate is in the “valley” between the two peaks. For the red curve: The top of the peak is the transition state; no intermediates are shown.

Figure 14.27 Substrate; if products bound tightly, they would not leave and the active site would not be free.

CHAPTER 15

Figure 15.1 The color in the tube stops changing.

Figure 15.2 No

Figure 15.6 The boxes would be approximately the same size.

Figure 15.7 It will be lower; some CO₂ has to react with CaO to make some CaCO₃.

Figure 15.9 500 atm and 400 °C

Figure 15.10 Nitrogen (and some of the added hydrogen) is converted into ammonia.

Figure 15.14 About two to three times faster, based on the graph

Figure 15.15 About 5×10^{-4}

CHAPTER 16

Figure 16.2 Hydrogen bonds

Figure 16.3 $\text{O}^{2-}(\text{aq}) + \text{H}_2\text{O}(\text{l}) \longrightarrow 2 \text{OH}^{-}(\text{aq})$

Figure 16.7 Phenolphthalein changes from colorless, for pH values less than 8, to pink for pH values greater than 10. A pink color indicates $\text{pH} > 10$.

Figure 16.8 Bromothymol blue would be most suitable because it changes pH over a range that brackets $\text{pH} = 7$. Methyl red is not sensitive to

pH changes when $\text{pH} > 6$, while phenolphthalein is not sensitive to pH changes when $\text{pH} < 8$, so neither changes color at $\text{pH} = 7$.

Figure 16.11 Yes. The equilibrium of interest is $\text{H}_3\text{CCOOH} \rightleftharpoons \text{H}^+ + \text{H}_3\text{CCOO}^-$. If the percent dissociation remained constant as the acid concentration increased, the concentration of all three species would increase at the same rate. However, because there are two products and only one reactant, the total concentration of products would increase faster than the concentration of reactants. To offset this effect the percent dissociation decreases as the acid concentration increases.

Figure 16.12 The acidic hydrogens belong to carboxylate (—COOH) groups, whereas the fourth proton bound to oxygen is part of a hydroxyl (—OH) group. In organic acids, like citric acid, the acidic protons are almost always part of a carboxylate group.

Figure 16.13 The nitrogen atom in hydroxylamine accepts a proton to form NH_3OH^+ . As a general rule, nonbonding electron pairs on nitrogen atoms are more basic than nonbonding electron pairs on oxygen atoms.

CHAPTER 17

Figure 17.6 The pH will increase on addition of the base.

Figure 17.7 25.00 mL. The number of moles of added base needed to reach the equivalence point remains the same. Therefore, by doubling the concentration of added base the volume needed to reach the equivalence point is halved.

Figure 17.9 The volume of base needed to reach the equivalence point would not change because this quantity does not depend on the strength of the acid. However, the pH at the equivalence point, which is greater than 7 for a weak acid–strong base titration, would decrease to 7 because hydrochloric acid is a strong acid.

Figure 17.11 The pH at the equivalence point increases (becomes more basic) as the acid becomes weaker. The volume of added base needed to reach the equivalence point remains unchanged.

Figure 17.13 Yes. Any indicator that changes color between $\text{pH} = 3$ and $\text{pH} = 11$ could be used for a strong acid–strong base titration. Methyl red changes color between pH values of approximately 4 and 6.

Figure 17.22 ZnS and CuS would both precipitate on addition of H₂S, preventing separation of the two ions.

Figure 17.23 Yes. CuS would precipitate in step 2 on addition of H₂S to an acidic solution, while the Zn²⁺ ions remained in solution.

CHAPTER 18

Figure 18.1 About 85 km

Figure 18.3 The atmosphere absorbs a significant fraction of solar radiation.

Figure 18.4 The peak value is about 5×10^{12} molecules per cm³. If we use Avogadro's number to convert molecules to moles, and the conversion factor of $1000 \text{ cm}^3 = 1000 \text{ mL} = 1 \text{ L}$, we find that the concentration of ozone at the peak is 8×10^{-9} mole/L.

Figure 18.16 This is ambiguous; both temperature and salinity vary with density in similar ways; but temperature seems to parallel density better. Temperature decreases down to 1000 m, then remains relatively constant; density increases down to 1000 m, and then remains relatively constant.

Figure 18.17 The depth of the aquifer; the nature of the intervening layers (how porous or dense they are)

Figure 18.19 Water is the chemical species that is crossing the membrane, not the ions.

CHAPTER 19

Figure 19.1 Yes, the potential energy of the eggs decreases as they fall.

Figure 19.2 Because the final volume would be less than twice the volume of Flask A, the final pressure would be greater than 0.5 atm.

Figure 19.3 The freezing of liquid water to ice is exothermic.

Figure 19.4 To be truly reversible, the temperature change δT must be infinitesimally small.

Figure 19.8 There are two other independent rotational motions of the H_2O molecule:

Figure 19.9 Ice, because it is the phase in which the molecules are held most rigidly

Figure 19.11 The decrease in the number of molecules due to the formation of new bonds.

Figure 19.13 During a phase change, the temperature remains constant but the entropy change can be large.

Figure 19.14 Based on the three molecules shown, the addition of each C increases S° by 40–45 J/mol-K. Based on this observation, we would predict that $S^\circ(\text{C}_4\text{H}_{10})$ would 310–315 J/mol-K. Appendix C confirms that this is a good prediction: $S^\circ(\text{C}_4\text{H}_{10}) = 310.0 \text{ J/mol-K}$.

Figure 19.16 Spontaneous

Figure 19.17 If we plot progress of the reaction versus free energy, equilibrium is at a minimum point in free energy, as shown in the figure. In that sense, the reaction runs “downhill” until it reaches that minimum point.

CHAPTER 20

Figure 20.1 (a) The bubbling is caused by the hydrogen gas formed in the reaction. (b) The reaction is exothermic, and the heat causes the formation of steam.

Figure 20.2 The permanganate, MnO_4^- , is reduced, as the half-reactions in the text show.

Figure 20.3 The blue color is due to $\text{Cu}^{2+}(\text{aq})$. As this ion is reduced, forming $\text{Cu}(\text{s})$, the blue color fades.

Figure 20.4 The Zn is oxidized and, therefore, serves as the anode of the cell.

Figure 20.5 The electrical balance is maintained in two ways: Anions migrate into the half-cell, and cations migrate out.

Figure 20.9 As the cell operates, H^+ is reduced to H_2 in the cathode half-cell. As H^+ is depleted, the positive Na^+ ions are drawn into the half-cell to maintain electrical balance in the solution.

Figure 20.10 The reduction reaction occurs at the cathode. The substance that is reduced most easily is the one with the larger standard reduction potential, E_{red}° .

Figure 20.12 Oxidation is the loss of electrons. An oxidizing agent causes another substance to lose electrons by gaining them itself. A strong oxidizing agent readily gains electrons, meaning that it is easily reduced.

Figure 20.14 The variable n is the number of moles of electrons transferred in the process.

Figure 20.15 The $\text{Ni}^{2+}(\text{aq})$ and the cations in the salt bridge migrate toward the cathode. The $\text{NO}_3^-(\text{aq})$ and the anions in the salt bridge migrate toward the anode.

Figure 20.19 The cathode consists of $\text{PbO}_2(\text{s})$. Because each oxygen has an oxidation state of -2 , lead must have an oxidation state of $+4$ in this compound.

Figure 20.22 The oxidizing agent of $\text{O}_2(\text{g})$ from the air

CHAPTER 21

Figure 21.2 From Figure 21.2 we see that the belt of stability for a nucleus containing 70 protons lies at approximately 102 neutrons.

Figure 21.4 Only three of the elements with an even number of protons have fewer than three isotopes: He, Be, and C. Note that these three elements are the lightest elements that have an even atomic number. Because they are so light, any change in the number of neutrons will change the neutron/proton ratio significantly. This helps to explain why they do not have more stable isotopes. None of the elements in Figure 21.4 that have an odd number of protons have more than two stable isotopes.

Figure 21.6 6.25 g. After one half-life, the amount of the radioactive material will have dropped to 25.0 g. After two half-lives, it will have dropped to 12.5 g. After three half-lives, it will have dropped to 6.25 g.

Figure 21.19 Because large quantities of water are needed to condense the secondary coolant once it passes through the turbine

Figure 21.21 The United States has the most reactors in operation. China has the most reactors under construction. France generates the largest percentage of its electricity from nuclear power.

Figure 21.24 Alpha rays are less dangerous when outside the body because they cannot penetrate the skin. However, once inside the body they can do great harm to any cells they come in contact with.

CHAPTER 22

Figure 22.5 Beaker on the right is warmer.

Figure 22.6 HF is the most stable, SbH_3 the least stable.

Figure 22.8 More soluble in CCl_4 —the colors are deeper.

Figure 22.9 CF_2

Figure 22.10 Redox reactions: The halides are being oxidized.

Figure 22.14 No

Figure 22.16 Based on this structure—yes, it would have a dipole moment. In fact, if you look it up, hydrogen peroxide’s dipole moment is larger than water’s!

Figure 22.20 They have been converted into water.

Figure 22.21 Formally they could both be $+2$. If we consider that the central sulfur is like SO_4^{2-} , however, then the central sulfur would be $+6$, like SO_4^{2-} , and then the terminal sulfur would be -2 .

Figure 22.22 Nitrite

Figure 22.23 Longer

Figure 22.26 The NO double bond

Figure 22.28 In P_4O_6 the electron domains about the P atoms are trigonal pyramidal; in P_4O_{10} the electron domains about the P atoms are tetrahedral.

Figure 22.33 The minimum temperature should be the melting point of silicon; the temperature of the heating coil should not be so high that the silicon rod starts to melt outside the zone of the heating coil.

CHAPTER 23

Figure 23.3 Zn (it is colorless)

Figure 23.4 The increase parallels the linear increase in valence electron count.

Figure 23.5 All the electron spins would align with the direction of the magnetic field.

Figure 23.9 109.5 degrees for the tetrahedral Zn complex; 90 degrees for the square-planar Pt complex

Figure 23.13 4 for both (assuming no other ligands come in to bind)

Figure 23.15 In the same place as O_2

Figure 23.16 The peak with a maximum at 650 nm, the longest wavelength and lowest energy

Figure 23.21 The *cis* one

Figure 23.24 Larger, since ammonia can displace water

Figure 23.26 The peak would stay in the same position in terms of wavelength, but its absorbance would decrease.

Figure 23.28 $d_{x^2-y^2}$ and d_{z^2}

Figure 23.29 Convert the wavelength of light, 495 nm, into energy in joules using $E = hc/\lambda$.

Figure 23.30 It would be to the right of the “yellow” member of the series, but the energy gap between filled and empty d orbitals would be even larger than that of the “yellow” one.

Figure 23.34 That orbital has the lobes that point directly at the ligands.

CHAPTER 24

Figure 24.1 Tetrahedral

Figure 24.2 The OH group is polar whereas the CH₃ group is nonpolar. Hence, adding CH₃ will (a) reduce the substance’s solubility in polar solvents and (b) increase its solubility in nonpolar solvents.

Figure 24.5 C_nH_{2n}, because there are no CH₃ groups, each carbon has two hydrogens.

Figure 24.7 Just one

Figure 24.9 Intermediates are minima and transition states are maxima on energy profiles.

Figure 24.14 Both lactic acid and citric acid

Figure 24.15 No, because there are not four different groups around any carbon

Figure 24.18 Those labeled “basic amino acids,” which have basic side groups that are protonated at pH 7

Figure 24.25 The long hydrocarbon chains, which are nonpolar

Figure 24.27 The polar parts of the phospholipids seek to interact with water whereas the nonpolar parts seek to interact with other nonpolar substances and to avoid water.

Figure 24.29 Negative charge because of charge on phosphate groups

Figure 24.31 GC because each base has three hydrogen bonding sites, whereas there are only two in AT

GLOSSARY

absolute zero The lowest attainable temperature; 0 K on the Kelvin scale and -273.15 °C on the Celsius scale. (Section 1.4)

absorption spectrum A pattern of variation in the amount of light absorbed by a sample as a function of wavelength. (Section 23.5)

accuracy A measure of how closely individual measurements agree with the correct value. (Section 1.5)

acid A substance that is able to donate a H^+ ion (a proton) and, hence, increases the concentration of $H^+(aq)$ when it dissolves in water. (Section 4.3)

acid-dissociation constant (K_a) An equilibrium constant that expresses the extent to which an acid transfers a proton to solvent water. (Section 16.6)

acidic anhydride (acidic oxide) An oxide that forms an acid when added to water; soluble non-metal oxides are acidic anhydrides. (Section 22.5)

acidic oxide (acidic anhydride) An oxide that either reacts with a base to form a salt or with water to form an acid. (Section 22.5)

acid rain Rainwater that has become excessively acidic because of absorption of pollutant oxides, notably SO_3 , produced by human activities. (Section 18.2)

actinide element Element in which the 5f orbitals are only partially occupied. (Section 6.8)

activated complex (transition state) The particular arrangement of atoms found at the top of the potential-energy barrier as a reaction proceeds from reactants to products. (Section 14.5)

activation energy (E_a) The minimum energy needed for reaction; the height of the energy barrier to formation of products. (Section 14.5)

active site Specific site on a heterogeneous catalyst or an enzyme where catalysis occurs. (Section 14.7)

activity The decay rate of a radioactive material, generally expressed as the number of disintegrations per unit time. (Section 21.4)

activity series A list of metals in order of decreasing ease of oxidation. (Section 4.4)

addition polymerization Polymerization that occurs through coupling of monomers with one another, with no other products formed in the reaction. (Section 12.8)

addition reaction A reaction in which a reagent adds to the two carbon atoms of a carbon-carbon multiple bond. (Section 24.3)

adsorption The binding of molecules to a surface. (Section 14.7)

alcohol An organic compound obtained by substituting a hydroxyl group ($-OH$) for a hydrogen on a hydrocarbon. (Sections 2.9 and 24.4)

aldehyde An organic compound that contains a carbonyl group ($C=O$) to which at least one hydrogen atom is attached. (Section 24.4)

alkali metals Members of group 1A in the periodic table. (Section 7.7)

alkaline earth metals Members of group 2A in the periodic table. (Section 7.7)

alkanes Compounds of carbon and hydrogen containing only carbon-carbon single bonds. (Sections 2.9 and 24.2)

alkenes Hydrocarbons containing one or more carbon-carbon double bonds. (Section 24.2)

alkyl group A group that is formed by removing a hydrogen atom from an alkane. (Section 25.3)

alkynes Hydrocarbons containing one or more carbon-carbon triple bonds. (Section 24.2)

alloy A substance that has the characteristic properties of a metal and contains more than one element. Often there is one principal metallic component, with other elements present in smaller amounts. Alloys may be homogeneous or heterogeneous. (Section 12.3)

alpha decay A type of radioactive decay in which an atomic nucleus emits an alpha particle and thereby transforms (or "decays") into an atom with a mass number 4 less and atomic number 2 less. (Section 21.1)

alpha (α) helix A protein structure in which the protein is coiled in the form of a helix with hydrogen bonds between $C=O$ and $N-H$ groups on adjacent turns. (Section 24.7)

alpha particles Particles that are identical to helium-4 nuclei, consisting of two protons and two neutrons, symbol 4_2He or ${}^4_2\alpha$. (Section 21.1)

amide An organic compound that has an NR_2 group attached to a carbonyl. (Section 24.4)

amine A compound that has the general formula R_3N , where R may be H or a hydrocarbon group. (Section 16.7)

amino acid A carboxylic acid that contains an amino ($-NH_2$) group attached to the carbon atom adjacent to the carboxylic acid ($-COOH$) functional group. (Section 24.7)

amorphous solid A solid whose molecular arrangement lacks the regularly repeating long-range pattern of a crystal. (Section 12.2)

amphiprotic Refers to the capacity of a substance to either add or lose a proton (H^+). (Section 16.2)

amphoteric oxides and hydroxides Oxides and hydroxides that are only slightly soluble in water but that dissolve in either acidic or basic solutions. (Section 17.5)

angstrom A common non-SI unit of length, denoted \AA , that is used to measure atomic dimensions: $1 \text{\AA} = 10^{-10} \text{ m}$. (Section 2.3)

anion A negatively charged ion. (Section 2.7)

anode An electrode at which oxidation occurs. (Section 20.3)

antibonding molecular orbital A molecular orbital in which electron density is concentrated outside the region between the two nuclei of bonded atoms. Such orbitals, designated as σ^* or π^* , are less stable (of higher energy) than bonding molecular orbitals. (Section 9.7)

antiferromagnetism A form of magnetism in which unpaired electron spins on adjacent sites point in opposite directions and cancel each other's effects. (Section 23.1)

aqueous solution A solution in which water is the solvent. (Chapter 4: Introduction)

aromatic hydrocarbons Hydrocarbon compounds that contain a planar, cyclic arrangement of carbon atoms linked by both σ and delocalized π bonds. (Section 24.2)

Arrhenius equation An equation that relates the rate constant for a reaction to the frequency factor, A , the activation energy, E_a , and the temperature, T : $k = Ae^{-E_a/RT}$. In its logarithmic form it is written $\ln k = -E_a/RT + \ln A$. (Section 14.5)

atmosphere (atm) A unit of pressure equal to 760 torr; 1 atm = 101.325 kPa. (Section 10.2)

atom The smallest representative particle of an element. (Sections 1.1 and 2.1)

atomic mass unit (amu) A unit based on the value of exactly 12 amu for the mass of the isotope of carbon that has six protons and six neutrons in the nucleus. (Sections 2.3 and 3.3)

atomic number The number of protons in the nucleus of an atom of an element. (Section 2.3)

atomic radius An estimate of the size of an atom. See **bonding atomic radius**. (Section 7.3)

atomic weight The average mass of the atoms of an element in atomic mass units (amu); it is numerically equal to the mass in grams of one mole of the element. (Section 2.4)

autoionization The process whereby water spontaneously forms low concentrations of $H^+(aq)$ and $OH^-(aq)$ ions by proton transfer from one water molecule to another. (Section 16.3)

Avogadro's hypothesis A statement that equal volumes of gases at the same temperature and pressure contain equal numbers of molecules. (Section 10.3)

Avogadro's law A statement that the volume of a gas maintained at constant temperature and pressure is directly proportional to the number of moles of the gas. (Section 10.3)

Avogadro's number (N_A) The number of ${}^{12}C$ atoms in exactly 12 g of ${}^{12}C$; it equals $6.022 \times 10^{23} \text{ mol}^{-1}$. (Section 3.4)

band An array of closely spaced molecular orbitals occupying a discrete range of energy. (Section 12.4)

band gap The energy gap between a fully occupied band called a valence band and an empty band called the conduction band. (Section 12.7)

band structure The electronic structure of a solid, defining the allowed ranges of energy for electrons in a solid. (Section 12.7)

bar A unit of pressure equal to 10^5 Pa. (Section 10.2)

base A substance that is an H^+ acceptor; a base produces an excess of $OH^-(aq)$ ions when it dissolves in water. (Section 4.3)

base-dissociation constant (K_b) An equilibrium constant that expresses the extent to which a base reacts with solvent water, accepting a proton and forming $OH^-(aq)$. (Section 16.7)

basic anhydride (basic oxide) An oxide that forms a base when added to water; soluble metal oxides are basic anhydrides. (Section 22.5)

basic oxide (basic anhydride) An oxide that either reacts with water to form a base or reacts with an acid to form a salt and water. (Section 22.5)

battery A self-contained electrochemical power source that contains one or more voltaic cells. (Section 20.7)

becquerel The SI unit of radioactivity. It corresponds to one nuclear disintegration per second. (Section 21.4)

Beer's law The light absorbed by a substance (A) equals the product of its extinction coefficient (ϵ), the path length through which the light passes (b), and the molar concentration of the substance (c): $A = \epsilon bc$. (Section 14.2)

beta emission A nuclear decay process where a beta particle is emitted from the nucleus; also called beta decay. (Section 21.1)

beta particles Energetic electrons emitted from the nucleus, symbol ${}_{-1}^0\text{e}$. (Section 21.1)

beta sheet A structural form of protein in which two strands of amino acids are hydrogen-bonded together in a zipperlike configuration. (Section 24.7)

bidentate ligand A ligand in which two linked coordinating atoms are bound to a metal. (Section 23.3)

bimolecular reaction An elementary reaction that involves two molecules. (Section 14.6)

biochemistry The study of the chemistry of living systems. (Chapter 24: Introduction)

biodegradable Organic material that bacteria are able to oxidize. (Section 18.4)

body-centered lattice A crystal lattice in which the lattice points are located at the center and corners of each unit cell. (Section 12.2)

bomb calorimeter A device for measuring the heat evolved in the combustion of a substance under constant-volume conditions. (Section 5.5)

bond angles The angles made by the lines joining the nuclei of the atoms in a molecule. (Section 9.1)

bond dipole The dipole moment that is due to unequal electron sharing between two atoms in a covalent bond. (Section 9.3)

bond enthalpy The enthalpy change, ΔH , required to break a particular bond when the substance is in the gas phase. (Section 8.8)

bonding atomic radius The radius of an atom as defined by the distances separating it from other atoms to which it is chemically bonded. (Section 7.3)

bonding molecular orbital A molecular orbital in which the electron density is concentrated in the internuclear region. The energy of a bonding molecular orbital is lower than the energy of the separate atomic orbitals from which it forms. (Section 9.7)

bonding pair In a Lewis structure a pair of electrons that is shared by two atoms. (Section 9.2)

bond length The distance between the centers of two bonded atoms. (Section 8.3)

bond order The number of bonding electron pairs shared between two atoms, minus the number

of antibonding electron pairs: $\text{bond order} = (\text{number of bonding electrons} - \text{number of antibonding electrons})/2$. (Section 9.7)

bond polarity A measure of the degree to which the electrons are shared unequally between two atoms in a chemical bond. (Section 8.4)

boranes Covalent hydrides of boron. (Section 22.11)

Born-Haber cycle A thermodynamic cycle based on Hess's law that relates the lattice energy of an ionic substance to its enthalpy of formation and to other measurable quantities. (Section 8.2)

Boyle's law A law stating that at constant temperature, the product of the volume and pressure of a given amount of gas is a constant. (Section 10.3)

Brønsted-Lowry acid A substance (molecule or ion) that acts as a proton donor. (Section 16.2)

Brønsted-Lowry base A substance (molecule or ion) that acts as a proton acceptor. (Section 16.2)

buffer capacity The amount of acid or base a buffer can neutralize before the pH begins to change appreciably. (Section 17.2)

buffered solution (buffer) A solution that undergoes a limited change in pH upon addition of a small amount of acid or base. (Section 17.2)

calcination The heating of an ore to bring about its decomposition and the elimination of a volatile product. For example, a carbonate ore might be calcined to drive off CO_2 . (Section 23.2)

calorie A unit of energy, it is the amount of energy needed to raise the temperature of 1 g of water by 1°C from 14.5°C to 15.5°C . A related unit is the joule: $1 \text{ cal} = 4.184 \text{ J}$. (Section 5.1)

calorimeter An apparatus that measures the heat released or absorbed in a chemical or physical process. (Section 5.5)

calorimetry The experimental measurement of heat produced in chemical and physical processes. (Section 5.5)

capillary action The process by which a liquid rises in a tube because of a combination of adhesion to the walls of the tube and cohesion between liquid particles. (Section 11.3)

carbide A binary compound of carbon with a metal or metalloid. (Section 22.9)

carbohydrates A class of substances formed from polyhydroxy aldehydes or ketones. (Section 24.8)

carbon black A microcrystalline form of carbon. (Section 22.9)

carbonyl group The $\text{C}=\text{O}$ double bond, a characteristic feature of several organic functional groups, such as ketones and aldehydes. (Section 24.4)

carboxylic acid A compound that contains the $-\text{COOH}$ functional group. (Sections 16.10 and 24.4)

catalyst A substance that changes the speed of a chemical reaction without itself undergoing a permanent chemical change in the process. (Section 14.7)

cathode An electrode at which reduction occurs. (Section 20.3)

cathode rays Streams of electrons that are produced when a high voltage is applied to electrodes in an evacuated tube. (Section 2.2)

cathodic protection A means of protecting a metal against corrosion by making it the cathode in

a voltaic cell. This can be achieved by attaching a more easily oxidized metal, which serves as an anode, to the metal to be protected. (Section 20.8)

cation A positively charged ion. (Section 2.7)

cell potential The potential difference between the cathode and anode in an electrochemical cell; it is measured in volts: $1 \text{ V} = 1 \text{ J/C}$. Also called electromotive force. (Section 20.4)

cellulose A polysaccharide of glucose; it is the major structural element in plant matter. (Section 24.8)

Celsius scale A temperature scale on which water freezes at 0° and boils at 100° at sea level. (Section 1.4)

chain reaction A series of reactions in which one reaction initiates the next. (Section 21.7)

changes of state Transformations of matter from one state to a different one, for example, from a gas to a liquid. (Section 1.3)

charcoal A form of carbon produced when wood is heated strongly in a deficiency of air. (Section 22.9)

Charles's law A law stating that at constant pressure, the volume of a given quantity of gas is proportional to absolute temperature. (Section 10.3)

chelate effect The generally larger formation constants for polydentate ligands as compared with the corresponding *monodentate* ligands. (Section 23.3)

chelating agent A polydentate ligand that is capable of occupying two or more sites in the coordination sphere. (Section 23.3)

chemical bond A strong attractive force that exists between atoms in a molecule. (Section 8.1)

chemical changes Processes in which one or more substances are converted into other substances; also called **chemical reactions**. (Section 1.3)

chemical equation A representation of a chemical reaction using the chemical formulas of the reactants and products; a balanced chemical equation contains equal numbers of atoms of each element on both sides of the equation. (Section 3.1)

chemical equilibrium A state of dynamic balance in which the rate of formation of the products of a reaction from the reactants equals the rate of formation of the reactants from the products; at equilibrium the concentrations of the reactants and products remain constant. (Section 4.1; Chapter 15: Introduction)

chemical formula A notation that uses chemical symbols with numerical subscripts to convey the relative proportions of atoms of the different elements in a substance. (Section 2.6)

chemical kinetics The area of chemistry concerned with the speeds, or rates, at which chemical reactions occur. (Chapter 14: Introduction)

chemical nomenclature The rules used in naming substances. (Section 2.8)

chemical properties Properties that describe a substance's composition and its reactivity; how the substance reacts or changes into other substances. (Section 1.3)

chemical reactions Processes in which one or more substances are converted into other substances; also called **chemical changes**. (Section 1.3)

chemistry The scientific discipline that studies the composition, properties, and transformations of matter. (Chapter 1: Introduction)

chiral A term describing a molecule or an ion that cannot be superimposed on its mirror image. (Sections 23.4 and 24.5)

chlorofluorocarbons Compounds composed entirely of chlorine, fluorine, and carbon. (Section 18.3)

chlorophyll A plant pigment that plays a major role in conversion of solar energy to chemical energy in photosynthesis. (Section 23.3)

cholesteric liquid crystalline phase A liquid crystal formed from flat, disc-shaped molecules that align through a stacking of the molecular discs. (Section 11.7)

coal A naturally occurring solid containing hydrocarbons of high molecular weight, as well as compounds containing sulfur, oxygen, and nitrogen. (Section 5.8)

colligative property A property of a solvent (vapor-pressure lowering, freezing-point lowering, boiling-point elevation, osmotic pressure) that depends on the total concentration of solute particles present. (Section 13.5)

collision model A model of reaction rates based on the idea that molecules must collide to react; it explains the factors influencing reaction rates in terms of the frequency of collisions, the number of collisions with energies exceeding the activation energy, and the probability that the collisions occur with suitable orientations. (Section 14.5)

colloids (colloidal dispersions) Mixtures containing particles larger than normal solutes but small enough to remain suspended in the dispersing medium. (Section 13.6)

combination reaction A chemical reaction in which two or more substances combine to form a single product. (Section 3.2)

combustion reaction A chemical reaction that proceeds with evolution of heat and usually also a flame; most combustion involves reaction with oxygen, as in the burning of a match. (Section 3.2)

common-ion effect A shift of an equilibrium induced by an ion common to the equilibrium. For example, added Na_2SO_4 decreases the solubility of the slightly soluble salt BaSO_4 , or added NaF decreases the percent ionization of HF . (Section 17.1)

complementary colors Colors that, when mixed in proper proportions, appear white or colorless. (Section 23.5)

complete ionic equation A chemical equation in which dissolved strong electrolytes (such as dissolved ionic compounds) are written as separate ions. (Section 4.2)

complex ion (complex) An assembly of a metal ion and the Lewis bases (ligands) bonded to it. (Section 17.5)

compound A substance composed of two or more elements united chemically in definite proportions. (Section 1.2)

compound semiconductor A semiconducting material formed from two or more elements. (Section 12.7)

concentration The quantity of solute present in a given quantity of solvent or solution. (Section 4.5)

concentration cell A voltaic cell containing the same electrolyte and the same electrode materials in both the anode and cathode compartments. The emf of the cell is derived from a difference in the

concentrations of the same electrolyte solutions in the compartments. (Section 20.6)

condensation polymerization Polymerization in which molecules are joined together through condensation reactions. (Section 12.8)

condensation reaction A chemical reaction in which a small molecule (such as a molecule of water) is split out from between two reacting molecules. (Sections 12.6 and 22.8)

conduction band A band of molecular orbitals lying higher in energy than the occupied valence band and distinctly separated from it. (Section 12.7)

conjugate acid A substance formed by addition of a proton to a Brønsted–Lowry base. (Section 16.2)

conjugate acid–base pair An acid and a base, such as H_2O and OH^- , that differ only in the presence or absence of a proton. (Section 16.2)

conjugate base A substance formed by the loss of a proton from a Brønsted–Lowry acid. (Section 16.2)

continuous spectrum A spectrum that contains radiation distributed over all wavelengths. (Section 6.3)

conversion factor A ratio relating the same quantity in two systems of units that is used to convert the units of measurement. (Section 1.6)

coordination compound A compound containing a metal ion bonded to a group of surrounding molecules or ions that act as ligands. (Section 23.2)

coordination number The number of adjacent atoms to which an atom is directly bonded. In a complex the coordination number of the metal ion is the number of donor atoms to which it is bonded. (Sections 12.37 and 24.2)

coordination sphere The metal ion and its surrounding ligands. (Section 23.2)

coordination-sphere isomers Structural isomers of coordination compounds in which the ligands within the coordination sphere differ. (Section 23.4)

copolymer A complex polymer resulting from the polymerization of two or more chemically different monomers. (Section 12.8)

core electrons The electrons that are not in the outermost shell of an atom. (Section 6.8)

corrosion The process by which a metal is oxidized by substances in its environment. (Section 20.8)

covalent bond A bond formed between two or more atoms by a sharing of electrons. (Section 8.1)

covalent-network solids Solids in which the units that make up the three-dimensional network are joined by covalent bonds. (Section 12.1)

critical mass The amount of fissionable material necessary to maintain a nuclear chain reaction. (Section 21.7)

critical pressure The pressure at which a gas at its critical temperature is converted to a liquid state. (Section 11.4)

critical temperature The highest temperature at which it is possible to convert the gaseous form of a substance to a liquid. The critical temperature increases with an increase in the magnitude of intermolecular forces. (Section 11.4)

crystal-field theory A theory that accounts for the colors and the magnetic and other properties of transition-metal complexes in terms of the splitting of the energies of metal ion d orbitals by the electrostatic interaction with the ligands. (Section 23.6)

crystal lattice An imaginary network of points on which the repeating motif of a solid may be imagined to be laid down so that the structure of the crystal is obtained. The motif may be a single atom or a group of atoms. Each lattice point represents an identical environment in the crystal. (Section 12.2)

crystalline solid (crystal) A solid whose internal arrangement of atoms, molecules, or ions possesses a regularly repeating pattern in any direction through the solid. (Section 12.2)

crystallization The process in which molecules, ions, or atoms come together to form a crystalline solid. (Section 13.2)

cubic close packing A crystal structure where the atoms are packed together as close as possible, and the close-packed layers of atoms adopt a three-layer repeating pattern that leads to a face-centered cubic unit cell. (Section 12.3)

curie A measure of radioactivity: 1 curie = 3.7×10^{10} nuclear disintegrations per second. (Section 21.4)

cycloalkanes Saturated hydrocarbons of general formula C_nH_{2n} in which the carbon atoms form a closed ring. (Section 24.2)

Dalton's law of partial pressures A law stating that the total pressure of a mixture of gases is the sum of the pressures that each gas would exert if it were present alone. (Section 10.6)

$d-d$ transition The transition of an electron in a transition-metal compound from a lower-energy d orbital to a higher-energy d orbital. (Section 23.6)

decomposition reaction A chemical reaction in which a single compound reacts to give two or more products. (Section 3.2)

degenerate A situation in which two or more orbitals have the same energy. (Section 6.7)

delocalized electrons Electrons that are spread over a number of atoms in a molecule or a crystal rather than localized on a single atom or a pair of atoms. (Section 9.6)

density The ratio of an object's mass to its volume. (Section 1.4)

deoxyribonucleic acid (DNA) A polynucleotide in which the sugar component is deoxyribose. (Section 24.10)

desalination The removal of salts from seawater, brine, or brackish water to make it fit for human consumption. (Section 18.4)

deuterium The isotope of hydrogen whose nucleus contains a proton and a neutron: ${}^2_1\text{H}$. (Section 22.2)

dextrorotatory, or merely dextro or d A term used to label a chiral molecule that rotates the plane of polarization of plane-polarized light to the right (clockwise). (Section 23.4)

diamagnetism A type of magnetism that causes a substance with no unpaired electrons to be weakly repelled from a magnetic field. (Section 9.8)

diatomic molecule A molecule composed of only two atoms. (Section 2.6)

diffusion The spreading of one substance through a space occupied by one or more other substances. (Section 10.8)

dilution The process of preparing a less concentrated solution from a more concentrated one by adding solvent. (Section 4.5)

dimensional analysis A method of problem solving in which units are carried through all calculations. Dimensional analysis ensures that the final answer of a calculation has the desired units. (Section 1.6)

dipole A molecule with one end having a partial negative charge and the other end having a partial positive charge; a polar molecule. (Section 8.4)

dipole-dipole force A force that becomes significant when polar molecules come in close contact with one another. The force is attractive when the positive end of one polar molecule approaches the negative end of another. (Section 11.2)

dipole moment A measure of the separation and magnitude of the positive and negative charges in polar molecules. (Section 8.4)

dispersion forces Intermolecular forces resulting from attractions between induced dipoles. Also called London dispersion forces. (Section 11.2)

displacement reaction A reaction in which an element reacts with a compound, displacing an element from it. (Section 4.4)

donor atom The atom of a ligand that bonds to the metal. (Section 23.2)

doping Incorporation of a hetero atom into a solid to change its electrical properties. For example, incorporation of P into Si. (Section 12.7)

double bond A covalent bond involving two electron pairs. (Section 8.3)

double helix The structure for DNA that involves the winding of two DNA polynucleotide chains together in a helical arrangement. The two strands of the double helix are complementary in that the organic bases on the two strands are paired for optimal hydrogen bond interaction. (Section 24.10)

dynamic equilibrium A state of balance in which opposing processes occur at the same rate. (Section 11.5)

effective nuclear charge The net positive charge experienced by an electron in a many-electron atom; this charge is not the full nuclear charge because there is some shielding of the nucleus by the other electrons in the atom. (Section 7.2)

effusion The escape of a gas through an orifice or hole. (Section 10.8)

elastomer A material that can undergo a substantial change in shape via stretching, bending, or compression and return to its original shape upon release of the distorting force. (Section 12.6)

electrochemistry The branch of chemistry that deals with the relationships between electricity and chemical reactions. (Chapter 20: Introduction)

electrolysis reaction A reaction in which a nonspontaneous redox reaction is brought about by the passage of current under a sufficient external electrical potential. The devices in which electrolysis reactions occur are called electrolytic cells. (Section 20.9)

electrolyte A solute that produces ions in solution; an electrolytic solution conducts an electric current. (Section 4.1)

electrolytic cell A device in which a nonspontaneous oxidation-reduction reaction is caused to occur by passage of current under a sufficient external electrical potential. (Section 20.9)

electromagnetic radiation (radiant energy) A form of energy that has wave characteristics and that propagates through a vacuum at the characteristic speed of 3.00×10^8 m/s. (Section 6.1)

electrometallurgy The use of electrolysis to reduce or refine metals. (Section 20.9)

electromotive force (emf) A measure of the driving force, or *electrical pressure*, for the completion of an electrochemical reaction. Electromotive force is measured in volts: $1 \text{ V} = 1 \text{ J/C}$. Also called the cell potential. (Section 20.4)

electron A negatively charged subatomic particle found outside the atomic nucleus; it is a part of all atoms. An electron has a mass $1/1836$ times that of a proton. (Section 2.3)

electron affinity The energy change that occurs when an electron is added to a gaseous atom or ion. (Section 7.5)

electron capture A mode of radioactive decay in which an inner-shell orbital electron is captured by the nucleus. (Section 21.1)

electron configuration The arrangement of electrons in the orbitals of an atom or molecule (Section 6.8)

electron density The probability of finding an electron at any particular point in an atom; this probability is equal to ψ^2 , the square of the wave function. Also called the probability density. (Section 6.5)

electron domain In the VSEPR model, a region about a central atom in which an electron pair is concentrated. (Section 9.2)

electron-domain geometry The three-dimensional arrangement of the electron domains around an atom according to the VSEPR model. (Section 9.2)

electronegativity A measure of the ability of an atom that is bonded to another atom to attract electrons to itself. (Section 8.4)

electronic charge The negative charge carried by an electron; it has a magnitude of 1.602×10^{-19} C. (Section 2.3)

electronic structure The arrangement of electrons in an atom or molecule. (Chapter 6: Introduction)

electron-sea model A model for the behavior of electrons in metals. (Section 12.4)

electron shell A collection of orbitals that have the same value of n . For example, the orbitals with $n = 3$ (the $3s$, $3p$, and $3d$ orbitals) comprise the third shell. (Section 6.5)

electron spin A property of the electron that makes it behave as though it were a tiny magnet. The electron behaves as if it were spinning on its axis; electron spin is quantized. (Section 6.7)

element A substance consisting of atoms of the same atomic number. Historically defined as a substance that cannot be separated into simpler substances by chemical means. (Sections 1.1 and 1.2)

elemental semiconductor A semiconducting material composed of just one element. (Section 12.7)

elementary reaction A process in a chemical reaction that occurs in a single event or step. An

overall chemical reaction consists of one or more elementary reactions or steps. (Section 14.6)

empirical formula A chemical formula that shows the kinds of atoms and their relative numbers in a substance in the smallest possible whole-number ratios. (Section 2.6)

enantiomers Two mirror-image molecules of a chiral substance. The enantiomers are nonsuperimposable. (Section 23.4)

endothermic process A process in which a system absorbs heat from its surroundings. (Section 5.2)

energy The capacity to do work or to transfer heat. (Section 5.1)

energy-level diagram A diagram that shows the energies of molecular orbitals relative to the atomic orbitals from which they are derived. Also called a **molecular-orbital diagram**. (Section 9.7)

enthalpy A quantity defined by the relationship $H = E + PV$; the enthalpy change, ΔH , for a reaction that occurs at constant pressure is the heat evolved or absorbed in the reaction: $\Delta H = q_p$. (Section 5.3)

enthalpy of formation The enthalpy change that accompanies the formation of a substance from the most stable forms of its component elements. (Section 5.7)

enthalpy of reaction The enthalpy change associated with a chemical reaction. (Section 5.4)

entropy A thermodynamic function associated with the number of different equivalent energy states or spatial arrangements in which a system may be found. It is a thermodynamic state function, which means that once we specify the conditions for a system—that is, the temperature, pressure, and so on—the entropy is defined. (Section 19.2)

enzyme A protein molecule that acts to catalyze specific biochemical reactions. (Section 14.7)

equilibrium constant The numerical value of the equilibrium-constant expression for a system at equilibrium. The equilibrium constant is most usually denoted by K_p for gas-phase systems or K_c for solution-phase systems. (Section 15.2)

equilibrium-constant expression The expression that describes the relationship among the concentrations (or partial pressures) of the substances present in a system at equilibrium. The numerator is obtained by multiplying the concentrations of the substances on the product side of the equation, each raised to a power equal to its coefficient in the chemical equation. The denominator similarly contains the concentrations of the substances on the reactant side of the equation. (Section 15.2)

equivalence point The point in a titration at which the added solute reacts completely with the solute present in the solution. (Section 4.6)

ester An organic compound that has an OR group attached to a carbonyl; it is the product of a reaction between a carboxylic acid and an alcohol. (Section 24.4)

ether A compound in which two hydrocarbon groups are bonded to one oxygen. (Section 24.4)

exchange (metathesis) reaction A reaction between compounds that when written as a molecular equation appears to involve the exchange of ions between the two reactants. (Section 4.2)

excited state A higher energy state than the ground state. (Section 6.3)

exothermic process A process in which a system releases heat to its surroundings. (Section 5.2)

extensive property A property that depends on the amount of material considered; for example, mass or volume. (Section 1.3)

face-centered lattice A crystal lattice in which the lattice points are located at the faces and corners of each unit cell. (Section 12.2)

Faraday's constant (F) The magnitude of charge of one mole of electrons: 96,500 C/mol. (Section 20.5)

f-block metals Lanthanide and actinide elements in which the $4f$ or $5f$ orbitals are partially occupied. (Section 6.9)

ferrimagnetism A form of magnetism in which unpaired electron spins on different-type ions point in opposite directions but do not fully cancel out. (Section 23.1)

ferromagnetism A form of magnetism in which unpaired electron spins align parallel to one another. (Section 23.1)

first law of thermodynamics A statement that energy is conserved in any process. One way to express the law is that the change in internal energy, ΔE , of a system in any process is equal to the heat, q , added to the system, plus the work, w , done on the system by its surroundings: $\Delta E = q + w$. (Section 5.2)

first-order reaction A reaction in which the reaction rate is proportional to the concentration of a single reactant, raised to the first power. (Section 14.4)

fission The splitting of a large nucleus into two smaller ones. (Section 21.6)

foldings The process by which a protein adopts its biologically active shape. (Section 24.7)

force A push or a pull. (Section 5.1)

formal charge The number of valence electrons in an isolated atom minus the number of electrons assigned to the atom in the Lewis structure. (Section 8.5)

formation constant For a metal ion complex, the equilibrium constant for formation of the complex from the metal ion and base species present in solution. It is a measure of the tendency of the complex to form. (Section 17.5)

formula weight The mass of the collection of atoms represented by a chemical formula. For example, the formula weight of NO_2 (46.0 amu) is the sum of the masses of one nitrogen atom and two oxygen atoms. (Section 3.3)

fossil fuels Coal, oil, and natural gas, which are presently our major sources of energy. (Section 5.8)

free energy (Gibbs free energy, G) A thermodynamic state function that gives a criterion for spontaneous change in terms of enthalpy and entropy: $G = H - TS$. (Section 19.5)

free radical A substance with one or more unpaired electrons. (Section 21.9)

frequency The number of times per second that one complete wavelength passes a given point. (Section 6.1)

frequency factor (A) A term in the Arrhenius equation that is related to the frequency of collision and the probability that the collisions are favorably oriented for reaction. (Section 14.5)

fuel cell A voltaic cell that utilizes the oxidation of a conventional fuel, such as H_2 or CH_4 , in the cell reaction. (Section 20.7)

fuel value The energy released when 1 g of a substance is combusted. (Section 5.8)

functional group An atom or group of atoms that imparts characteristic chemical properties to an organic compound. (Section 24.1)

fusion The joining of two light nuclei to form a more massive one. (Section 21.6)

galvanic cell See **voltaic cell**. (Section 20.3)

gamma radiation Energetic electromagnetic radiation emanating from the nucleus of a radioactive atom. (Section 21.1)

gas Matter that has no fixed volume or shape; it conforms to the volume and shape of its container. (Section 1.2)

gas constant (R) The constant of proportionality in the ideal-gas equation. (Section 10.4)

geometric isomerism A form of isomerism in which compounds with the same type and number of atoms and the same chemical bonds have different spatial arrangements of these atoms and bonds. (Sections 23.4 and 24.4)

Gibbs free energy A thermodynamic state function that combines enthalpy and entropy, in the form $G = H - TS$. For a change occurring at constant temperature and pressure, the change in free energy is $\Delta G = \Delta H - T\Delta S$. (Section 19.5)

glass An amorphous solid formed by fusion of SiO_2 , CaO , and Na_2O . Other oxides may also be used to form glasses with differing characteristics. (Section 22.10)

glucose A polyhydroxy aldehyde whose formula is $\text{CH}_2\text{OH}(\text{CHOH})_4\text{CHO}$; it is the most important of the monosaccharides. (Section 24.8)

glycogen The general name given to a group of polysaccharides of glucose that are synthesized in mammals and used to store energy from carbohydrates. (Section 24.7)

Graham's law A law stating that the rate of effusion of a gas is inversely proportional to the square root of its molecular weight. (Section 10.8)

gray (Gy) The SI unit for radiation dose corresponding to the absorption of 1 J of energy per kilogram of biological material; 1 Gy = 100 rads. (Section 21.9)

green chemistry Chemistry that promotes the design and application of chemical products and processes that are compatible with human health and that preserve the environment. (Section 18.5)

greenhouse gases Gases in an atmosphere that absorb and emit infrared radiation (radiant heat), "trapping" heat in the atmosphere. (Section 18.2)

ground state The lowest-energy, or most stable, state. (Section 6.3)

group Elements that are in the same column of the periodic table; elements within the same group or family exhibit similarities in their chemical behavior. (Section 2.5)

Haber process The catalyst system and conditions of temperature and pressure developed by Fritz Haber and coworkers for the formation of NH_3 from H_2 and N_2 . (Section 15.2)

half-life The time required for the concentration of a reactant substance to decrease to half its initial value; the time required for half of a sample of a particular radioisotope to decay. (Sections 14.4 and 21.4)

half-reaction An equation for either an oxidation or a reduction that explicitly shows the electrons

involved, for example, $\text{Zn}^{2+}(\text{aq}) + 2\text{e}^- \longrightarrow \text{Zn}(\text{s})$. (Section 20.2)

Hall-Héroult process A process used to obtain aluminum by electrolysis of Al_2O_3 dissolved in molten cryolite, Na_3AlF_6 . (Section 20.9)

halogens Members of group 7A in the periodic table. (Section 7.8)

hard water Water that contains appreciable concentrations of Ca^{2+} and Mg^{2+} ; these ions react with soaps to form an insoluble material. (Section 18.4)

heat The flow of energy from a body at higher temperature to one at lower temperature when they are placed in thermal contact. (Section 5.1)

heat capacity The quantity of heat required to raise the temperature of a sample of matter by 1 °C (or 1 K). (Section 5.5)

heat of fusion The enthalpy change, ΔH , for melting a solid. (Section 11.4)

heat of sublimation The enthalpy change, ΔH , for vaporization of a solid. (Section 11.4)

heat of vaporization The enthalpy change, ΔH , for vaporization of a liquid. (Section 11.4)

Henderson-Hasselbalch equation The relationship among the pH, $\text{p}K_a$, and the concentrations of acid and conjugate base in an aqueous solution: $\text{pH} = \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]}$. (Section 17.2)

Henry's law A law stating that the concentration of a gas in a solution, S_g , is proportional to the pressure of gas over the solution: $S_g = kP_g$. (Section 13.3)

Hess's law The heat evolved in a given process can be expressed as the sum of the heats of several processes that, when added, yield the process of interest. (Section 5.6)

heterogeneous alloy An alloy in which the components are not distributed uniformly; instead, two or more distinct phases with characteristic compositions are present. (Section 12.3)

heterogeneous catalyst A catalyst that is in a different phase from that of the reactant substances. (Section 14.7)

heterogeneous equilibrium The equilibrium established between substances in two or more different phases, for example, between a gas and a solid or between a solid and a liquid. (Section 15.4)

hexagonal close packing A crystal structure where the atoms are packed together as closely as possible. The close-packed layers adopt a two-layer repeating pattern, which leads to a primitive hexagonal unit cell. (Section 12.3)

high-spin complex A complex whose electrons populate the d orbitals to give the maximum number of unpaired electrons. (Section 23.6)

hole A vacancy in the valence band of a semiconductor, created by doping. (Section 12.7)

homogeneous catalyst A catalyst that is in the same phase as the reactant substances. (Section 14.7)

homogeneous equilibrium The equilibrium established between reactant and product substances that are all in the same phase. (Section 15.4)

Hund's rule A rule stating that electrons occupy degenerate orbitals in such a way as to maximize the number of electrons with the same spin. In

other words, each orbital has one electron placed in it before pairing of electrons in orbitals occurs. (Section 6.8)

hybridization The mixing of different types of atomic orbitals to produce a set of equivalent hybrid orbitals. (Section 9.5)

hybrid orbital An orbital that results from the mixing of different kinds of atomic orbitals on the same atom. For example, an sp^3 hybrid results from the mixing, or hybridizing, of one s orbital and three p orbitals. (Section 9.5)

hydration Solvation when the solvent is water. (Section 13.1)

hydride ion An ion formed by the addition of an electron to a hydrogen atom: H^- . (Section 7.7)

hydrocarbons Compounds composed of only carbon and hydrogen. (Section 2.9)

hydrogen bonding Bonding that results from intermolecular attractions between molecules containing hydrogen bonded to an electronegative element. The most important examples involve OH , NH , and HF . (Section 11.2)

hydrolysis A reaction with water. When a cation or anion reacts with water, it changes the pH. (Sections 16.9 and 24.4)

hydronium ion (H_3O^+) The predominant form of the proton in aqueous solution. (Section 16.2)

hydrophilic Water attracting. The term is often used to describe a type of colloid. (Section 13.6)

hydrophobic Water repelling. The term is often used to describe a type of colloid. (Section 13.6)

hypothesis A tentative explanation of a series of observations or of a natural law. (Section 1.3)

ideal gas A hypothetical gas whose pressure, volume, and temperature behavior is completely described by the ideal-gas equation. (Section 10.4)

ideal-gas equation An equation of state for gases that embodies Boyle's law, Charles's law, and Avogadro's hypothesis in the form $PV = nRT$. (Section 10.4)

ideal solution A solution that obeys Raoult's law. (Section 13.5)

immiscible liquids Liquids that do not dissolve in one another to a significant extent. (Section 13.3)

indicator A substance added to a solution that changes color when the added solute has reacted with all the solute present in solution. The most common type of indicator is an acid–base indicator whose color changes as a function of pH. (Section 4.6)

instantaneous rate The reaction rate at a particular time as opposed to the average rate over an interval of time. (Section 14.2)

intensive property A property that is independent of the amount of material considered, for example, density. (Section 1.3)

interhalogens Compounds formed between two different halogen elements. Examples include IBr and BrF_3 . (Section 22.4)

intermediate A substance formed in one elementary step of a multistep mechanism and consumed in another; it is neither a reactant nor an ultimate product of the overall reaction. (Section 14.6)

intermetallic compound A homogeneous alloy with definite properties and a fixed composition. Intermetallic compounds are stoichiometric

compounds that form between metallic elements. (Section 12.3)

intermolecular forces The short-range attractive forces operating between the particles that make up the units of a liquid or solid substance. These same forces also cause gases to liquefy or solidify at low temperatures and high pressures. (Chapter 11: Introduction)

internal energy The total energy possessed by a system. When a system undergoes a change, the change in internal energy, ΔE , is defined as the heat, q , added to the system, plus the work, w , done on the system by its surroundings: $\Delta E = q + w$. (Section 5.2)

interstitial alloy An alloy in which smaller atoms fit into spaces between larger atoms. The larger atoms are metallic elements and the smaller atoms are typically nonmetallic elements. (Section 12.3)

ion Electrically charged atom or group of atoms (polyatomic ion); ions can be positively or negatively charged, depending on whether electrons are lost (positive) or gained (negative) by the atoms. (Section 2.7)

ion–dipole force The force that exists between an ion and a neutral polar molecule that possesses a permanent dipole moment. (Section 11.2)

ion exchange A process by which ions in solution are exchanged for other ions held on the surface of an ion-exchange resin; the exchange of a hard-water cation such as Ca^{2+} for a soft-water cation such as Na^+ is used to soften water. (Section 18.4)

ionic bond A bond between oppositely charged ions. The ions are formed from atoms by transfer of one or more electrons. (Section 8.1)

ionic compound A compound composed of cations and anions. (Section 2.7)

ionic hydrides Compounds formed when hydrogen reacts with alkali metals and also the heavier alkaline earths (Ca, Sr, and Ba); these compounds contain the hydride ion, H^- . (Section 22.2)

ionic solids Solids that are composed of ions. (Section 12.1)

ionization energy The energy required to remove an electron from a gaseous atom when the atom is in its ground state. (Section 7.4)

ionizing radiation Radiation that has sufficient energy to remove an electron from a molecule, thereby ionizing it. (Section 21.9)

ion-product constant For water, K_w is the product of the aquated hydrogen ion and hydroxide ion concentrations: $[H^+][OH^-] = K_w = 1.0 \times 10^{-14}$ at 25 °C. (Section 16.3)

irreversible process A process that cannot be reversed to restore both the system and its surroundings to their original states. Any spontaneous process is irreversible. (Section 19.1)

isoelectronic series A series of atoms, ions, or molecules having the same number of electrons. (Section 7.3)

isomers Compounds whose molecules have the same overall composition but different structures. (Sections 2.9 and 23.4)

isothermal process One that occurs at constant temperature. (Section 19.1)

isotopes Atoms of the same element containing different numbers of neutrons and therefore having different masses. (Section 2.3)

joule (J) The SI unit of energy, $1 \text{ kg}\cdot\text{m}^2/\text{s}^2$. A related unit is the calorie: $4.184 \text{ J} = 1 \text{ cal}$. (Section 5.1)

Kelvin scale The absolute temperature scale; the SI unit for temperature is the kelvin. Zero on the Kelvin scale corresponds to $-273.15 \text{ }^\circ\text{C}$. (Section 1.4)

ketone A compound in which the carbonyl group ($C=O$) occurs at the interior of a carbon chain and is therefore flanked by carbon atoms. (Section 24.4)

kinetic energy The energy that an object possesses by virtue of its motion. (Section 5.1)

kinetic-molecular theory A set of assumptions about the nature of gases. These assumptions, when translated into mathematical form, yield the ideal-gas equation. (Section 10.7)

lanthanide contraction The gradual decrease in atomic and ionic radii with increasing atomic number among the lanthanide elements, atomic numbers 57 through 70. The decrease arises because of a gradual increase in effective nuclear charge through the lanthanide series. (Section 23.1)

lanthanide (rare earth) element Element in which the $4f$ subshell is only partially occupied. (Sections 6.8 and 6.9)

lattice energy The energy required to separate completely the ions in an ionic solid. (Section 8.2)

lattice points Points in a crystal all of which have identical environments. (Section 12.2)

lattice vectors The vectors a , b , and c that define a crystal lattice. The position of any lattice point in a crystal can be represented by summing integer multiples of the lattice vectors. (Section 12.2)

law of constant composition A law that states that the elemental composition of a pure compound is always the same, regardless of its source; also called the **law of definite proportions**. (Section 1.2)

law of definite proportions A law that states that the elemental composition of a pure substance is always the same, regardless of its source; also called the **law of constant composition**. (Section 1.2)

law of mass action The rules by which the equilibrium constant is expressed in terms of the concentrations of reactants and products, in accordance with the balanced chemical equation for the reaction. (Section 15.2)

Le Châtelier's principle A principle stating that when we disturb a system at chemical equilibrium, the relative concentrations of reactants and products shift so as to partially undo the effects of the disturbance. (Section 15.7)

levorotatory, or merely levo or / A term used to label a chiral molecule that rotates the plane of polarization of plane-polarized light to the left (counterclockwise). (Section 24.4)

Lewis acid An electron-pair acceptor. (Section 16.11)

Lewis base An electron-pair donor. (Section 16.11)

Lewis structure A representation of covalent bonding in a molecule that is drawn using Lewis symbols. Shared electron pairs are shown as lines, and unshared electron pairs are shown as pairs of dots. Only the valence-shell electrons are shown. (Section 8.3)

Lewis symbol (electron-dot symbol) The chemical symbol for an element, with a dot for each valence electron. (Section 8.1)

ligand An ion or molecule that coordinates to a metal atom or to a metal ion to form a complex. (Section 23.2)

lime-soda process A method used in large-scale water treatment to reduce water hardness by removing Mg^{2+} and Ca^{2+} . The substances added to the water are lime, CaO [or slaked lime, $Ca(OH)_2$], and soda ash, Na_2CO_3 , in amounts determined by the concentrations of the undesired ions. (Section 18.4)

limiting reactant (limiting reagent) The reactant present in the smallest stoichiometric quantity in a mixture of reactants; the amount of product that can form is limited by the complete consumption of the limiting reactant. (Section 3.7)

line spectrum A spectrum that contains radiation at only certain specific wavelengths. (Section 6.3)

linkage isomers Structural isomers of coordination compounds in which a ligand differs in its mode of attachment to a metal ion. (Section 23.4)

lipid A nonpolar molecule derived from glycerol and fatty acids that is used by organisms for long-term energy storage. (Section 24.9)

liquid Matter that has a distinct volume but no specific shape. (Section 1.2)

liquid crystal A substance that exhibits one or more partially ordered liquid phases above the melting point of the solid form. By contrast, in nonliquid crystalline substances the liquid phase that forms upon melting is completely unordered. (Section 11.7)

lock-and-key model A model of enzyme action in which the substrate molecule is pictured as fitting rather specifically into the active site on the enzyme. It is assumed that in being bound to the active site, the substrate is somehow activated for reaction. (Section 14.7)

low-spin complex A metal complex in which the electrons are paired in lower-energy orbitals. (Section 23.6)

magic numbers Numbers of protons and neutrons that result in very stable nuclei. (Section 21.2)

main-group elements Elements in the *s* and *p* blocks of the periodic table. (Section 6.9)

mass A measure of the amount of material in an object. It measures the resistance of an object to being moved. In SI units, mass is measured in kilograms. (Section 1.4)

mass defect The difference between the mass of a nucleus and the total masses of the individual nucleons that it contains. (Section 21.6)

mass number The sum of the number of protons and neutrons in the nucleus of a particular atom. (Section 2.3)

mass percentage The number of grams of solute in each 100 g of solution. (Section 13.4)

mass spectrometer An instrument used to measure the precise masses and relative amounts of atomic and molecular ions. (Section 2.4)

matter Anything that occupies space and has mass; the physical material of the universe. (Section 1.1)

matter waves The term used to describe the wave characteristics of a moving particle. (Section 6.4)

mean free path The average distance traveled by a gas molecule between collisions. (Section 10.8)

metal complex An assembly of a metal ion and the Lewis bases bonded to it. (Section 23.2)

metallic bond Bonding, usually in solid metals, in which the bonding electrons are relatively free to move throughout the three-dimensional structure. (Section 8.1)

metallic character The extent to which an element exhibits the physical and chemical properties characteristic of metals, for example, luster, malleability, ductility, and good thermal and electrical conductivity. (Section 7.6)

metallic elements (metals) Elements that are usually solids at room temperature, exhibit high electrical and heat conductivity, and appear lustrous. Most of the elements in the periodic table are metals. (Sections 2.5 and 12.1)

metallic hydrides Compounds formed when hydrogen reacts with transition metals; these compounds contain the hydride ion, H^- . (Section 22.2)

metallic solids Solids that are composed of metal atoms. (Section 12.1)

metalloids Elements that lie along the diagonal line separating the metals from the nonmetals in the periodic table; the properties of metalloids are intermediate between those of metals and nonmetals. (Section 2.5)

metallurgy The science of extracting metals from their natural sources by a combination of chemical and physical processes. It is also concerned with the properties and structures of metals and alloys. (Section 23.1)

metathesis (exchange) reaction A reaction in which two substances react through an exchange of their component ions: $AX + BY \longrightarrow AY + BX$. Precipitation and acid-base neutralization reactions are examples of metathesis reactions. (Section 4.2)

metric system A system of measurement used in science and in most countries. The meter and the gram are examples of metric units. (Section 1.4)

microstate The state of a system at a particular instant; one of many possible energetically equivalent ways to arrange the components of a system to achieve a particular state. (Section 19.3)

mineral A solid, inorganic substance occurring in nature, such as calcium carbonate, which occurs as calcite. (Section 23.1)

miscible liquids Liquids that mix in all proportions. (Section 13.3)

mixture A combination of two or more substances in which each substance retains its own chemical identity. (Section 1.2)

molal boiling-point-elevation constant (K_b) A constant characteristic of a particular solvent that gives the increase in boiling point as a function of solution molality: $\Delta T_b = K_b m$. (Section 13.5)

molal freezing-point-depression constant (K_f) A constant characteristic of a particular solvent that gives the decrease in freezing point as a function of solution molality: $\Delta T_f = K_f m$. (Section 13.5)

molality The concentration of a solution expressed as moles of solute per kilogram of solvent; abbreviated *m*. (Section 13.4)

molar heat capacity The heat required to raise the temperature of one mole of a substance by 1 °C. (Section 5.5)

molarity The concentration of a solution expressed as moles of solute per liter of solution; abbreviated *M*. (Section 4.5)

molar mass The mass of one mole of a substance in grams; it is numerically equal to the formula weight in atomic mass units. (Section 3.4)

mole A collection of Avogadro's number (6.022×10^{23}) of objects; for example, a mole of H_2O is 6.022×10^{23} H_2O molecules. (Section 3.4)

molecular compound A compound that consists of molecules. (Section 2.6)

molecular equation A chemical equation in which the formula for each substance is written without regard for whether it is an electrolyte or a nonelectrolyte. (Section 4.2)

molecular formula A chemical formula that indicates the actual number of atoms of each element in one molecule of a substance. (Section 2.6)

molecular geometry The arrangement in space of the atoms of a molecule. (Section 9.2)

molecular hydrides Compounds formed when hydrogen reacts with nonmetals and metalloids. (Section 22.2)

molecularity The number of molecules that participate as reactants in an elementary reaction. (Section 14.6)

molecular orbital (MO) An allowed state for an electron in a molecule. According to molecular-orbital theory, a molecular orbital is entirely analogous to an atomic orbital, which is an allowed state for an electron in an atom. Most bonding molecular orbitals can be classified as σ or π , depending on the disposition of electron density with respect to the internuclear axis. (Section 9.7)

molecular-orbital diagram A diagram that shows the energies of molecular orbitals relative to the atomic orbitals from which they are derived; also called an **energy-level diagram**. (Section 9.7)

molecular-orbital theory A theory that accounts for the allowed states for electrons in molecules. (Section 9.7)

molecular solids Solids that are composed of molecules. (Sections 12.1 and 12.6)

molecular weight The mass of the collection of atoms represented by the chemical formula for a molecule. (Section 3.3)

molecule A chemical combination of two or more atoms. (Sections 1.1 and 2.6)

mole fraction The ratio of the number of moles of one component of a mixture to the total moles of all components; abbreviated *X*, with a subscript to identify the component. (Section 10.6)

momentum The product of the mass, *m*, and velocity, *v*, of an object. (Section 6.4)

monodentate ligand A ligand that binds to the metal ion via a single donor atom. It occupies one position in the coordination sphere. (Section 23.3)

monomers Molecules with low molecular weights, which can be joined together (polymerized) to form a polymer. (Section 12.8)

monosaccharide A simple sugar, most commonly containing six carbon atoms. The joining together of monosaccharide units by condensation

reactions results in formation of polysaccharides. (Section 24.8)

nanomaterial A solid whose dimensions range from 1 to 100 nm and whose properties differ from those of a bulk material with the same composition. (Section 12.1)

natural gas A naturally occurring mixture of gaseous hydrocarbon compounds composed of hydrogen and carbon. (Section 5.8)

nematic liquid crystalline phase A liquid crystal in which the molecules are aligned in the same general direction, along their long axes, but in which the ends of the molecules are not aligned. (Section 11.7)

Nernst equation An equation that relates the cell emf, E , to the standard emf, E° , and the reaction quotient, Q : $E = E^\circ - (RT/nF) \ln Q$. (Section 20.6)

net ionic equation A chemical equation for a solution reaction in which soluble strong electrolytes are written as ions and spectator ions are omitted. (Section 4.2)

neutralization reaction A reaction in which an acid and a base react in stoichiometrically equivalent amounts; the neutralization reaction between an acid and a metal hydroxide produces water and a salt. (Section 4.3)

neutron An electrically neutral particle found in the nucleus of an atom; it has approximately the same mass as a proton. (Section 2.3)

noble gases Members of group 8A in the periodic table. (Section 7.8)

node Points in an atom at which the electron density is zero. For example, the node in a $2s$ orbital is a spherical surface. (Section 6.6)

nonbonding pair In a Lewis structure a pair of electrons assigned completely to one atom; also called a lone pair. (Section 9.2)

nonelectrolyte A substance that does not ionize in water and consequently gives a nonconducting solution. (Section 4.1)

nonionizing radiation Radiation that does not have sufficient energy to remove an electron from a molecule. (Section 21.9)

nonmetallic elements (nonmetals) Elements in the upper right corner of the periodic table; nonmetals differ from metals in their physical and chemical properties. (Section 2.5)

nonpolar covalent bond A covalent bond in which the electrons are shared equally. (Section 8.4)

normal boiling point The boiling point at 1 atm pressure. (Section 11.5)

normal melting point The melting point at 1 atm pressure. (Section 11.6)

nuclear binding energy The energy required to decompose an atomic nucleus into its component protons and neutrons. (Section 21.6)

nuclear disintegration series A series of nuclear reactions that begins with an unstable nucleus and terminates with a stable one; also called a **radioactive series**. (Section 21.2)

nuclear model Model of the atom with a nucleus containing protons and neutrons and with electrons in the space outside the nucleus. (Section 2.2)

nuclear transmutation A conversion of one kind of nucleus to another. (Section 21.3)

nucleic acids Polymers of high molecular weight that carry genetic information and control protein synthesis. (Section 24.10)

nucleon A particle found in the nucleus of an atom. (Section 21.1)

nucleotide Compounds formed from a molecule of phosphoric acid, a sugar molecule, and an organic nitrogen base. Nucleotides form linear polymers called DNA and RNA, which are involved in protein synthesis and cell reproduction. (Section 24.10)

nucleus The very small, very dense, positively charged portion of an atom; it is composed of protons and neutrons. (Section 2.2)

octet rule A rule stating that bonded atoms tend to possess or share a total of eight valence-shell electrons. (Section 8.1)

optical isomerism A form of isomerism in which the two forms of a compound (stereoisomers) are nonsuperimposable mirror images. (Section 23.4)

optically active Possessing the ability to rotate the plane of polarized light. (Section 23.4)

orbital An allowed energy state of an electron in the quantum mechanical model of the atom; the term *orbital* is also used to describe the spatial distribution of the electron. An orbital is defined by the values of three quantum numbers: n , l , and m_l (Section 6.5)

organic chemistry The study of carbon-containing compounds, typically containing carbon-carbon bonds. (Section 2.9; Chapter 24: Introduction)

osmosis The net movement of solvent through a semipermeable membrane toward the solution with greater solute concentration. (Section 13.5)

osmotic pressure The pressure that must be applied to a solution to stop osmosis from pure solvent into the solution. (Section 13.5)

Ostwald process An industrial process used to make nitric acid from ammonia. The NH_3 is catalytically oxidized by O_2 to form NO ; NO in air is oxidized to NO_2 ; HNO_3 is formed in a disproportionation reaction when NO_2 dissolves in water. (Section 22.7)

overall reaction order The sum of the reaction orders of all the reactants appearing in the rate expression when the rate can be expressed as rate = $k[\text{A}]^a[\text{B}]^b \dots$ (Section 14.3)

overlap The extent to which atomic orbitals on different atoms share the same region of space. When the overlap between two orbitals is large, a strong bond may be formed. (Section 9.4)

oxidation A process in which a substance loses one or more electrons. (Section 4.4)

oxidation number (oxidation state) A positive or negative whole number assigned to an element in a molecule or ion on the basis of a set of formal rules; to some degree it reflects the positive or negative character of that atom. (Section 4.4)

oxidation-reduction (redox) reaction A chemical reaction in which the oxidation states of certain atoms change. (Section 4.4; Chapter 20: Introduction)

oxidizing agent, or oxidant The substance that is reduced and thereby causes the oxidation of some other substance in an oxidation-reduction reaction. (Section 20.1)

oxyacid A compound in which one or more OH groups, and possibly additional oxygen atoms, are bonded to a central atom. (Section 16.10)

oxyanion A polyatomic anion that contains one or more oxygen atoms. (Section 2.8)

ozone The name given to O_3 , an allotrope of oxygen. (Section 7.8)

paramagnetism A property that a substance possesses if it contains one or more unpaired electrons. A paramagnetic substance is drawn into a magnetic field. (Section 9.8)

partial pressure The pressure exerted by a particular gas in a mixture. (Section 10.6)

particle accelerator A device that uses strong magnetic and electrostatic fields to accelerate charged particles. (Section 21.3)

parts per billion (ppb) The concentration of a solution in grams of solute per 10^9 (billion) grams of solution; equals micrograms of solute per liter of solution for aqueous solutions. (Section 13.4)

parts per million (ppm) The concentration of a solution in grams of solute per 10^6 (million) grams of solution; equals milligrams of solute per liter of solution for aqueous solutions. (Section 13.4)

pascal (Pa) The SI unit of pressure: $1 \text{ Pa} = 1 \text{ N/m}^2$. (Section 10.2)

Pauli exclusion principle A rule stating that no two electrons in an atom may have the same four quantum numbers (n , l , m_l , and m_s). As a reflection of this principle, there can be no more than two electrons in any one atomic orbital. (Section 6.7)

peptide bond A bond formed between two amino acids. (Section 24.7)

percent ionization The percent of a substance that undergoes ionization on dissolution in water. The term applies to solutions of weak acids and bases. (Section 16.6)

percent yield The ratio of the actual (experimental) yield of a product to its theoretical (calculated) yield, multiplied by 100. (Section 3.7)

period The row of elements that lie in a horizontal row in the periodic table. (Section 2.5)

periodic table The arrangement of elements in order of increasing atomic number, with elements having similar properties placed in vertical columns. (Section 2.5)

petroleum A naturally occurring combustible liquid composed of hundreds of hydrocarbons and other organic compounds. (Section 5.8)

pH The negative log in base 10 of the aquated hydrogen ion concentration: $\text{pH} = -\log[\text{H}^+]$. (Section 16.4)

pH titration curve A graph of pH as a function of added titrant. (Section 17.3)

phase change The conversion of a substance from one state of matter to another. The phase changes we consider are melting and freezing (solid \rightleftharpoons liquid), sublimation and deposition, and vaporization and condensation (liquid \rightleftharpoons gas). (Section 11.4)

phase diagram A graphic representation of the equilibria among the solid, liquid, and gaseous phases of a substance as a function of temperature and pressure. (Section 11.6)

phospholipid A form of lipid molecule that contains charged phosphate groups. (Section 24.9)

photochemical smog A complex mixture of undesirable substances produced by the action of sunlight on an urban atmosphere polluted with automobile emissions. The major starting ingredients are nitrogen oxides and organic substances, notably olefins and aldehydes. (Section 18.2)

photodissociation The breaking of a molecule into two or more neutral fragments as a result of absorption of light. (Section 18.2)

photoelectric effect The emission of electrons from a metal surface induced by light. (Section 6.2)

photoionization The removal of an electron from an atom or molecule by absorption of light. (Section 18.2)

photon The smallest increment (a quantum) of radiant energy; a photon of light with frequency ν has an energy equal to $h\nu$. (Section 6.2)

photosynthesis The process that occurs in plant leaves by which light energy is used to convert carbon dioxide and water to carbohydrates and oxygen. (Section 23.3)

physical changes Changes (such as a phase change) that occur with no change in chemical composition. (Section 1.3)

physical properties Properties that can be measured without changing the composition of a substance, for example, color and freezing point. (Section 1.3)

pi (π) bond A covalent bond in which electron density is concentrated above and below the internuclear axis. (Section 9.6)

pi (π) molecular orbital A molecular orbital that concentrates the electron density on opposite sides of an imaginary line that passes through the nuclei. (Section 9.8)

Planck's constant (h) The constant that relates the energy and frequency of a photon, $E = h\nu$. Its value is 6.626×10^{-34} J·s. (Section 6.2)

plastic A material that can be formed into particular shapes by application of heat and pressure. (Section 12.8)

polar covalent bond A covalent bond in which the electrons are not shared equally. (Section 8.4)

polarizability The ease with which the electron cloud of an atom or a molecule is distorted by an outside influence, thereby inducing a dipole moment. (Section 11.2)

polar molecule A molecule that possesses a nonzero dipole moment. (Section 8.4)

polyatomic ion An electrically charged group of two or more atoms. (Section 2.7)

polydentate ligand A ligand in which two or more donor atoms can coordinate to the same metal ion. (Section 23.3)

polymer A large molecule of high molecular mass, formed by the joining together, or polymerization, of a large number of molecules of low molecular mass. The individual molecules forming the polymer are called monomers. (Sections 12.1 and 12.8)

polypeptide A polymer of amino acids that has a molecular weight of less than 10,000. (Section 24.7)

polyprotic acid A substance capable of dissociating more than one proton in water; H_2SO_4 is an example. (Section 16.6)

polysaccharide A substance made up of many monosaccharide units joined together. (Section 24.8)

porphyrin A complex derived from the porphine molecule. (Section 23.3)

positron emission A nuclear decay process where a positron, a particle with the same mass as an electron but with a positive charge, symbol ${}^0_1\text{e}$, is emitted from the nucleus. (Section 21.1)

potential energy The energy that an object possesses as a result of its composition or its position with respect to another object. (Section 5.1)

precipitate An insoluble substance that forms in, and separates from, a solution. (Section 4.2)

precipitation reaction A reaction that occurs between substances in solution in which one of the products is insoluble. (Section 4.2)

precision The closeness of agreement among several measurements of the same quantity; the reproducibility of a measurement. (Section 1.5)

pressure A measure of the force exerted on a unit area. In chemistry, pressure is often expressed in units of atmospheres (atm) or torr: 760 torr = 1 atm; in SI units pressure is expressed in pascals (Pa). (Section 10.2)

pressure-volume (PV) work Work performed by expansion of a gas against a resisting pressure. (Section 5.3)

primary structure The sequence of amino acids along a protein chain. (Section 24.7)

primitive lattice A crystal lattice in which the lattice points are located only at the corners of each unit cell. (Section 12.2)

probability density (ψ^2) A value that represents the probability that an electron will be found at a given point in space. Also called **electron density**. (Section 6.5)

product A substance produced in a chemical reaction; it appears to the right of the arrow in a chemical equation. (Section 3.1)

property A characteristic that gives a sample of matter its unique identity. (Section 1.1)

protein A biopolymer formed from amino acids. (Section 24.7)

protium The most common isotope of hydrogen. (Section 22.2)

proton A positively charged subatomic particle found in the nucleus of an atom. (Section 2.3)

pure substance Matter that has a fixed composition and distinct properties. (Section 1.2)

pyrometallurgy A process in which heat converts a mineral in an ore from one chemical form to another and eventually to the free metal. (Section 23.2)

qualitative analysis The determination of the presence or absence of a particular substance in a mixture. (Section 17.7)

quantitative analysis The determination of the amount of a given substance that is present in a sample. (Section 17.7)

quantum The smallest increment of radiant energy that may be absorbed or emitted; the magnitude of radiant energy is $h\nu$. (Section 6.2)

quaternary structure The structure of a protein resulting from the clustering of several individual protein chains into a final specific shape. (Section 24.7)

racemic mixture A mixture of equal amounts of the dextrorotatory and levorotatory forms of a chiral molecule. A racemic mixture will not rotate the plane of polarized light. (Section 23.4)

rad A measure of the energy absorbed from radiation by tissue or other biological material; 1 rad = transfer of 1×10^{-2} J of energy per kilogram of material. (Section 21.9)

radial probability function The probability that the electron will be found at a certain distance from the nucleus. (Section 6.6)

radioactive Possessing **radioactivity**, the spontaneous disintegration of an unstable atomic nucleus with accompanying emission of radiation. (Section 2.2; Chapter 21: Introduction)

radioactive series A series of nuclear reactions that begins with an unstable nucleus and terminates with a stable one. Also called **nuclear disintegration series**. (Section 21.2)

radioisotope An isotope that is radioactive; that is, it is undergoing nuclear changes with emission of radiation. (Section 21.1)

radionuclide A radioactive nuclide. (Section 21.1)

radiotracer A radioisotope that can be used to trace the path of an element in a chemical system. (Section 21.5)

Raoult's law A law stating that the partial pressure of a solvent over a solution, P_{solution} , is given by the vapor pressure of the pure solvent, $P_{\text{solvent}}^{\circ}$, times the mole fraction of a solvent in the solution, X_{solvent} : $P_{\text{solution}} = X_{\text{solvent}} P_{\text{solvent}}^{\circ}$. (Section 13.5)

rare earth element See **lanthanide element**. (Sections 6.8 and 6.9)

rate constant A constant of proportionality between the reaction rate and the concentrations of reactants that appear in the rate law. (Section 14.3)

rate-determining step The slowest elementary step in a reaction mechanism. (Section 14.6)

rate law An equation that relates the reaction rate to the concentrations of reactants (and sometimes of products also). (Section 14.3)

reactant A starting substance in a chemical reaction; it appears to the left of the arrow in a chemical equation. (Section 3.1)

reaction mechanism A detailed picture, or model, of how the reaction occurs; that is, the order in which bonds are broken and formed and the changes in relative positions of the atoms as the reaction proceeds. (Section 14.6)

reaction order The power to which the concentration of a reactant is raised in a rate law. (Section 14.3)

reaction quotient (Q) The value that is obtained when concentrations of reactants and products are inserted into the equilibrium expression. If the concentrations are equilibrium concentrations, $Q = K$; otherwise, $Q \neq K$. (Section 15.6)

reaction rate A measure of the decrease in concentration of a reactant or the increase in concentration of a product with time. (Section 14.2)

redox (oxidation-reduction) reaction A reaction in which certain atoms undergo changes in oxidation states. The substance increasing in oxidation state is oxidized; the substance decreasing in oxidation state is reduced. (Section 4.4; Chapter 20: Introduction)

reducing agent, or reductant The substance that is oxidized and thereby causes the reduction of

some other substance in an oxidation-reduction reaction. (Section 20.1)

reduction A process in which a substance gains one or more electrons. (Section 4.4)

rem A measure of the biological damage caused by radiation; $\text{rems} = \text{rads} \times \text{RBE}$. (Section 21.9)

renewable energy sources Energy such as solar energy, wind energy, and hydroelectric energy derived from essentially inexhaustible sources. (Section 5.8)

representative (main-group) element An element from within the *s* and *p* blocks of the periodic table (Figure 6.29). (Section 6.9)

resonance structures (resonance forms) Individual Lewis structures in cases where two or more Lewis structures are equally good descriptions of a single molecule. The resonance structures in such an instance are “averaged” to give a more accurate description of the real molecule. (Section 8.6)

reverse osmosis The process by which water molecules move under high pressure through a semi-permeable membrane from the more concentrated to the less concentrated solution. (Section 18.4)

reversible process A process that can go back and forth between states along exactly the same path; a system at equilibrium is reversible if equilibrium can be shifted by an infinitesimal modification of a variable such as temperature. (Section 19.1)

ribonucleic acid (RNA) A polynucleotide in which ribose is the sugar component. (Section 24.10)

root-mean-square (rms) speed (μ) The square root of the average of the squared speeds of the gas molecules in a gas sample. (Section 10.7)

rotational motion Movement of a molecule as though it is spinning like a top. (Section 19.3)

salinity A measure of the salt content of seawater, brine, or brackish water. It is equal to the mass in grams of dissolved salts present in 1 kg of seawater. (Section 18.3)

salt An ionic compound formed by replacing one or more hydrogens of an acid by other cations. (Section 4.3)

saponification Hydrolysis of an ester in the presence of a base. (Section 24.4)

saturated solution A solution in which undissolved solute and dissolved solute are in equilibrium. (Section 13.2)

scientific law A concise verbal statement or a mathematical equation that summarizes a wide range of observations and experiences. (Section 1.3)

scientific method The general process of advancing scientific knowledge by making experimental observations and by formulating hypotheses, theories, and laws. (Section 1.3)

secondary structure The manner in which a protein is coiled or stretched. (Section 24.7)

second law of thermodynamics A statement of our experience that there is a direction to the way events occur in nature. When a process occurs spontaneously in one direction, it is nonspontaneous in the reverse direction. It is possible to state the second law in many different forms, but they all relate back to the same idea about spontaneity. One of the most common statements found in chemical contexts is that in any spontaneous process the entropy of the universe increases. (Section 19.2)

second-order reaction A reaction in which the overall reaction order (the sum of the concentration-term exponents) in the rate law is 2. (Section 14.4)

sigma (σ) bond A covalent bond in which electron density is concentrated along the internuclear axis. (Section 9.6)

sigma (σ) molecular orbital A molecular orbital that centers the electron density about an imaginary line passing through two nuclei. (Section 9.7)

significant figures The digits that indicate the precision with which a measurement is made; all digits of a measured quantity are significant, including the last digit, which is uncertain. (Section 1.5)

silica Common name for silicon dioxide. (Section 22.4)

silicates Compounds containing silicon and oxygen, structurally based on SiO_4 tetrahedra. (Section 22.10)

single bond A covalent bond involving one electron pair. (Section 8.3)

SI units The preferred metric units for use in science. (Section 1.4)

smectic liquid crystalline phase A liquid crystal in which the molecules are aligned along their long axes and arranged in sheets, with the ends of the molecules aligned. There are several different kinds of smectic phases. (Section 12.8)

solid Matter that has both a definite shape and a definite volume. (Section 1.2)

solubility The amount of a substance that dissolves in a given quantity of solvent at a given temperature to form a saturated solution. (Sections 4.2 and 13.2)

solubility-product constant (solubility product) (K_{sp}) An equilibrium constant related to the equilibrium between a solid salt and its ions in solution. It provides a quantitative measure of the solubility of a slightly soluble salt. (Section 17.4)

solute A substance dissolved in a solvent to form a solution; it is normally the component of a solution present in the smaller amount. (Section 4.1)

solution A mixture of substances that has a uniform composition; a homogeneous mixture. (Section 1.2)

solution alloy A homogeneous alloy, where two or more elements are distributed randomly and uniformly throughout the solid. (Section 12.3)

solvation The clustering of solvent molecules around a solute particle. (Section 13.1)

solvent The dissolving medium of a solution; it is normally the component of a solution present in the greater amount. (Section 4.1)

specific heat (C_s) The heat capacity of 1 g of a substance; the heat required to raise the temperature of 1 g of a substance by 1 °C. (Section 5.5)

spectator ions Ions that go through a reaction unchanged and that appear on both sides of the complete ionic equation. (Section 4.2)

spectrochemical series A list of ligands arranged in order of their abilities to split the *d*-orbital energies (using the terminology of the crystal-field model). (Section 23.6)

spectrum The distribution among various wavelengths of the radiant energy emitted or absorbed by an object. (Section 6.3)

spin magnetic quantum number (m_s) A quantum number associated with the electron spin; it may have values of $+\frac{1}{2}$ or $-\frac{1}{2}$. (Section 6.7)

spin-pairing energy The energy required to pair an electron with another electron occupying an orbital. (Section 23.6)

spontaneous process A process that is capable of proceeding in a given direction, as written or described, without needing to be driven by an outside source of energy. A process may be spontaneous even though it is very slow. (Section 19.1)

standard atmospheric pressure Defined as 760 torr or, in SI units, 101.325 kPa. (Section 10.2)

standard emf, also called the standard cell potential (E°) The emf of a cell when all reagents are at standard conditions. (Section 20.4)

standard enthalpy change (ΔH°) The change in enthalpy in a process when all reactants and products are in their stable forms at 1 atm pressure and a specified temperature, commonly 25 °C. (Section 5.7)

standard enthalpy of formation (ΔH_f°) The change in enthalpy that accompanies the formation of one mole of a substance from its elements, with all substances in their standard states. (Section 5.7)

standard free energy of formation (ΔG_f°) The change in free energy associated with the formation of a substance from its elements under standard conditions. (Section 19.5)

standard hydrogen electrode (SHE) An electrode based on the half-reaction $2\text{H}^+(1\text{ M}) + 2\text{e}^- \longrightarrow \text{H}_2(1\text{ atm})$. The standard electrode potential of the standard hydrogen electrode is defined as 0 V. (Section 20.4)

standard molar entropy (S°) The entropy value for a mole of a substance in its standard state. (Section 19.4)

standard reduction potential (E_{red}°) The potential of a reduction half-reaction under standard conditions, measured relative to the standard hydrogen electrode. A standard reduction potential is also called a **standard electrode potential**. (Section 20.4)

standard solution A solution of known concentration. (Section 4.6)

standard temperature and pressure (STP) Defined as 0 °C and 1 atm pressure; frequently used as reference conditions for a gas. (Section 10.4)

starch The general name given to a group of polysaccharides that acts as energy-storage substances in plants. (Section 24.8)

state function A property of a system that is determined by its state or condition and not by how it got to that state; its value is fixed when temperature, pressure, composition, and physical form are specified; *P*, *V*, *T*, *E*, and *H* are state functions. (Section 5.2)

states of matter The three forms that matter can assume: solid, liquid, and gas. (Section 1.2)

stereoisomers Compounds possessing the same formula and bonding arrangement but differing in the spatial arrangements of the atoms. (Section 23.4)

stoichiometry The relationships among the quantities of reactants and products involved in chemical reactions. (Chapter 3: Introduction)

stratosphere The region of the atmosphere directly above the troposphere. (Section 18.1)

strong acid An acid that ionizes completely in water. (Section 4.3)

strong base A base that ionizes completely in water. (Section 4.3)

strong electrolyte A substance (strong acids, strong bases, and most salts) that is completely ionized in solution. (Section 4.1)

structural formula A formula that shows not only the number and kinds of atoms in the molecule but also the arrangement (connections) of the atoms. (Section 2.6)

structural isomers Compounds possessing the same formula but differing in the bonding arrangements of the atoms. (Sections 23.4 and 24.2)

subatomic particles Particles such as protons, neutrons, and electrons that are smaller than an atom. (Section 2.2)

subshell One or more orbitals with the same set of quantum numbers n and l . For example, we speak of the $2p$ subshell ($n = 2, l = 1$), which is composed of three orbitals ($2p_x, 2p_y,$ and $2p_z$). (Section 6.5)

substitutional alloy A homogeneous (solution) alloy in which atoms of different elements randomly occupy sites in the lattice. (Section 23.6)

substitution reactions Reactions in which one atom (or group of atoms) replaces another atom (or group) within a molecule; substitution reactions are typical for alkanes and aromatic hydrocarbons. (Section 24.3)

substrate A substance that undergoes a reaction at the active site in an enzyme. (Section 14.7)

supercritical mass An amount of fissionable material larger than the critical mass. (Section 21.7)

supersaturated solution A solution containing more solute than an equivalent saturated solution. (Section 13.2)

surface tension The intermolecular, cohesive attraction that causes a liquid to minimize its surface area. (Section 11.3)

surroundings In thermodynamics, everything that lies outside the system that we study. (Section 5.1)

system In thermodynamics, the portion of the universe that we single out for study. We must be careful to state exactly what the system contains and what transfers of energy it may have with its surroundings. (Section 5.1)

termolecular reaction An elementary reaction that involves three molecules. Termolecular reactions are rare. (Section 14.6)

tertiary structure The overall shape of a large protein, specifically, the manner in which sections of the protein fold back upon themselves or intertwine. (Section 24.7)

theoretical yield The quantity of product that is calculated to form when all of the limiting reagent reacts. (Section 3.7)

theory A tested model or explanation that satisfactorily accounts for a certain set of phenomena. (Section 1.3)

thermochemistry The relationship between chemical reactions and energy changes. (Chapter 5: Introduction)

thermodynamics The study of energy and its transformation. (Chapter 5: Introduction)

thermonuclear reaction Another name for fusion reactions; reactions in which two light nuclei are joined to form a more massive one. (Section 21.8)

thermoplastic A polymeric material that can be readily reshaped by application of heat and pressure. (Section 12.8)

thermosetting plastic A plastic that, once formed in a particular mold, is not readily reshaped by application of heat and pressure. (Section 12.8)

third law of thermodynamics A law stating that the entropy of a pure, crystalline solid at absolute zero temperature is zero: $S(0\text{ K}) = 0$. (Section 19.3)

titration The process of reacting a solution of unknown concentration with one of known concentration (a standard solution). (Section 4.6)

torr A unit of pressure ($1\text{ torr} = 1\text{ mm Hg}$). (Section 10.2)

transition elements (transition metals) Elements in which the d orbitals are partially occupied. (Section 6.8)

transition state (activated complex) The particular arrangement of reactant and product molecules at the point of maximum energy in the rate-determining step of a reaction. (Section 14.5)

translational motion Movement in which an entire molecule moves in a definite direction. (Section 19.3)

transuranium elements Elements that follow uranium in the periodic table. (Section 21.3)

triple bond A covalent bond involving three electron pairs. (Section 8.3)

triple point The temperature at which solid, liquid, and gas phases coexist in equilibrium. (Section 11.6)

tritium The isotope of hydrogen whose nucleus contains a proton and two neutrons. (Section 22.2)

troposphere The region of Earth's atmosphere extending from the surface to about 12 km altitude. (Section 18.1)

Tyndall effect The scattering of a beam of visible light by the particles in a colloidal dispersion. (Section 13.6)

uncertainty principle A principle stating there is an inherent uncertainty in the precision with which we can simultaneously specify the position and momentum of a particle. This uncertainty is significant only for particles of extremely small mass, such as electrons. (Section 6.4)

unimolecular reaction An elementary reaction that involves a single molecule. (Section 14.6)

unit cell The smallest portion of a crystal that reproduces the structure of the entire crystal when repeated in different directions in space. It is the repeating unit or building block of the crystal lattice. (Section 12.2)

unsaturated solution A solution containing less solute than a saturated solution. (Section 13.2)

valence band A band of closely spaced molecular orbitals that is essentially fully occupied by electrons. (Section 12.7)

valence-bond theory A model of chemical bonding in which an electron-pair bond is formed between two atoms by the overlap of orbitals on the two atoms. (Section 9.4)

valence electrons The outermost electrons of an atom; those that occupy orbitals not occupied in the nearest noble-gas element of lower atomic number. The valence electrons are the ones the atom uses in bonding. (Section 6.8)

valence orbitals Orbitals that contain the outer-shell electrons of an atom. (Chapter 7: Introduction)

valence-shell electron-pair repulsion (VSEPR) model A model that accounts for the geometric arrangements of shared and unshared electron pairs around a central atom in terms of the repulsions between electron pairs. (Section 9.2)

van der Waals equation An equation of state for nonideal gases that is based on adding corrections to the ideal-gas equation. The correction terms account for intermolecular forces of attraction and for the volumes occupied by the gas molecules themselves. (Section 10.9)

vapor Gaseous state of any substance that normally exists as a liquid or solid. (Section 10.1)

vapor pressure The pressure exerted by a vapor in equilibrium with its liquid or solid phase. (Section 11.5)

vibrational motion Movement of the atoms within a molecule in which they move periodically toward and away from one another. (Section 19.3)

viscosity A measure of the resistance of fluids to flow. (Section 11.3)

volatile Tending to evaporate readily. (Section 11.5)

voltaic (galvanic) cell A device in which a spontaneous oxidation-reduction reaction occurs with the passage of electrons through an external circuit. (Section 20.3)

vulcanization The process of cross-linking polymer chains in rubber. (Section 12.6)

watt A unit of power; $1\text{ W} = 1\text{ J/s}$. (Section 20.5)

wave function A mathematical description of an allowed energy state (an orbital) for an electron in the quantum mechanical model of the atom; it is usually symbolized by the Greek letter ψ . (Section 6.5)

wavelength The distance between identical points on successive waves. (Section 6.1)

weak acid An acid that only partly ionizes in water. (Section 4.3)

weak base A base that only partly ionizes in water. (Section 4.3)

weak electrolyte A substance that only partly ionizes in solution. (Section 4.1)

work The movement of an object against some force. (Section 5.1)

INDEX

- AB_n molecules, 332–33
 Absolute entropy, 800, 801, 802
 Absolute temperature, 403, 578
 Absolute zero, 390
 Absorption, 542, 590
 Absorption spectrum, 987
 Accident prevention, safer chemistry for, 772
 Accuracy, 21–22
 Acetaldehyde (ethanal), 554, 1022, 1024, 1025
 properties of, 431
 Acetaminophen, 1049
 Acetate ion, 63
 Acetic acid (ethanoic acid), 124, 667, 688, 700, 704, 1022, 1025–26
 chemical formula of, 118*n*
 decarbonylation of, 822
 in green chemistry, 773
 hydrogen bonding in, 435
 ionization of, 118
 pH of, 670–71
 production of, 824, 1026
 properties of, 667
 pure (glacial acetic acid), 153
 shape of, 342
 titration with caustic soda (NaOH), 716–20
 Acetic anhydride, 1048
 Acetone (propanone), 150, 457, 460, 520, 554, 555, 1022, 1024, 1025
 Acetonitrile, 430, 551, 553, 573, 600, 1006
 methyl isonitrate converted to, 571, 577–78, 600
 properties of, 431
 Acetylene, 203–4, 329, 822, 949, 1008, 1017, 1022
 production of, 419
 standard enthalpy of formation for, 184
 triple bonds in, 353–54
 Acetylide ion, 948
 Acetylsalicylic acid (aspirin), 4, 111, 127*n*, 377, 697, 747, 1025
 Acid(s), 124–25
 adipic, 102–3, 494
 Arrhenius, 652
 binary, 685–86
 carboxylic, 688–89
 conjugate, 655
 defined, 64
 defined constants for, 1062
 diprotic, 124, 664
 as electron acceptor, 689–90
 factors affecting strength of, 685
 household, 124
 ionic properties of, 124–25
 Lewis, 689–92
 metal oxides reacting with, 266
 monoprotic, 124, 664
 names and formulas of, 64–65
 oxidation of metals by, 133–35
 oxyacids, 686–88, 929
 properties of, 124–25
 reactions of. *See also* Acid-base reactions
 with alcohol, 646
 with magnesium, 134
 with magnesium hydroxide, 128
 relating to anions, 64
 relative strengths of, 656–58
 strong, 125–26, 656–57, 664–66
 in buffered solutions, 711–13
 titrating, 145–46
 weak, 125–26, 656–57, 666–75
 acid-dissociation constant (K_a), 667–68, 670–73, 679–81
 common-ion effect on, 704–7
 percent ionization of, 669
 polyprotic, 674–75, 720–21
 Acid-base equilibria, 650–701. *See also* Aqueous equilibria
 acid-dissociation constant and base-dissociation constant relationship, 679–81
 Arrhenius definitions, 652
 autoionization of water, 658–60
 Brønsted-Lowry acids and bases, 652–58
 conjugate acid-base pairs, 654–56
 H^+ ions in water and, 652–53
 proton-transfer reactions, 653–54
 relative strengths of, 656–58
 chemical structure and, 685–89
 binary acids, 685–86
 carboxylic acids, 688–89
 factors affecting acid strength, 685
 oxyacids, 686–88
 ion product, 659–60
 Lewis acids and bases, 689–92
 electron-pair acceptor/donor concept, 689–90
 metal ions and, 690
 in organic substances, 689
 pH scale, 660–64
 measuring, 663–64
 other “p” scales, 662–63
 of salt solutions, 681–85
 anion reaction with water, 681–82
 cation reaction with water, 682–83
 combined cation-anion effect, 683–85
 solubility equilibria and, 726
 strong acids and bases, 664–66
 in buffered solutions, 711–13
 weak acids and bases, 666–79
 acid-dissociation constant, 667–68, 670–73, 679–81
 common-ion effect on, 704–7
 percent ionization of, 669
 polyprotic acids, 674–75
 types of, 677–79
 Acid-base indicators, 145–46, 663–64
 Acid-base properties, of organic substances, 1007
 Acid-base reactions, 124–30. *See also* Acid-base equilibria
 electrolytes, 126–27
 with gas formation, 129–30
 gas-phase, 654
 neutralization reactions and salts, 127–29
 Acid-base titrations, 714–22
 of polyprotic acids, 720–21
 strong, 714–16
 weak, 716–20
 Acid-dissociation constant (K_a), 667–68
 base-dissociation constant (K_b) and, 679–81
 calculating from pH, 668–69
 calculating percent ionization using, 673
 calculating pH from, 670–73
 for metal cations, 682
 for polyprotic acids, 674
 Acidic anhydrides (acidic oxides), 932
 Acidic solutions, 683–85
 Acid inhibitors, 130
 Acid-insoluble sulfides, 738
 Acidosis, 713
 Acid rain, 268, 758–60, 932
 Acid salts, 680
 Acid spills, 130
 Actinides, electron configurations of, 232–33
 Activated complex (transition state), 577, 582
 Activation, entropy of, 825
 Activation energy, 577–78
 catalysis and, 590, 593, 637, 638
 determining, 579–81
 Active metals, 135
 Active site, 593
 Active transport, 539
 Activity, 888–89
 Activity series, 135–37, 846
 Actual yield, 102–3
 Addition
 in exponential notation, 1052
 significant figures in, 24
 Addition polymerization, 492–93
 Addition polymers, 493
 Addition reactions
 of alkenes and alkynes, 1017–19
 mechanism of, 1019
 Adenine, 459, 1040, 1041
 Adenosine diphosphate (ADP), 814, 944
 Adenosine monophosphate (AMP), 1050
 Adenosine triphosphate (ATP), 814, 824, 944
 Adhesive forces, 438
 Adipic acid, 102–3, 494
 ADP (adenosine diphosphate), 814, 944
 Adrenaline (epinephrine), 108, 552, 698
 Adsorption, 542, 543, 590–91
 Advanced burning, 903
 Air, 113
 combustion in, 83–84
 composition of, 384, 400
 density of, 19
 Air bags, automobile, 83, 398–99
 Air pollution, 592
 in Mexico City, 778
 Alanine, 689, 1030, 1031, 1032
 Alanylglycylserine, 1032
 (R)-Albuterol, 1029
 Alchemy, 138
 Alcohol(s), 66–67, 1023–24
 condensation reactions with, 1026
 as functional groups, 1023
 oxidation of, 1025
 reaction of organic acid with, 646
 solubilities of, 521
 Aldehydes, 1024–25
 nomenclature, 1047
 Alizarin yellow R, 664
 Alkali chlorides, lattice energies of, 294
 Alkali metal halides, properties of, 481
 Alkali metal ions, 738
 Alkali (group 1A) metals, 51, 135, 233, 268–72
 group trends for, 268–72
 in ionic hydrides, 923
 ionic hydroxides of, 665–66
 oxidation number of, 132
 as reducing agent, 844
 Alkaline battery, 855–56
 Alkaline earth (group 2A) metals, 51, 135, 233, 272
 group trends for, 272
 in ionic hydrides, 923
 ionic hydroxides of, 665–66
 oxidation number of, 132
 as reducing agent, 844
 Alkalosis, 713
 Alkanes, 66–67, 1008, 1009–14
 cycloalkanes, 1013
 derivatives of, 66–67
 nomenclature of, 1010–13
 reactions of, 1013–14
 structural isomers of, 1009–10
 structures of, 1009
 Alka-Seltzer, 130
 Alkenes, 1008, 1015–17
 addition reactions of, 1017–19
 Alkyl groups, 1011, 1021
 in Friedel-Crafts reaction, 1021
 Alkynes, 1008, 1017–19
 addition reactions of, 1017–19
 in green chemistry, 774–75
 Allene, 379
 Allotropes, 273
 Alloys, 473–76, 964
 common, 473
 defined, 473
 heterogeneous, 474, 475
 intermetallic compounds, 475
 interstitial, 474, 475
 solution, 474
 steels, 474
 substitutional, 474, 475, 476
 Alloy steels, 474
 α -helix, 1033
 α radiation, 43–44, 877, 878, 879, 902, 903, 904
 α -scattering experiment, Rutherford’s, 43–44
 Aluminum (Al), 8, 249, 476, 506
 alloyed with gold, 477
 electrometallurgy of, 862
 electron configuration of, 233
 Lewis symbol for, 290
 oxidation number of, 132
 oxidation of, 136, 857–58
 purification of ore, 733–34
 recycling, 862
 specific heat of, 176
 thermodynamic quantities for, 1059

- Aluminum hydroxide, 734
 Aluminum ion (Al^{3+}), 60
 Aluminum oxide, 862
 American Chemical Society, 52
 Americium–241 606
 Amides, 1028
 Amine group, 689
 Amine hydrochlorides, 680
 Amines, 677–78, 680, 1007, 1028
 reaction with carboxylic acid, 493–94
 Amino acids, 1029–32
 α -, 1030
 amphiprotic behavior of, 689
 chiral, 1030
 essential, 1030
 general structure of, 689
 side chain, 1032
 Ammeter, 873
 Ammonia, 124, 384, 442, 738, 937–38
 as Arrhenius and Brønsted-Lowry
 base, 654
 bond angles, 338
 bonding in, 350
 critical temperature and pressure of,
 442
 in fertilizers, 614, 615
 formation of, 803
 Haber (Haber-Bosch) process for
 synthesizing, 614, 615, 873
 free energy changes in, 810, 813
 hydrogen and, 923
 nitrogen and, 937
 temperature effects on, 615, 631
 as household base, 124
 molecular geometry of, 336
 properties of, 676, 678
 reactions of
 with boron trifluoride, 313
 with water, 655
 sale of, 6
 standard enthalpy of formation for,
 184
 synthesis of, 614, 615, 630–31, 637–38,
 802, 813
 Ammonium chloride, 422
 Ammonium cyanate, 1006
 Ammonium hydroxide, 125
 Ammonium ions, 60, 119
 reaction with nitrite ions in water, 563
 Ammonium nitrate, 516, 517
 Ammonium perchlorate, 929–30, 960
 Ammonium thiocyanate, 168
 Amorphous solid, 465
 AMP (adenosine monophosphate), 1050
 Ampere (A or amp), 15
 Amphetamine hydrochloride, 680
 Amphiprotic substances, 654, 733*n*
 Amphojel, 130
 Amphoteric hydroxides, 733–34
 Amphoteric oxides, 733–34

Common Ions

Positive Ions (Cations)

1+

ammonium (NH_4^+)
cesium (Cs^+)
copper(I) or cuprous (Cu^+)
hydrogen (H^+)
lithium (Li^+)
potassium (K^+)
silver (Ag^+)
sodium (Na^+)

2+

barium (Ba^{2+})
cadmium (Cd^{2+})
calcium (Ca^{2+})
chromium(II) or chromous (Cr^{2+})
cobalt(II) or cobaltous (Co^{2+})
copper(II) or cupric (Cu^{2+})
iron(II) or ferrous (Fe^{2+})
lead(II) or plumbous (Pb^{2+})
magnesium (Mg^{2+})
manganese(II) or manganous (Mn^{2+})
mercury(I) or mercurous (Hg_2^{2+})

mercury(II) or mercuric (Hg^{2+})
strontium (Sr^{2+})
nickel(II) (Ni^{2+})
tin(II) or stannous (Sn^{2+})
zinc (Zn^{2+})

3+

aluminum (Al^{3+})
chromium(III) or chromic (Cr^{3+})
iron(III) or ferric (Fe^{3+})

Negative Ions (Anions)

1-

acetate (CH_3COO^- or $\text{C}_2\text{H}_3\text{O}_2^-$)
bromide (Br^-)
chlorate (ClO_3^-)
chloride (Cl^-)
cyanide (CN^-)
dihydrogen phosphate (H_2PO_4^-)
fluoride (F^-)
hydride (H^-)
hydrogen carbonate or bicarbonate (HCO_3^-)

hydrogen sulfite or bisulfite (HSO_3^-)
hydroxide (OH^-)
iodide (I^-)
nitrate (NO_3^-)
nitrite (NO_2^-)
perchlorate (ClO_4^-)
permanganate (MnO_4^-)
thiocyanate (SCN^-)

2-

carbonate (CO_3^{2-})
chromate (CrO_4^{2-})
dichromate ($\text{Cr}_2\text{O}_7^{2-}$)
hydrogen phosphate (HPO_4^{2-})
oxide (O^{2-})
peroxide (O_2^{2-})
sulfate (SO_4^{2-})
sulfide (S^{2-})
sulfite (SO_3^{2-})

3-

arsenate (AsO_4^{3-})
phosphate (PO_4^{3-})

Fundamental Constants*

Atomic mass unit	1 amu = $1.660538782 \times 10^{-27}$ kg
	1 g = $6.02214179 \times 10^{23}$ amu
Avogadro's number	N_A = $6.02214179 \times 10^{23}$ /mol
Boltzmann's constant	k = $1.3806504 \times 10^{-23}$ J/K
Electron charge	e = $1.602176487 \times 10^{-19}$ C
Faraday's constant	F = 9.64853399×10^4 C/mol
Gas constant	R = 0.082058205 L-atm/mol-K = 8.314472 J/mol-K
Mass of electron	m_e = $5.48579909 \times 10^{-4}$ amu = $9.10938215 \times 10^{-31}$ kg
Mass of neutron	m_n = 1.008664916 amu = $1.674927211 \times 10^{-27}$ kg
Mass of proton	m_p = 1.007276467 amu = $1.672621637 \times 10^{-27}$ kg
Pi	π = 3.1415927
Planck's constant	h = $6.62606896 \times 10^{-34}$ J-s
Speed of light in vacuum	c = 2.99792458×10^8 m/s

*Fundamental constants are listed at the National Institute of Standards and Technology Web site:
<http://www.nist.gov/physlab/data/physicalconst.cfm>

Useful Conversion Factors and Relationships

Length

SI unit: meter (m)

$$\begin{aligned}1 \text{ km} &= 0.62137 \text{ mi} \\1 \text{ mi} &= 5280 \text{ ft} \\&= 1.6093 \text{ km} \\1 \text{ m} &= 1.0936 \text{ yd} \\1 \text{ in.} &= 2.54 \text{ cm (exactly)} \\1 \text{ cm} &= 0.39370 \text{ in.} \\1 \text{ \AA} &= 10^{-10} \text{ m}\end{aligned}$$

Mass

SI unit: kilogram (kg)

$$\begin{aligned}1 \text{ kg} &= 2.2046 \text{ lb} \\1 \text{ lb} &= 453.59 \text{ g} \\&= 16 \text{ oz} \\1 \text{ amu} &= 1.660538782 \times 10^{-24} \text{ g}\end{aligned}$$

Temperature

SI unit: Kelvin (K)

$$\begin{aligned}0 \text{ K} &= -273.15 \text{ }^\circ\text{C} \\&= -459.67 \text{ }^\circ\text{F} \\K &= \text{ }^\circ\text{C} + 273.15 \\^\circ\text{C} &= \frac{5}{9} (\text{ }^\circ\text{F} - 32^\circ) \\^\circ\text{F} &= \frac{9}{5} \text{ }^\circ\text{C} + 32^\circ\end{aligned}$$

Energy (derived)

SI unit: Joule (J)

$$\begin{aligned}1 \text{ J} &= 1 \text{ kg}\cdot\text{m}^2/\text{s}^2 \\&= 0.2390 \text{ cal} \\&= 1 \text{ C}\cdot\text{V} \\1 \text{ cal} &= 4.184 \text{ J} \\1 \text{ eV} &= 1.602 \times 10^{-19} \text{ J}\end{aligned}$$

Pressure (derived)

SI unit: Pascal (Pa)

$$\begin{aligned}1 \text{ Pa} &= 1 \text{ N}/\text{m}^2 \\&= 1 \text{ kg}/\text{m}\cdot\text{s}^2 \\1 \text{ atm} &= 1.01325 \times 10^5 \text{ Pa} \\&= 760 \text{ torr} \\&= 14.70 \text{ lb}/\text{in}^2 \\1 \text{ bar} &= 10^5 \text{ Pa} \\1 \text{ torr} &= 1 \text{ mm Hg}\end{aligned}$$

Volume (derived)

SI unit: cubic meter (m³)

$$\begin{aligned}1 \text{ L} &= 10^{-3} \text{ m}^3 \\&= 1 \text{ dm}^3 \\&= 10^3 \text{ cm}^3 \\&= 1.0567 \text{ qt} \\1 \text{ gal} &= 4 \text{ qt} \\&= 3.7854 \text{ L} \\1 \text{ cm}^3 &= 1 \text{ mL} \\1 \text{ in}^3 &= 16.4 \text{ cm}^3\end{aligned}$$

^aThe labels on top (1A, 2A, etc.) are common American usage. The labels below these (1, 2, etc.) are those recommended by the International Union of Pure and Applied Chemistry (IUPAC).

The names and symbols for elements 113 and above have not yet been decided.

Atomic weights in brackets are the names of the longest-lived or most important isotope of radioactive elements.

Further information is available at <http://www.webelements.com>

** Discovered in 2010, element 117 is currently under review by IUPAC.

List of Elements with Their Symbols and Atomic Weights
